

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Index to Vol. VI.—Motor-Car Journal Supplement.

ACCELERATOR, Foot *v.* Hand Control, 846, 899, 917, 937, 957.
Accessibility, 5 6.

ACCESSORIES, SOME NEW.
Adam's Motor Jack, 759.*
Amac Contact Maker, 827,* 948.*
Arbel Steel Wheel, 149.*
Argyll Carburettor, 970.*
Ashtead Accumulators, 1068.*
Auto Patent Roller Bearings, 157.
Baker Change Speed Gear, 428.*
Bartlite Generator, 84.*
Beau Non-Skid, 744.
Begbie-Audin Radiator, 18.
Brooke Carburettor, 681.*
Brown and Barlow Carburettor, 599.*
Brown and Barlow Switch, 1012.*
Bullock Ignition Device, 607.*
Caron Ignition Device, 989.*
C.G.V. Steering Gear, 762.*
Challenge Non-Skid Device, 764.*
Chenard-Walcker Automatic Carburettor, 31.*
Clarke's Ejector, 627.*
Coesor Petrol Gauge and Densimiter, 1067.
Cowey Speed Indicator, 1067.
Cradle, Motor-Car, 136.
Cremorne Carburettor, 136.
Crown Tyre Protector, 216.
85.*
Curtis's Seat, 51.*
Dependence Tail Lamp, 490.
Dinin Plug, 1041.*
Doherty Radiator, 158.*
Dunhill's Front Glass Screen, 454, 808.*
Durandal Puncture-Proof Band, 244.*
Economic Carburettor, 219.*
Eisemann High Tension Magneto Ignition, 996.
Eureka Patent Interchangeable Spanner, 995.*
Everright Charging Set, 10.*
Fafnir Petrol Engine, 808.*
Forman Motor, 955.*
Fouillaron Change Speed Gear, 15.
Friction Clutch, 323.
Gamage's Tyre Lever, 18.*
G.A. Speed Regulator, 325.*
Gare Patent Tyre Setter, 85.*
G.B. Tyre Vulcaniser, 436, 828.*
Goldburgh Plug, 586.*
Grouvelle Arquembourg Motor-Cycle Carburettor, 868.*
H.F. Vulcaniser, 84.*
Hoffman Ball-Bearing Hub, 135.*
Jupiter Acetylene Headlight, 828.*
Kennard Valise, 471.*
Lamp de Luxe, 18.
Little Giant, 161.*
Lucas Non-Skids, 874.
Mercedes Coil Clutch, 990.*
Montgomery Silencer, 861.*
Motor Whistle, 824.*
Napier Valves, 646.
Pereno Double Sprag, 646.*
Peugeot Automatic Carburettor, The New, 756.*
Polkey Head Light, 606.*
Pompeesi Tyre Inflator, 222.
Robinson Spring Wheel, 472.
Sampson Head Light, 994.*
Sclaverand Mechanical Tyre Pump, 83.*
Silencer for Motor-Cycles, 35.
Simplex Ignition, 671, 842.*
Smith and Son's Speed Indicator, 157.
Sparking Plugs, 265.* 292.* 511.*
Stanley Silencer, 136.
Stepney Spare Motor Wheel, 328.
Universal Silencer, 606.*
Van Raden's Trembler Coil, 782.*
Veeder Odometer, 1012.
Willard's Lamps, 138.*
Zanardini Lamp, 510.*
Zubolof Ignition Device, 989.*

Accumulators, Notes on Recharging, 350.
Accumulators, Sulphated, 310.
Act, The Motor-Car, 67, 296, 336, 531, 978.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, MARCH 5, 1904. [No. 261.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

IN March, 1899, the *Motor-Car Journal* began its career, or rather continued the work done for automobilism by "Industries and Iron," which was the successor of the old "Mechanics' Magazine," that chronicled the early developments in the movement towards motor-cars. Thus the *Journal* has worthy associations, and can look back on some distinguished predecessors, though its name is as modern as the movement it serves. At the beginning of the sixth volume—the Index to that just closed will be published next week—we may be pardoned for reminding our readers of this interesting fact. Many changes have taken place in the movement since we wrote our first Comment, but one tendency we note with considerable satisfaction, viz., the desire on the part of the public and the trade to recognise the worth of British productions and also the ability of British firms to turn out automobiles as good and as well finished as any foreign manufacturers. This is a matter of congratulation, and the day is not far distant when motor-cars of which every part has been made in England will be in the majority, should a census of automobiles ever be taken in this country.

◆ ◆ ◆

A Question Awaiting Answer.

THURSDAY'S meeting of the A.C.G.B.I. promises to attract such a large number of town and country members that the committee have wisely decided to convene it at the Institution of Mechanical Engineers. Several notices of motion have been submitted for discussion and there is every prospect of a series of acrimonious debates on the various points raised. Many questions will doubtless be asked, and already the report in the "Club Journal" as to the additional grant to Mr. C. Johnson's testimonial fund is leading members to ask the reason for such gift. Apparently the matter was revived by a letter from Mr. Johnson himself; but even that does not warrant a monetary addition to a testimonial of which we thought the last had been heard long ago.

◆ ◆ ◆

Earl Shrewsbury's Resolution.

ONE of the questions raised—fortunately one of principle rather than of mere personal pettiness—is to be brought forward by the Earl of Shrewsbury and Talbot, who is not a candidate for the committee and whose interest is concerned solely with the prestige of the A.C.G.B.I. We have had the pleasure of a chat with his lordship on the subject of his resolution, and he has certainly strong arguments to advance in support. In fact, the trade should not feel that he is desirous of ousting themselves from a share of direction in the affairs that concern them; he is only anxious to clear the organisation from all suggestions as to commerce, and to enable it to continue its assertion of its place at the head of the sport and the industry.

Consideration for all.

SUPPOSING chairmen and directors of automobile companies, as well as active partners in motor-car firms, were removed from participation in the counsels of the club! The trade would not suffer, for Earl Shrewsbury also proposes the appointment of sub-committees to deal with racing, trials, etc. Upon these the voice of the trade would largely predominate, and the votes of the smaller firms would count as well as those of the few larger concerns whose several representatives too frequently sway the voting. This is a point that will weigh with many members in the provinces, and a goodly number have already sent proxies to Earl Shrewsbury in support of his resolutions.

◆ ◆ ◆

A good Case.

MEANWHILE the ballot is proceeding, so that the adoption of the Earl of Shrewsbury's resolution will have no effect upon the result of the election. That, however, need not hinder the members of the A.C.G.B.I. who desire to see the Club prestige maintained from expressing themselves clearly in favour of the elimination of the trade element at the meeting; in fact, a large measure of support is already assured, and, as we have said, the supporters of the resolution may be expected to make out a good and impressive case.

◆ ◆ ◆

A Railway Motor-Car Service.

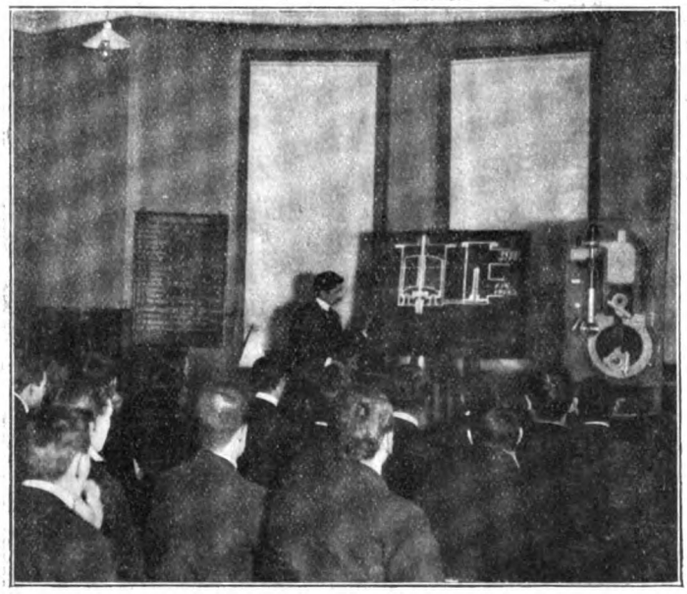
ON Tuesday the Great Western Railway Company inaugurated a new service of motor-cars, connecting their main line at Slough with Beaconsfield, by way of Stoke Road, Stoke Poges, Farnham Royal, and Farnham Common. A trial trip was made on Monday, the party comprising Mr. Morris, superintendent of the Great Western line; Mr. Hart, superintendent of the London section; Mr. Coventry, of the genera manager's office; and others. The fast train left Paddington at 11.15 a.m., the motor-car started from Slough at 11.50 and reached Beaconsfield at 12.35, the journey by road having taken three-quarters of an hour. It is made through a lovely rustic country, pleasant even in winter, in summer delightful. As a beginning the cars are to run three times daily in each direction between Beaconsfield and Slough; but within a week an additional car will run between Slough and Farnham Common at frequent intervals, being timed to catch fast trains to and from London. It is understood that the company intend to make Slough a motor-car centre, establishing workshops there for the repair of cars running in the district.

◆ ◆ ◆

Irish Ostriches.

IT is somewhat surprising to learn that five county councils in Ireland are playing the ostrich with regard to the motor transit scheme suggested for the Emerald Isle. They are those of Antrim, Kerry, Donegal, Meath, and Kildare, the obstinacy of the latter being particularly incomprehensible in view of the automobile education enjoyed by the locality last year. The Irish Secretary is proposing an alteration in the regulations so that the motor vehicles will be able to have a tare weight of three tons, with trailers of eighteen cwts., and to

Digitized by Google



proceed at a rate of ten miles an hour. All the county councils with the exception of this quintette have assented We trust that either these will change their opinions or that the principle of the greatest benefit of the greater number will prevail in high circles.

◆ ◆ ◆

Technical Education.

NOT only in London, but also in the provinces, increased care is being given in the provision of instruction in motor-car driving and practice, and the attention now being devoted to technical instruction in this branch will have a good effect in the development of the industry. The accompanying illustration shows the students listening to a lecture on the carburettor by Mr. H. J. Taylor at the Battersea Polytechnic, which was visited last week by the Prince and Princess of Wales. Every Monday, Tuesday and Saturday this class is held for theoretical work, and on Wednesdays, Thursdays, Fridays and Saturdays workshop instruction is carried on. Driving lessons are given on the road daily, and altogether the experiment is likely to be productive of much good.

◆ ◆ ◆

Automobile Instruction at Battersea Polytechnic.

◆ ◆ ◆

Signposts.

THE Roads and Bridges Committee of the Glamorgan County Council, at their meeting at Cardiff last week, had under consideration the question of putting up signposts in accordance with the requirements of the new Motor Car Act. The clerk (Mr. Mansel Franklen) remarked that the Council were already in default for not having carried out the work. The county surveyor (Mr. Lloyd Edwards) said that about 300 signposts would be required. It was agreed that £1,000 should be set aside for the work. Of course, such expenditure seems somewhat heavy, but against it must be put the income derived from registrations and license fees. When these are taken into account, the actual difference will not be so great as may appear from a superficial glance at the figures.

◆ ◆ ◆

For Travellers.

COMMERCIAL travellers, more than any other class, may be expected to realise the advantages to be derived from the regular use of the automobile in the way of business. They are thus saved many wearisome waits at railway stations, especially on cross country journeys, by its use. The motor car becomes a positive economy in time when, having finished their business, instead of waiting about for several hours till the next train, travellers can get on to their destination, making new calls on the way. Several of the leading firms are providing their travellers with motor-cars, and Messrs. Allsopp and Sons, Limited, the brewers, are finding the use of the motor-cars by some of their drummers as great an economy as many of the Burton brewers are realising that the motor vehicle for the conveyance of heavy traffic is an advantage over the system of horse haulage.

◆ ◆ ◆

Side-Slip Competition.

A SCORE of entries in the side-slip competition organised by the A.C.G.B.I. give promise of a good test, from which should evolve some satisfactory device for saving motorists from one of their worst enemies. On another page we give a list of entries, and it is evident that not only are commercial firms paying attention to the subject, but enthusiastic motorists not engaged in the business are studying the matter. Hence the hope that the forthcoming trials may prove of tangible benefit to the whole movement.

◆ ◆ ◆

Educational Visits.

WE are now within measurable distance of the official exhibition of the year, viz., that to be held at the Royal Agricultural Hall from the 19th to the 26th inst. That the number of trade visitors will be unprecedented is evident from the interest taken in the event by the railway companies, many of whom are arranging for special excursions from the provinces. From several towns trips are being organised by leading motor-car firms with the view of providing an opportunity for their employees to become acquainted with the latest developments in motor-car work. Education of this kind is useful, and no better opportunity for gaining such knowledge could be found than will be offered at the forthcoming show.

◆ ◆ ◆

Motor-'Buses at Torquay.

AT Torquay the motor-omnibus service has proved a success, even beyond the usual sanguine expectations of the promoters. During the first nine weeks over 20,000 passengers were carried, the uniform fare being 2d. On the other hand, the amount paid for fuel and wages in the same period averaged from 3·67d. to 6·03d. per mile run, the average being 4.54d. The cost of renewals was 0·39 pence per mile, and if the cost of lubricants, tyres, etc., is added, the total comes to 5·48d. per mile. These figures amount to considerably less than half the revenue received in fares, and point to a successful future for the company which has had the enterprise to give Torquay its motor-'buses.

◆ ◆ ◆

Innkeepers' Obligations.

THE Bench at Haywards Heath have rightly warned inn and hotel keepers that their obligations are concerned with ministering to the wants of customers without distinction of liquid. The licensees of the Black Swan inn had, it was alleged, declined to serve a motorist with tea, and when the question of the renewal of the licence came before the Bench the matter was postponed for a month. It came again before the court on Monday, when it was stated that the tenant had received notice to quit. The Bench observed that licences would not be granted if people who asked for tea and other non-alcoholic drinks were not served. This is the right line to take; the next thing will be to secure that such drinks are served at reasonable prices.

◆ ◆ ◆

Views on Traffic.

BEFORE the Royal Commission on locomotion and street traffic in London, Col. R. E. Crompton has been giving his views. These are fairly well known to motorists, and consist mainly in urging the authorities to carry out with more stringency the existing regulations as well as to obtain greater powers with regard to heavy vehicles delaying traffic by stand-

Digitized by Google

ing in the streets at any hour of the day. On the same day that Col. Crompton gave his evidence, Earl Russell spoke as to the most unsystematic manner in which streets are "up," to the utter confusion of the ordinary traffic. He advocated the provision of more viaducts, similar to Holborn Viaduct, and the construction of wider thoroughfares, so that more traffic could be safely carried on along the main roads from London to the various suburbs. The third witness was Mr. Rees Jeffreys, who urged upon the commissioners his views with regard to the creation of new streets around London, with a view to ease the existing congestion of traffic.

◆ ◆ ◆

The Yorkshire Club.

We are glad to learn that, with the advent of more local centres like that formed at Huddersfield, there is an opportunity for the Yorkshire Club to fully justify its title. Our impression as to the membership being mainly confined to Leeds, where are the headquarters, has been removed by a letter from Mr. A. W. Dougill, the hon. secretary, who informs us that there are a large number of members in Bradford, Harrogate, Halifax, Barnsley, Bridlington and Sheffield. In one of these towns, at least, there is a local club, so that there is evidently a little overlapping. As the idea of local centres extends, however, the fear of possible irritation which such may cause will diminish.

◆ ◆ ◆

Motor Cars in Essex.

Sometimes the local authorities of Essex get excited, and when such a frame of mind occurs, it is generally in connection with the automobile, which is apparently too progressive for the gentlemen of antiquated minds who seem to have been selected to govern the affairs of that somewhat flat county. At Chelmsford, the Road Committee has been recommending the Council to ask the Local Government Board to make regulations restricting the speed of motor-cars in the borough to ten miles an hour. This was stoutly defended by some very earnest advocates, and it was only after a hard battle that the matter was referred back to the committee to reconsider. Such a rebuff should have the effect of inducing them to listen to reason or perhaps exercise a little of that virtue on their own behalf. The County Council elections which are taking place in Essex are also arousing some interest in the motor-car, and at Great Baddow, the Rev. A. J. Sacré, who is a candidate, has been waxing eloquent over the recent decision of the County Council to facilitate business by the purchase of a motor-car for the surveyor. He has just assured a meeting that he will not ask the ratepayers to put their hands into their pockets and buy him the motor-car. In fact, the motor-car idea as carried through by the County Council was, according to the reverend gentleman, an absolute disgrace. An intemperate view such as that should lead the electors to vote for the other candidate. We say this, of course, from an automobile point of view, knowing nothing and caring less for the politics of either gentleman.

As mentioned in a recent issue, a public motor-omnibus service has recently been started between Leipzig and Merseberg, Germany. The cars used are built Messrs. Stoewer Bros., of Stettin. The above illustration is reproduced from a photo taken in the town of Stargard, Pomerania, showing one of the buses after having made a trial trip, through snow and ice. The distance from Stettin to Stargard, about 25 miles, was covered by the vehicle, with a full load of 16 persons, in two hours.

◆ ◆ ◆

Wait till March 26th.

Attempts made to restrict trade or to cause makers to act according to the wishes of a few active spirits must always fail, and, in view of the present agitation that is being sedulously fostered by a certain section of the automobile industry, we would point out that, the shackles of Parliament having been overthrown, the trade is not likely to harness itself in its own fetters. Freedom to act in their own interests is one of the secrets by which business firms have succeeded in the past; it is the pivot of prosperity for the future—especially in the case of an industry that is practically a new one and one the zenith of which is still afar off. Hence we are not surprised to

Digitized by Google

earn that the suggested Bond has not been received with enthusiasm and that most of the leading firms are adopting a waiting policy. They naturally prefer to await the test of the Agricultural Hall show as the business show of the year. There are not a few firms which depend on this annual event for sufficient enquiries and orders to keep their commercial and industrial staffs busy during the greater part of the following twelvemonth.

◆ ◆ ◆

A Ladies' Day at the Exhibition.

THE invitation of Mr. C. Cordingley to the Ladies' Automobile Club to hold a ladies' day at the Agricultural Hall has evidently been appreciated. Lady Cecil Scott Montagu has informed him that Mrs. Gerard Leigh, the hon. secretary of the club, is making arrangements in connection with the matter, and the members of the club will doubtless be glad of so excellent an opportunity of adding to their technical knowledge of automobilism.

◆ ◆ ◆

Glasgow to London Trial.

UNDER the auspices of the Scottish Automobile Club (Western Section), another reliability trial for touring cars will take place from Glasgow to London, on May 19th and 20th next. Compulsory stops will be made at Penrith, Leeds, and Stamford, otherwise it will be a non-stop tour. Only one car of any specific make, type, or horse power will be allowed to be entered, and entries must be to hand with Mr. R. J. Smith, 59, St. Vincent Street, Glasgow, by the 13th prox. Hill-climbing competitions will be arranged, and certificates will be granted in respect of each vehicle completing the trial. The non-stop gold medal will also be awarded in each class, and for the hill-climbing competition the following formula will be the basis of the marks given:—

$$\frac{(w \times 60 \times L) + (W \times h) + \frac{(W \times v^2)}{2}}{a \times n \times s \times \left(\frac{G}{D\pi}\right)}$$

w = Laden Weight of car in tons.
L = Length of hill.
W = Laden Weight of car in lbs.
h = Height of hill.
v = Velocity in feet per second.
a = Area of piston in square inches.
n = Number of cylinders.
s = Stroke in inches.
G = Gear ratio or number of revolutions of engine for one revolution of road wheel on lowest gear.
D = Diameter of road wheel in feet.

◆ ◆ ◆

Balloons and Airships.

OF historic importance, as well as of popular interest, will be the display arranged by the Aero Club in connection with the forthcoming Exhibition. The fact that the War Office is assisting in the matter will ensure the presence of some very notable exhibits, while the new English airship, which will be seen for the first time, constitutes another factor which will make for the success of the display. It is very evident, from the inquiries daily being received at the offices of the Exhibition, that public interest is growing, and that the attendance will be far beyond anything previously seen at an English automobile show.

◆ ◆ ◆

Pneumatic Tyres

MR. SIDDELEY'S paper on pneumatic tyres, summarised on another page, is a valuable contribution to a subject of practical interest to the motorist. In the course of the discussion Mr. Cozens-Hardy emphasized the disadvantage of using tyres of too light weight; Mr. G. H. Thrupp spoke favourably of the Samson-Hutchinson non-skids; Mr. Staplee Firth asked for a method of protecting tyres against damp and rust, and Mr. Chambers drew attention to the form of guarantee given by tyre manufacturers. In his reply Mr. Siddeley dealt fully with the practical point raised by Mr. Firth. In his opinion, a great deal of the rust arose from the manufacturer putting the tyres on the rims before they had been properly painted inside. Even the best makers often had the tyres put on before the rims were properly painted. Mr. Firth had also mentioned blistering, which was frequently due to improper vulcanisation. In a moving tyre there was an enormous amount of friction, and the rubber quickly ground itself into powder and gradually formed a blister. It was very dangerous to go through two or three layers of rubber before sending the tyre to the repairer—a note of warning that should be taken seriously by all motorists.

◆ ◆ ◆

Motor-Van Users.

AS will be seen from the report on another page, the Motor Van and Wagon Users' Association is now in working order, and we may soon expect that it will be defending the rights of users of heavy vehicles as the Motor Union has been looking after the position of owners of light cars. The election of a president and a chairman has been postponed; the hon. treasurer is Col. Crompton; the secretary, Mr. Rees Jeffreys; and Mr. Firth's appointment as solicitor will be an assurance to users of heavy vans that their legal rights will be energetically looked after.

◆ ◆ ◆

A Guide to the Exhibition.

NEXT week we shall publish a Guide to the Motor Car Exhibition, with a list of the exhibitors in the various sections, viz., the Arcade, King Edward's Hall, the Great Hall, the Minor Hall, the Galleries, the North Annexe, the Berner's Hall, the Grand Lounge, etc., as well as particulars of the Club Rooms and other apartments of interest to automobilists.

AS we go to press we learn that the Chamber of Deputies has agreed to allow the French Gordon Bennett eliminating trial to be held over the course selected in the Argonne.

EXHIBITORS at the forthcoming show requiring electric light should make early application direct to the Agricultural Hall Company. This is all the more necessary in view of the enormous quantity of current that will be required.

CLIMBING flights of steps by motor-car in the grounds was one of the amusements at the Crystal Palace last week. A 25-h.p. Gobron-Brillie and a 12-h.p. Lanchester each mounted a flight, the gradient of which is stated to be 1 in 3.

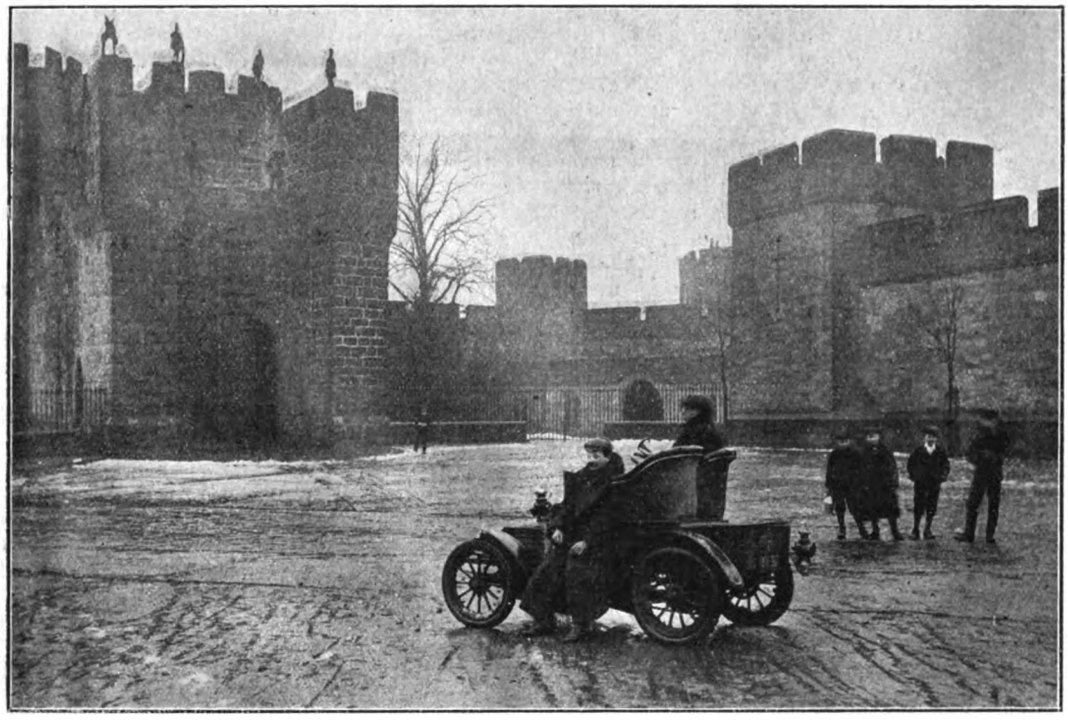
FOR the distribution of "The Daily Chronicle" in the Metropolitan area on Monday a motor-car service was organised by the Great Central Garage Company, Limited. Twenty cars bore the papers to every corner of the great city and its adjacent parts.

GOOD progress is, we hear, being made with the construction of the three Wolseley racers for the Gordon Bennett eliminating contest. It is reported that the four-cylinder engines will develop about 90-h.p., and that the cars will be fitted with specially-shaped aluminium bodies with the view of reducing the air resistance to a minimum.

RACING motorists will regret to learn of the death of Levegh, which has just taken place at Pau. Two or three years ago Levegh, whose real name was Velghe, was one of the foremost *chauffeurs* in France, leading the Mors vehicles to success in many noticeable events. In the first Paris-Ostend race he ran a dead heat with Girardot, while in 1900 his successes included the winning of the Nice-La Turbie and Paris-Toulouse races.

THE statements made as to the attendance at the Crystal Palace give rise to many reflections. Exhibitors and their attendants passed the turnstiles each day, and many entered and re-entered the Palace with a freedom that must have added considerably to the total of visitors. Season ticket holders in connection with the Palace number, we believe, about 20,000, and altogether the census of visitors to the building by no means represents the actual number really concerned with automobilism.

Digitized by Google



A WINTRY RUN TO EDINBURGH.

THE DEBUT OF THE 6-H.P. "WOLSELEY."

IT is over now, but, had we known the severe weather to be experienced on the trip, it is more than probable that the invitation of the Wolseley Company to assist in what may be termed the christening of their new 6-h.p. vehicle would not have been accepted so readily. So many "men of moderate means" are, however, looking for a reliable two-seated car, and the proposed trip offering a splendid opportunity of putting the new 6-h.p. Wolseley through its paces, assent was given and preparations made for a journey from London to Edinburgh. It may here be explained that there was no intention of attempting a non-stop run or of establishing a new record between the two capitals—the car had to go to Edinburgh, and so it was arranged that it should make the trip under its own power by road.

A start was made from the offices of the *Journal* in Shoe Lane late in the afternoon of Thursday of last week, the car, in addition to its driver and passenger, carrying a full supply of spare parts in order to be prepared for possible emergencies. Progress was somewhat slow through the London traffic, but ere long the Metropolis, with its never-ending line of 'buses, tramcars, and cabs, was left behind, and the open country reached. Darkness brought with it a cold nip in the air, the intensity of which was increased by a quick run along the familiar road through Potter's Bar, Hatfield, and Wellwyn to Stevenage, where a stop was made for tea. From Barnet we had encountered many stretches of road in the hands of the road-menders, and it made us fear for the tyres as we ran over many a long patch of freshly-laid unrolled stones. It had been intended to make for Grantham ere resting for the night, but the truth of the old saying was once again brought home to the travellers, for at Baldock a wrong turn was taken—a mistake which added fully twenty miles to the trip, and, instead of Biggleswade, we found ourselves at Royston, well on the way to Cambridge. There was nothing for it except to strike across country to regain the North Road, and it was close upon nine o'clock when we pulled up at the Ivel Hotel for petrol. Smiling Dan Albone was, of course, on the scene, wearing an extra smile as a result of the success of his agricultural motor in a ploughing competition at Chester that day. Off again through Eaton Socon, Buckden, noted for its palace of the Bishops of Lincoln, and Stilton, of noted cheese fame, we buzzed merrily along the road, entirely deserted save for the hundreds of rabbits, which, startled by the motor-car, scampered along for their lives. At Stamford, ninety miles from London, a halt was called for the night and the resolve made for an early start on the morrow.

On Friday morning the outlook was anything but propitious—a thin layer of snow was on the ground, while the dull sky gave promise of a further plentiful supply. Stamford is a quaint old place, but with over 300 miles between us and our destination, time did not permit to linger. So, after replenishing the petrol and water tanks, the journey was resumed shortly before 10 a.m. Once in the open country, the outlook was indeed bleak, and the whiteness of the snow-covered landscape was most trying to the eyes. Good progress was, however, made through Colsterworth, the birthplace of Sir Isaac Newton, to Grantham. A sharp rise out of this old town brought us to Foston, the only incidents on the way to Newark being stoppages for restive horses. Here a short rest was made, the interval being spent in a brief examination of the splendid ruins of the ancient castle. There were no signs of snow at this point, but, instead, we had to travel along wet, heavy roads which quickly covered the car with mud. An hour's run, however, saw us another twenty miles on the way, at Retford, and at 1.45 p.m. we pulled up at Doncaster for lunch, after passing the famous racecourse, 163 miles of the journey having thus been completed with no more startling incident than the killing of a too venturesome rabbit. Leaving Doncaster at 3 p.m. some difficulty was experienced in discovering the proper road to take owing to the scarcity of finger-posts. The result was that we missed the shortest way to Wetherby journeying *via* Tadcaster, reputed for its ales, the recompense for the detour being a glimpse of that popular and apparently thriving resort, Boston Spa. For some miles we had, judging from the imprint of its tyres on the muddy roads, been following on the trail of a motor-car. The automobile was discovered outside an hotel at Boroughbridge, a little town in the West Riding; it proved to be a Miesse steamer, and, as its passengers had repaired within the hotel for tea, we decided to follow suit. Though a nasty blinding sleet had now commenced,

In front of the Barbican of Alnwick Castle.

Digitized by Google

the day's work was not at an end, and, after lighting up the lamps, Bee, the driver, once again took his seat at the wheel, and the passenger, with a longing look at the warm fire, prepared himself as best he could for the fray. The engine, however, seemed to enjoy being out in the storm, and, without a misfire, propelled its load along at a steady pace, unmindful of the pools of water on the road through which we splashed to Northallerton, where a brief halt was made for petrol. Darlington was no sooner left behind than the sleet gave place to snow, and the memory of climbing up a thickly-covered bank to ascertain the way from a finger post on the outskirts of Durham is more pleasant than was the actuality. We were now in the mining district of Durham, a fact indicated not only by the collieries but by the large number of miners we met on the dark roads who had apparently been imbibing "not wisely, but too well." Across Framwellgate Moor to Chester-le-Street —where we were stopped by a police-sergeant anxious to see if our rear number-plate was properly illuminated, a point on which the Durham and Northumberland police appear unwarrantably keen — we went, and soon afterwards tramlines indicated that Gateshead was reached. A charge of fourpence was made to allow the car to cross the High Level Bridge into Newcastle-on-Tyne, which city we entered shortly before midnight. We had travelled 183 miles during the day—not a bad total for a 6-h.p. car, especially in view of the bad weather and roads encountered—and we were naturally ready for food and shelter. Both were, however, denied us for some time; two or three hotels had no accommodation for the car, another, which had a stable, was full. It was only after interviewing half a dozen policemen that we were directed to Messrs George and Jobling's garage, which, while a large and well-equipped establishment, is located in a somewhat out-of-the-way corner very difficult for strangers to the city to find. Cold and wet as we were, our first impressions of Newcastle were of anything but a pleasant character, for close upon an hour elapsed ere we were able to settle down to a well-earned supper.

The poets who from time immemorial have waxed enthusiastic on the beautiful snow, and who have written odes in its praise, were assuredly men who did not live in large towns. Had it been possible for them to walk the streets of Newcastle on Saturday morning, especially with a long road journey before them, poetry would have been totally inadequate to express their thoughts and feelings. Snow was falling, and, melting as it fell, added to the slosh of the already muddy roads. The morning papers, too, gave long accounts of severe snowstorms on the Border, so that altogether the prospect was of a most cheerless character — a prospect which, after leaving Newcastle at 9 a.m. and getting only as far as Gosforth, a couple of miles out, was not improved by the engine beginning to misfire. Eventually it ceased to work at all, the car coming to a standstill immediately by the side of a traction engine which had sunk up to its axles in the road. Never have we driven across such a vile stretch as was encountered at this point; what with being under repair and at the same time covered with a layer of four to five inches of melted snow and mud, the result of the heavy downfall of the previous day, the road had proved impassable to the traction engine, and, what was worse, had pulled up the sturdy Wolseley from its invasion of the Border country. A more desolate-looking spot for a stoppage to occur could hardly be imagined. Ankle-deep in mud we went as we descended from the car, and when the bonnet was lifted the cause of our undoing was at once discernible, the sparking plug and front end of the engine being plentifully bespattered with the slush from the shocking road over which we had travelled. This cleared away, the motor, to our great relief, readily responded to the turning of the starting handle, and, with a part of our copy of the *Journal* pressed into service as a shield to the plug, we restarted on our way.

For a time both the roads and the weather improved, and our spirits likewise rising, a rapid run was made through the mining districts of Seaton Burn and Stannington into Morpeth. Time, unfortunately, did not permit to explore the ruins of the latter's ancient castle nor to visit the interesting old parish church. Its winding streets were safely negotiated, and, once out into the open country, the gradually ascending gradient gave evidence of our approach to the hilly district of the Borderland, which was covered with a thick white mantle of snow. According to our route guide rather over 100 miles lay between us and our destination. Arriving, however, at a point where diverged two roads, a finger-post indicating eighty-nine miles to Edinburgh by one and by the other 104 miles, the shorter route was selected, a decision which proved to be anything but a wise one. For fully ten miles the road lay over barren moors, the loneliness of which was enhanced by the deep snow which covered the land. It is no exaggeration to say that at this point the wheels of the car cut a track through seven to eight inches of snow, while on each side of us were deep drifts. Stiff climbs followed dangerous descents in steady succession for many miles, and it was in passing through this bleak country that the toot toot of a motor horn was heard in our rear. Not to be alone in such a desolate-looking land was something, but to meet fellow motorists from London added zest to the encounter. The car proved to be a 12-h.p. De Dion with Mr. J. W. Stocks at the wheel, engaged on a non-stop run from London. As we ran together for some time we learned that they had travelled throughout the night and had so far had good luck. Of course the 12-h.p. was speedier than the 6-h.p., and shortly Stocks drew away from us, only to be overtaken a mile or so further on, he driving his car slowly while one of the passengers filled up the petrol tank. Apparently both of us, in the agreeable encounter, had taken a wrong turning, and instead of saving fifteen miles in the journey from Morpeth to Edinburgh, had added about ten miles thereto, in addition to having chosen the hillier route of the two, for eventually we found ourselves again on the high road to Alnwick. Stocks again disappeared in front of us, but only for a short time, for, on turning a corner, we came across the car by the road side with Stocks busily engaged on some adjustments. It must have been very annoying to him to thus have his non-stop record spoiled, even by such stiff travelling as had been encountered from Newcastle, and to his credit we may say that although the car was stopped, the engine was in motion.

Once again on the main road, which we regretted having left, we scurried along to Alnwick, where the lion-surmounted column apprised us we had arrived in the domains of the Duke of Northumberland. A brief stay was made in this ancient town, which to our mind was far and away the most interesting of the many we passed through on our long journey. Alnwick played a prominent part in the wars with the old Scottish monarchs, to many of whom it was peculiarly fatal. Here it was that in 1093 Malcolm III., with Edward his son, was killed in making an inroad into Northumberland. Here, too, in 1174, William I., invading England with a army of 80,000 men, was encountered, his army routed and himself made prisoner. Even to-day three towering gates, by which the town is entered at different points, and the vestiges of a wall still to be seen in several parts, give evidence of how strongly fortified a town Alnwick was close upon 1,000 years ago. Of the Castle itself much could be written; it is perhaps the best specimen of a Norman stronghold to be found in the country to-day. The entrance to it is through the massive Barbican, which forms the background to the accompanying illustration. Some time was lost in obtaining a photographer to take the picture, and meanwhile the 12-h.p. De Dion passed through on its way north.

It was with many regrets at the short time available that Alnwick was left at 12.30, and passing through a downpour of sleet we pulled up an hour later at the little village of Belford for lunch, to which full justice was done. We had now got out of the snow-covered country, and, after a run marked only by one or two encounters with timid horses, the river Tweed was sighted and Scotland entered about 4 p.m. It was market day at Berwick, and for some miles beyond slow progress was made owing to the way being impeded by cattle and also on account of the roads being once again snow covered, deep drifts extending in many places right across the track. The scenery at

Digitized by Google

Grant's House and Cockburnspath was beautiful, the road and railway running together for miles between sharp rising hills. At last the welcome sign "30 miles to Edinburgh" was seen, and with the hills and snow left behind, we buzzed along a splendid road to Dunbar and East Linton. Here a stop was made for water and to light up the lamps, darkness having overtaken us. Little now remains to be said; only 22 miles lay between us and our destination, and, as if aware of the approaching termination of its task, the engine seemed to "pull" better than ever. Through Haddington, famous as the birthplace of John Knox, Levenhall, Musselburgh, and on to Portobello we went, and at a few minutes to eight we drove right into the motor-car exhibition in the Waverley Market, Edinburgh, being immediately surrounded by a thick circle of friends and interested spectators.

Much could be written of the points gleaned during a trip between the two capitals—for example, the ways and charges of hotel-keepers would form an interesting chapter, the varying attitude of the police in the different localities would afford ample material for another, while the variety in the shape, lettering, and utility of mile-stones and finger-posts in the various counties passed through could easily serve as a useful theme. Space does not, however, permit of our dwelling on these points; on this occasion we are concerned with the behaviour of the 6-h.p. Wolseley car which made the 400-mile trip with only the one involuntary stop, and that due to a bumpy, muddy road, travelling over which not only bespattered the sparking plug of the motor, but also the faces of the driver and passenger. Beyond replenishing the petrol and water tanks and the lubricators and tightening up a lamp bracket, the car required no attention whatever. The Dunlop tyres, too, went through without a puncture and without requiring inflation, so that, apart from the severity of the weather, the journey was all that could be desired. As for the car itself, the hill was not met that it could not ascend, and as to its speed, at times we travelled at a rate of 25 miles per hour, the average for the whole journey, the bulk of which was over snow-covered roads, being between 17 and 18 miles per hour.

PHANOMEN.

THE Cheltenham and Gloucestershire Automobile Club will, in future, be known as the Gloucestershire Automobile Club.

AT Maida Vale Mr. Robert Atterton has a garage at 13, Canterbury Terrace, where motorists can have accumulators recharged and be supplied with petrol.

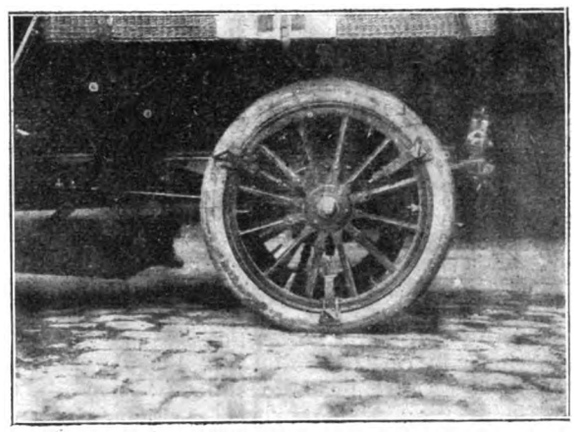
A LARGE public meeting has been held at Tarves, N.B., to urge upon the Great North of Scotland Railway Company the advisability of starting a motor-car service between Udney station and Methlick.

MR. A. W. MACLEOD, of 9, Red Lion Court, Cannon Street, E.C., has been appointed London agent for the "Cottereau" car, for which Messrs. McNeil, Hutchison and Borthwick, of Manchester, are the British representatives.

CONTINENTAL NOTES.

THE German Club has decided to publish an official guide to the Gordon Bennett race; it is to be printed in three languages—German, French and English. It is reported that the Daimler Motoren-Gesellschaft, of Cannstatt, which will have two cars in the race, have constructed six special racers, of which four have engines with cast-iron cylinders, and two steel cylinders. Before the race takes place exhaustive trials of these two types are to be made in order to select the best vehicles. The German De Dietrich Company has, it is stated, decided not to compete in the eliminating trials. M. Jenatzy and the Baron de Caters went for a trial spin over the course last week. Signors Storero, Lancia and Cagno have been selected as the drivers for the three Fiat cars for the Italian team. Official application was made on Monday to the President of the Conseil for authority to run the French eliminating trials in the Argonne in May next. M. Combes personally favoured the application, but stated that the matter would have to be submitted to the Chamber of Deputies.

◆ ◆ ◆



THE anti-skidding competition organised by the Automobile Club de Seine et Oise has been held during the past week. The event brought in thirty-four entries, including two of English origin—the Parsons non-skid and Sainsbury's anti-skid. Considerable interest was shown in the latter, which consists of three U-shaped pieces embracing the rim clear of the tyre and having a connection with the rim more resilient than the tyre. The pieces are adapted to normally rise and fall with the tyre without injuring the latter and so as to have no effect on the direct drive, but when a skid takes place to drag sidewise on the ground without yielding. The competition started on Wednesday, when twenty-eight competitors put in an appearance, twenty of the devices being fitted to cars and eight to motor-cycles. Owing to the fineness of the weather, the original programme had to be altered, a series of trials on the hill of Picardie being substituted. The vehicles were given a flying start of 500 metres, to make the climb on top speed, the point at which it became necessary to change to a lower gear being noted. This test was carried out twice by each competitor, once with smooth tyres and once with the anti-skids fitted. The programme on the 26th, 27th, and 28th ult. consisted of runs on a circular route from Versailles, the distance in each case being 191 kilometres, while on Monday the machines covered a short route of 100 kilometres, after which they were subjected to trials on *pave* and Macadam roads. It may be added that the bulk of the competitors went through the trials successfully, but some little time will elapse ere the report of the jury as to the behaviour of the different devices will make its appearance. Messrs. Cozens-Hardy and O'Gorman were present at the trials on behalf of the A.C.G.B.I. on the two last days.

◆ ◆ ◆

THE Automobile Club of Marseilles held a successful hill-climbing competition on the 21st ult. on a stiff kilometre

Loading the Cars with Ballast.

The Sainsbury Device.

THE ANTI-SKID TRIALS AT VERSAILLES.

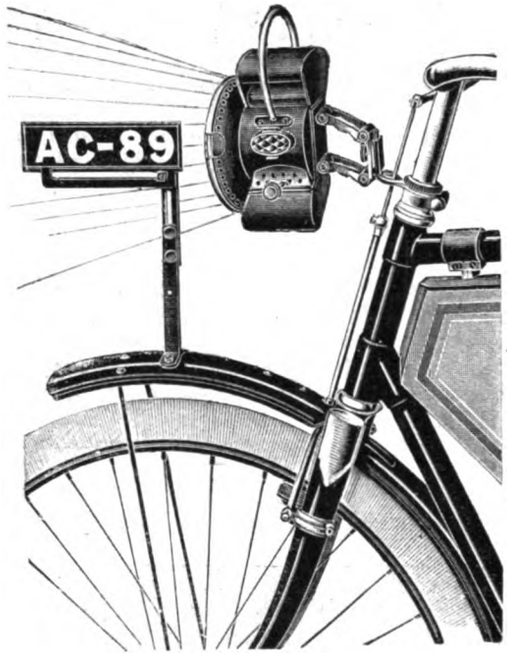
course. The best time of the day was made by Rougier on a 60-h.p. Turcat-Mery, who covered the kilometre in 1 min. 31 sec.

◆ ◆ ◆

REFERENCE was made in this column some time ago to a proposal to establish a motor racing track in the Parc de Buzenval, near Paris. Little has been recently heard of the scheme, but it is now announced that good progress is being made with the project. The estate, which comprises an area of 530,000 metres, adjoins the Saint-Cloud racecourse, and is enclosed by high walls. Buzenval is within easy driving distance of the French capital, the road from Paris being by way of the Champs Elysees and the Bois de Boulogne. Outside the confines of the Parc de Buzenval there is a level grass plain of 150,000 metres. This will be acquired by the promoters of the project. The track is to be several kilometres in circumference, with an absolutely straight run of a kilometre and a half. Moreover, the course will be so arranged that every phase of a race or trial will be visible from any of the stands. A clubhouse will be established on the estate, in addition to ample garage and repairing facilities.

◆ ◆ ◆



THE Dutch Automobile Club has issued a circular giving the formalities to be carried out for the driving of motor-vehicles in Holland. Automobiles that are only to remain in the country a short time can enter free of import duty provided the owner obtains a permit from the Minister of Public Works, which must be presented and countersigned at the Dutch Customs House. Before he can use his car, the tourist must send an application on stamped paper to the Minister of Public Works at the Hague, giving the width, length and weight of the car, the type of engine, the horse-power and the nature of the fuel. In a period of not less than three weeks he receives a permit on stamped paper. It is only available when signed at the Dutch Customs House, so that the application must be made at least three weeks before the automobilist intends to proceed to Holland. Once in possession of the document, duly authenticated by the Customs officers, the tourist has the right to drive his car on the national roads, but if he should venture off on to the provincial roads, his situation will be somewhat complicated. He must send applications on stamped paper for permits to the "permanent deputation" of the provinces of Zeeland, South Holland, North Brabant, Drenthe, and Friesland. The secretary of the Dutch club is able to offer some little consolation by announcing that provincial certificates are not necessary for the six other provinces. A complete specification of the car must again be sent in, together with the names of the owner and his mechanician, and in not less than six weeks the tourist will obtain permits on payment of fees varying from three to eight florins, according to the province. This exhausts the regulations as regards the national and provincial roads, but there also exist local roads for which certificates are needed for Amsterdam, Rotterdam, Groningen and Deventer. These are delivered on application at the nearest police station. The Dutch regulations require the automobilist to carry numbers on the front and back of his car, one of which must be lighted up after dark. The speed limit is fixed at twelve and a half miles an hour on country roads, and five miles an hour "on gradients, in populated centres, on bridges, in fog and after dark," under pain of a maximum fine of fifty florins. With all these formalities it cannot be said that Holland is inviting foreign motorists to tour in their country.

◆ ◆ ◆

SINCE M. Paul Meyan published in *La France Automobile* the method he adopts in protecting his pneumatic tyres, a number of other suggestions have been brought forward. In a recent issue, a correspondent, writing to that paper, explains a means of protection which he has found quite effective and successful. He has taken an old cover of the same size as the new one, and with a sharp knife has made several transverse cuts in the stiffened edges of the old cover. Then deflating the tyre on the rim he has forced the old cover over the new one, and re-inflated the latter. Owing to the pliability gained by the cuts in the edges it is stated that the double cover sits securely and perfectly, protecting and saving the lower one in a satisfactory manner

MOTOR-CYCLING NEWS.

THE accompanying illustration shows a new registration number plate for motor-cycles which has been introduced by Messrs. Brown Brothers, Limited. As will be seen, the plate,

which is made of enamelled iron, is fixed to the front mudguard extension by drilling two small holes and using the fitment supplied. It is adjustable to any height and angle, so that the number on either side is illuminated by the lamp.

◆ ◆ ◆

THE "Vindec Special" motor-cycle placed upon the market by the South British Trading Company, Limited, attracted some attention at the recent show. Since introducing the machine they have fitted some detailed improvements in the addition of a new form of regulator to the air-inlet of the carburettor, which is within easy access of the rider whilst the machine is in operation. The addition of a level gauge attached to the engine enables the rider to determine the exact quantity and condition of the lubricating oil in the crank casing.

◆ ◆ ◆

OUR Directory of Numbers is inclusive of motor-cyclists as well as of those who own cars—a fact we mention as a reminder to those motor-cyclists whose names have not yet appeared in the *Journal* to send their numbers without delay.

◆ ◆ ◆

THE motor-cycle section of the Austrian Automobile Club has decided to organise a reliability trial for motor-cycles between Vienna, Znaim and Brunn during the coming season.

◆ ◆ ◆

THE War Office has affirmed the proposal to include motor bicyclists in the Motor Volunteer Corps, limiting the number, however, to forty.

HOW TO STOP SOME NOISES.

UNDER the most favourable conditions the automobile is not the most noiseless of vehicles, whereupon it behoves the owner of one to at least do what he can to eliminate as much of the noise making as may be possible. Among the important noise creators which are capable of elimination by any one is the rattle of tools which have been carelessly thrown into the place set apart for their storage in a car, and there allowed to dance about as they please to the noisy accompaniment of their own clashing. There are any number of ways of carrying the tools, without which no motor-car should ever be taken upon the road, but of all the ways the worst, but by no means the most uncommon one, is to throw them indiscrimately into a drawer somewhere or another beneath the seats.

When in the natural course of events it happens that even a small tool is required the procuring of it frequently means a complete dislodgement of the passenger is necessary to get at the drawer, and after that the tool seeker has for the time being to assume a more or less uncomfortable position.

A very much better method than this drawer idea is to have one of the leather cases now available in which each tool has its own place, the whole being wrapped up into a roll, then bound with a strap and placed in any part of the car which can be conveniently and readily be got at. Another good idea is to have made a case to fit on to the face of a door, or inside the door of one of the cupboards beneath the seats. This case should consist simply of a piece of light wood, about three-quarters of an inch thick, in which recesses have been cut out right through the wood to fit every size wrench or tool which one ordinarily carries on an automobile. One or more swinging spring clips should be fitted to press upon the tools when they are in position to keep them from falling out or from making a noise, though not strongly enough to prevent the driver, when any tool is required, to find and withdraw it readily. When the tool or tools have been finished with they are just as easily replaced and clipped back in position. If a tool is then seen to be missing it can at once be looked for and restored to its place. This is certainly a much more satisfactory method than travelling a few miles and then finding that in the processs of packing up one or more tools have been left in some unremembered spot. The arrangement suggested has, remarks a writer in the *Automobile Magazine*, of course, the same disadvantage of disturbing the passenger, unless the tool casing is made to fit upon the dashboard or in any other convenient place, but even so, it is a noise preventer of whose efficacy there can be no possible doubt.

Having thoroughly quietened the annoying tool, the next noise maker which should demand prompt attention is the rattling frame or running gear and its attachments, which are the least excusable of all the noises of which a motor-car is guilty. A vehicle running upon pneumatic tyres should make no noise from this cause, but this is far from being the case. Distance rods are a prolific cause of noise. They are generally attached to the frame and to the rear axle by plain studs or bolts of unhardened material passing through holes in the ends of the rods. Whenever the engine is propelling the vehicle the rod is under compression, but whenever the axle or wheel brake is applied the distance rods are under tension, and in this way the bearings of the rods are alternately subjected to stresses which soon tend to develop looseness in them. The constant action of the rear springs, as the vehicle passes over rough roads, and the continual presence of grit, makes the wear very rapid, and as no adjustment is provided at these bearings they become very noisy when the vehicle travels over any but perfectly smooth roads.

Brake bands are generally loosely held when not in action, and the brake actuating mechanism contains a number of unadjustable joints which develop looseness and rattle after continued use. Steering gears which develop loose joints not capable of being taken up contribute to the noise, as do the creaking of spring leaves upon one another and the rattle of spring links when worn. A loose mud guard is also unpleasantly evident to the ear. A scrupulous attention to the details of bearing adjustability, and the lubrication and protection of moving parts, will in the end give a quiet running petrol car.

THE CLUB COMMITTEE.

CONCERNING the election of the new committee of the A.C.G.B.I., which is now in progress, and in connection with which so much wire pulling has been indulged in, we have been requested by many readers who are in doubt as to whom to vote for, to suggest the names of candidates whose presence on that body would be to the advantage of the movement.

Under these circumstances we would respectfully offer the following list, which includes some of the most famous motorists in the country, and the names of many who have helped to bring the movement into the proud position it occupies at the present day.

Allen, John
Aveling, T. C.
Beaumont, W. Worby, M.I.C.E.
Bird, Alfred F.
Bouverie, Hon. Stuart
Boys, Professor C. Vernon, F.R.S.
Butler, Frank, H.
Buttemer, R. W.,
Calthorpe, Everard R., M.I.C.E.
Cordingley, C.
Critchley, J. S., M.I.M.E.
Crompton, Lt.-Col. R. E. B., C.B.
Deasy, Captain H., H.P.
Du Cros, Harvey, Jun.
Edge, S. F.
Edmunds, Henry, M.I.C.E.
Firth, T. W. Staplee
Gorham, J. M., M.I.C.E.
Hill, W. Becket
Hinde, W. Ballin
Holden, Lt. Col. R.A., F.R.S.
Holder, J. A.
Ingram, L. C.
Jarrott, C.
Leonard, W. J.
Lloyd, Major F. Lindsay, R.E.
Manville, Edward, M.I.E.E.
Mayhew, Lt.-Ccl. Mark
Moss, W. E.
Nisbet, J. R.
Ochs, James F.
Pickmere, E. R.
Purchase, E. K.
Redwood, Dr. B., D.Sc., F.R.S.E.
Rolls, the Hon. C. S.
Rose, C. D., M.P.
Rothschild, Lionel de
Rowcliffe, W. E.
Salomons, Sir David L., Bart.
Shaw, C. E, M.P.
Siddeley, J. D.
Smith, E. Shrapnell
Smith, Fred
Stanley, the Hon. Arthur, M.P.
Swinton, Campbell
Thornycroft, Sir J. I.
Todd, R.
Wallace, Roger W.
Whatton, the Rev. A., M.A.
Weguelin, Hugh

MESSRS. S. R. BAILEY AND LAMBERT, LIMITED, are now calling their B. and L. two-seated car the Pelham voiturette.

FOLLOWING the example set by Boston, U.S.A., a course of lectures on automobiles is being inaugurated at the Y.M.C.A. at Buffalo, U.S.A.

MR. G. W. HODGKINSON has had alterations made at his premises in Compton Buildings, Buxton, to enable him to garage cars and also repair the same. He now stocks petrol, oils, and spare parts, and will be pleased to help motorists passing his way.

NOW that the galleries of the Agricultural Hall are fully booked firms intending to be present at the Motor-Car Exhibition are crowding into the Berner's Hall, which has two main entrances, and it is evident that this section of the Exhibition will, by the variety of its exhibits, prove a popular branch of the show.

AT the Begbie Manufacturing Company's general meeting, on the 26th ult., a dividend was declared for the past year of ten per cent. The chairman informed the meeting that the increase of business for the first months of the new year was considerably in advance of the previous twelvemonth, and that there was every prospect of a very prosperous year.

SEVERAL firms of cycle dealers and others in Guernsey have recently added the sale of motor-cars to their businesses. Among these is Mr. T. G. Wyatt, whose engineering works are at North Clifton, in the island. To do this satisfactorily he has obtained new premises in New Street, Guernsey, for a showroom, level with the street, with workshops behind, and store-rooms above,

Digitized by Google

HERE AND THERE.

THE London United Motor Company, Limited, has been registered with a capital of £1,000.

THE Manchester Motor Supply Company are now installed in their new premises at 18, Oxford Street, Manchester.

THE new 15-20-h.p. four-cylinder Brooke car will be exhibited for the first time at the Agricultural Hall Show.

PROFESSOR HUGH GALT will read a paper on "The Medical Aspects of Motoring," at a meeting of the Western section of the Scottish Automobile Club on Monday.

MESSRS. A. CONSTABLE AND COMPANY, LIMITED, are the publishers of a new work on Entropy by Mr. James Swinburne. This deals with thermodynamics from an engineer's standpoint.

THE South Wales and Monmouthshire Automobile Club contemplates opening a club garage at Cardiff. The Motor Garage Company have lately opened a garage in Queen Street, in that town.

THE Napier Motor Company has been incorporated in Boston under Massachusetts laws with a nominal capital of £2,000, but with the right to increase to £200,000. The new company acquires the agency for Napier cars in the United States, Mexico and Canada.

THE problem of conveniently and expeditiously charging ignition cells is one which is continually exercising the mind of every motorist. In nearly every town of any importance it is now possible to obtain a supply of current, but, owing to its being at a comparatively high pressure, considerable trouble is involved before it can be made available for charging. Messrs. Everett, Edgcumbe and

Co. have lately brought out a charging set known as the "Everright," which may be carried in the tool box, by means of which current can be instantly obtained from any electric light fitting and passed into the accumulators, with the certainty that it does not exceed the correct amount, and, also, that it is flowing in the right direction. The set is made up in three distinct forms:—Type A (see illustration) consisting of two lamp-holders, current direction indicator, adapter and ammeter reading to 2½ or 5 amperes, as preferred, complete with flexible connections, etc., in walnut case, with carrying handle for travelling; type B, similar to this, with current direction indicator, etc., but without ammeter; and type C, similar to type B, only without the case. These little sets, which are neatly and compactly constructed, are, we hear, becoming very popular, and will certainly be found a great boon to all motorists employing accumulators.

THE Medway Motor and Engineering Company, Limited, has been registered with a capital of £2,000 to acquire the business of motor and cycle manufacturers and general engineers carried on by Messrs. A. Wilson and E. T. Middlemiss at 56, High Street, Chatham, as the Chatham Machine Company.

MESSRS. COXETER AND SONS, LIMITED, of Abingdon-on-Thames, on Tuesday opened new motor works and garage in Pembroke Street, St. Clement's, Oxford. A competent staff of mechanics will be available for repairs of all kinds, while the garage has accommodation for fifty cars, with facilities for charging batteries.

MESSRS. J. E. GIBBS, of Thomas Street, York, have facilities for the repair of motor-cars.

THE Norfolk Automobile Club are sending a strong protest to the Local Government Board in reference to the county council's proposed ten-mile limit in certain Norfolk towns.

FOR cleaning metal work the Rocket liquid plate and metal polish is becoming favourably known. Being guaranteed free from acid and uninflammable, it will be of service to motorists.

AN ILLUSTRATED catalogue of electric welding machines and apparatus comes from the Electric Welding Co., Limited. They are the owners of the Thomson process of electric welding, which has been applied with great success to the automobile industry, particularly with reference to the welding of such parts as hubs, flanges, gear boxes, tubular framing, steering gear, axles, cam shafts, crank shafts, and such like.

TURNER'S Motor Manufacturing Company, Limited, inform us that in future they intend to call the Miesse car, of which they are the sole manufacturers in this country, the "Turner-Miesse." The name "Miesse" by itself gives many people the idea that it is a foreign-built car, whereas it is of English workmanship throughout, the engines and everything else being made entirely in the company's works in Wolverhampton.

THE Kelecom Motors, Limited, is the title of a company registered with a capital of £10,000, to adopt an agreement with Mr. E. J. Willis for the acquisition of the business of a manufacturer of and dealer in motors, motor-cars and their accessories, now carried on by him at 79, Wells Street, Oxford Street, W., as the Ormonde Motor and Cycle Company, and to carry on the said business. The first directors are Messrs. R. Willis and A. Goodwin.

THE Tisbury (Wilts) Urban District Council sought to have motor-cars prohibited on the roads under its jurisdiction, on the ground of their insufficient width for such traffic. But by the Highways Act of 1835 justices of the peace may order roads of inadequate width to be widened to a breadth of thirty feet at the expense of the local ratepayers. A Tisbury motorist has accordingly requested two justices to inspect the roads in question, with the result that the District Council has been instructed to widen them.

CONTINUING their series of Little Guides to English Counties, Messrs. Methuen and Company have issued a handbook to Suffolk arranged on the alphabetical plan which has proved so convenient for travellers wishing to post themselves up with the history and sights of the places to which they journey. Mr. W. A. Dutt is responsible for the letterpress and Mr. J. Wylie for the illustrations in the new volume. Suffolk is an interesting though not particularly well-known county of East Anglia; and the motorist with Messrs. Methuen and Company's guide in his wallet will appreciate its pleasant places and picturesque villages.

THE latest fire-extinguishing appliance is the new petrol motor-fire engine just built by Messrs. Merryweather and Sons for Baron A. de Rothschild. It is not only driven along the road by a petrol motor, but the same power is used, on arrival at the fire, to drive the pumps. The vehicle has a steel frame, on which are mounted a 30-horse power four-cylinder petrol engine, a 300 gallon "Hatfield" pump, and a large hose and tool-box, forming seats for driver and firemen. The whole is mounted on steel springs and artillery wheels, and solid rubber tyres. The engine is placed in front, and drives, through a pedal-actuated cone clutch and Panhard type gear box, a countershaft, from which the rear road wheels are driven by means of side chains. A second shaft is fitted, with positive clutch to the engine and arranged to drive the pump at the rear by means of a raw hide pinion and spur wheel. The pump suction inlet and two delivery outlets with valves are provided at the rear, a footplate being provided, so that two men can ride behind. On top of the hose-box is fitted the petrol tank, and the ignition arrangements are in duplicate, accumulator and coil as well as a high-speed magneto machine being fitted.

Digitized by Google

MR. LIONEL ROTHSCHILD has obtained delivery of his 40-h.p. Mercedes.

THE Hyde Rubber Works, Limited, and the Hyde Rubber Company are two distinct concerns.

A PUBLIC service of motor-cars has recently been established between Mykobing and Nysted, Sweden.

THE Ladies' Automobile Club of Great Britain and Ireland, Limited, has been registered with a capital of £100, in £1 shares.

THE next meeting of the General Committee of the Motor Union will be held at 119, Piccadilly, London, W., on Monday the 7th inst.

JUST now there seems to be a general advance in Wales so far as public desire for motor vehicles is concerned, and the Pontypool District Council is asking the Great Western Railway to run a motor coach between Pontypool and Aberbeeg.

THE Imperial Tyre and Rubber Co., Limited, are placing on the market an inner tube repair outfit for vulcanising patches to tubes by means of an air vulcanising fluid of their own preparation.

BORIS SARAFOFF, the young Bulgarian chief of the insurrectionary movement in Macedonia, is reported to have ordered a light, strongly-built motor-car for next season's campaign, to enable him to move about rapidly on the rough roads of the plain.

THE Lion Motor and Cycle Company, Limited, has been registered with a capital of £2,000 to acquire the business carried on by Mrs. Ann M. Pinnell at 189, London Road, South Lowestoft, as the Lion Cycle Company, with certain patents relating to an improved motor and cycle brake.

THE Birmingham coroner has conducted an inquest concerning the death of a coach trimmer, who had been engaged at a motor-car works. About a fortnight ago, while padding the back of a car, he drove a tin tack into the finger nail of the right hand. A fellow-workman described the wound as the prick of the point of a tack, and it bled a little. Deceased held the finger in hot water, and a day or two later it festered. He did not tie it up and made light of the occurrence. Shortly after, however, deceased's arm became swollen, blood-poisoning intervened, and death ensued as the result of pyæmia.

THE following is from the "Morning Post":—There will be only one more important motor-car show before the season begins. Over three hundred exhibitors have taken space for stands at the exhibition which will be opened at the Agricultural Hall under the auspices of the Automobile Club of Great Britain and Ireland. The display will be so numerous that Berner's Hall will be utilised for the first time in the history of industrial exhibitions at Islington. Not the least notable feature of the show will be several British-made cars that were not completed in time for the exhibition at Sydenham. The display of heavy vehicles in the minor hall will be particularly representative. Some new types of municipal vans will make a first appearance, and the Beadle airship will also be on view.

"HIGHWAYS and Bye-ways" in Sussex is the title of a new volume by Mr. E. V. Lucas, which has been published by Messrs. Macmillan and Company, Limited. This is one of a series which already includes Yorkshire, Devon, North Wales, the Lake District, and other touring districts beloved by those who tour. In writing on Sussex Mr. Lucas has largely determined his order of progress by the lines of railway. Entering the county at Midhurst, he has gone in a zig-zag course across to the east by way of Chichester, Arundel, Petworth, Horsham, Brighton, Cuckfield, Lewes, Eastbourne, Hastings, Rye and Tunbridge Wells, emerging on the borders of Ashdown Forest. This is not the route the motorist would take in seeing Sussex, but the capital index at the end of the volume, together with the map, will compensate for deviations from the road. The excellent illustrations by Mr. F. L. Griggs add to the pleasure of reading a volume in which ancient lore is admirably combined with picturesque descriptions of the present prospect.

CORRESPONDENCE.

PETROL FOR COOLING.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—If petrol does not readily freeze, and is not easily heated, would it not be better than water for the tank?

I should like to hear if anyone has tried it, or if its use would be dangerous for cooling purposes.—Yours truly,

OVERHEATED

BENZ v. LIGHT CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In answer to "G. L. B.," I think he is right in his surmise respecting the "geared Benz," especially the 7-h.p. There is no doubt that there has been considerable confusion made in respect to the ordinary and the "geared" Benz, to the discredit of the latter.

Having driven the 7-h.p. geared and several makes of light cars, I have never found one so efficient as the 7-h.p. geared Benz. It is fast enough for country roads, and will do over 30 miles per hour, whilst, on the other hand, it will surmount any hill with its full load.

Being very easily driven and controlled, also as simple as a car can be, I know some of your readers will readily condemn it because it has belt transmission. But I believe it has many points in its favour, and should give no trouble with proper attention. There are, no doubt, several other "Benzites" who can testify to the good qualities of the "geared Benz."—Yours truly,

SOLID TYRE.

WOOD PAVING.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I note still another case of side slip due to the greasy condition of wood paved roads. A motor-car essayed to go into a draper's shop in Brighton on Sunday. It seems a pity that those in charge should treat these the same as ordinary macadamised roads. The original idea was the same as with asphalte, viz., to produce a surface which could be easily washed down and kept clean. I wonder how often the London road at Brighton has been subjected to the ordeal of a bath. I have frequently found it exceedingly slimy and treacherous.—Yours truly,

A.

LOSS OF POWER.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Owners of 3½-h.p. Benz cars should look to the size of their valves. These cars first came out, I think, with valves about 1 in. in diameter. This was found to be too small, and I think the later pattern had them increased in size. I owned one of these cars for nearly a year, and the previous owner had fitted inlet and exhaust valves 1¼ inch diameter. This car would mount a gradient of 1 in 25 on the top speed, and 1 in 12 on second, and anything, I believe, on the crypto; but it occasionally used to lose power, and I always found the causes to be as follows:—First, auxiliary air valve out of order. The spring of this valve should be almost the same tension as the inlet valve spring, but very slightly stronger, so that the inlet valve opens a little more than the auxiliary. This valve often gets covered with mud or dust, and is either choked or leaks, in which case compression is weakened. Second, the petrol in the Benz carburettor gets stale and weak, especially after standing an hour or so with engine stopped. Third, the fibre wheel in the half-time gear gets worn, and the exhaust valve opens too late. If this car is fitted with 1¼ inch valves, and the auxiliary inlet is properly adjusted and tight, it will take two people up a very fair hill on its top speed. I am certain that many small cars are now being blamed for loss of power, while the real cause is the state of the roads. Owing to the long-continued rain and lack of sunshine, gravel roads have become thoroughly sodden and water-soaked; though, after a day's dry weather, the surface may be free of mud, the foundation is still soft, and a large proportion of power is lost, much more than one would believe possible.—Yours truly,

CHAS. PERCY DEAN.

CARS FOR MEDICAL MEN.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—With reference to "Motoring Medico's" letter in your last issue, asking why the leading makers do not build cars to drive with belts, the reason is that foreign motor manufacturers are, to a certain extent, compelled to follow the fashion, and it would be a difficult matter for an agent to find buyers at the present time for belt-driven cars. Although I am no longer connected with the company selling the Benz cars, I know from long experience that a small car up to 10-h.p., driven with a straight belt (not crossed), gives no trouble whatever—in fact, I have driven quite 5,000 miles without ever touching the belt. With big cars, however, the belt sometimes does give trouble, unless one has an extraordinarily good belt. I think the magnetic clutch must be most satisfactory; as it is arranged, if the pedal of the clutch is worked very slowly, the clutch will slip a little, until the full force of the magnetism is on, which has about the same effect as a belt-driven car. There is no sudden shock on the gear.—Yours truly,

H. HEWETSON.

Digitized by Google

MAGNETO AND ACCUMULATOR IGNITION.

To the Editor of *The Motor-Car Journal.*

Sir,—May I ask some one who is well versed in the subject to give me a few hints upon ignition, through your valuable medium, which I read with interest every week. I have a car with horizontal engine and magneto ignition, but find great difficulty in starting. Can I fit an accumulator and De Dion induction coil and wire up to the same make and break which is in the cylinder, without any sparking plug, or shall I require a trembling coil? The contact is broken by a tappet which works against a cam on the end of 2 to 1 shaft. There is automatic water circulation for cooling; shall I get much advantage by inserting a pump? The ignition takes place just before the end of the compression stroke; should I not get more power if the explosion occurred at the beginning of the forward stroke? Thanking you in anticipation,—Yours truly,

A Gloucestershire Novice.

[For "A Gloucestershire Novice" to fit his engine with electric ignition by means of coil and accumulator, it will be necessary for him to do away entirely with his present mechanical device, which he uses with magneto, and in place fit a sparking plug. It will also be essential to fit a contact breaker and trembler coil in preference to non-trembler. If this form of ignition is fitted, the spark can be made either early or late, this by means of moving the contact breaker backward or forward. The proper position for the piston in the cylinder when the spark is retarded is about one inch down the stroke, but when advanced the engine increases in speed and the spark occurs earlier. This, of course, appears to have the tendency to drive the engine backwards, when the position of piston is ascertained in relation to time of spark; but when the piston speed is taken into consideration, together with the time it takes for the spark to form at the plug, the cause is easily explained. The power of the explosion actually is exerted on the piston at about the dead centre. With regard to the water circulation, this we should leave, if every satisfaction is obtained from the present system.]

MORE TYRE QUERIES.

To the Editor of *The Motor-Car Journal.*

Sir,—May I ask the scientific readers of the *Journal* why a solid tyre on a motor-car, though admittedly slower on the level, is faster than a pneumatic up a hill? I am only a cycle rider, and well know that in any degree of inflation, and under any road conditions, a pneumatic-tyred cycle is much faster up hill or down than a solid, yet at the Crystal Palace I was told by a firm of tyre makers that a solid tyre is faster up an incline, and that is because a pneumatic tyre, by reason of its flabby walls at the point of contact with the road, allows the wheel to "float" about, and so lose the power in transmission, whereas a solid tyre loses nothing in this manner. I absorbed this shock, and was quite prepared to hear that the pressure of air per square inch in a car tyre is not increased, however much extra weight is put on board.

Still another curious thing was told me by the same people about a new pneumatic tyre now being much discussed. The finest theoretical and expert knowledge they declare teaches them that a nail will very quickly puncture this tyre; the nail strikes the hard resisting cord, and, instead of cutting it, is diverted to the side, and with a rush passes between one cord and the next, thus puncturing the inner tube. My own reasoning is different to this, as I should contend that at the flat of the tyre, at the contact with the road, the tangential cords which are already touching would take still closer order, and have a tendency to pinch out the nail which tried to slip between them. However, I should be glad to hear the opinions of others on the above matter, as my convictions are rather unsettled.—Yours truly,

G. R. F.

QUERY *RE* NEW GEAR DRIVE.

To the Editor of *The Motor-Car Journal.*

Sir,—In your show report, in the *Journal* of February 20th, you gave a description of the "Dennis" silent worm drive to live axle. One of your contemporaries also recently described a car (Hitchon-Weller) which is said to possess a similar arrangement. This information, though very interesting, leaves us wondering what happens when the clutch is disengaged while the car is running. It seems clear that one could not "coast" unless the back axle were fitted with a free-wheel device of some sort, in which case reversing seems impossible. Trusting you will find space for this, as I know I am not the only one who would like information on this point.—Yours truly,

Live Axle.

STORAGE OF PETROL.

To the Editor of *The Motor-Car Journal.*

Sir,—Motor-cyclists will be interested to know that petrol may be stored by any person in quantities up to three gallons, so long as it is contained in separate one-pint vessels. (See *Motor-Car Journal*, April 18th, 1903, p. 148.) If larger quantities are kept, and are stored within 20 ft. of a woodstack or building, is it necessary to give notice and obtain permission to store it? In some anti-motor districts this permission is withheld if possible. The motorist is then entirely dependent on the capacity of the tank on his motor-car, and this tank most likely holds less than two gallons; he is, therefore, obliged to purchase his petrol in very small quantities, and at increased price. By using the one-pint tins he might buy a can of petrol and fill up his tank and put the remainder in the tins till it was wanted.—Yours truly,

B.W. 12.

DRIVERS.

To the Editor of *The Motor-Car Journal.*

Sir,—Having read the correspondence in your *Journal re* the scarcity of good mechanic-drivers, and being a mechanic and driver, capable of repairs of all kinds, I was hoping to see some feasible scheme suggested whereby really capable drivers and mechanics (not the driving school certificated so-called mechanic-driver) could be brought into touch with gentlemen requiring capable men, and who were willing to pay a good mechanic's wage. There are plenty of good men who would be glad to see a strict test instituted as to the capabilities as driver and repairer, the passing of which would entitle them to a certificate, which certificate would then be of some value, not as certificates are obtained now, by the payment of from £2 to £5 and a week's tuition at some driving school.—Yours truly,

Mechanic.

[We would ask correspondents on this subject to make their letters as concise as possible, and also to avoid the repetition of ideas which have appeared in previous correspondence. Otherwise we cannot find space for one-tenth of the interesting letters that we continue to receive on this subject.]

THE CLUB COMMITTEE.

To the Editor of *The Motor-Car Journal.*

Sir,—With reference to the resolutions that I will propose at the forthcoming general meeting of the Automobile Club, I should be obliged if such gentlemen who are in agreement with my "resolutions" would send me their proxies to 12A, George Street, Hanover Square, London, W., same being made out as follows:—

I.....of....., being a member of the Automobile Club of Great Britain and Ireland, do hereby appoint the Right Honourable the Earl of Shrewsbury and Talbot, or him failing, the Right Honourable Lord Westbury as my proxy to vote for me at the meeting of the Club to be held on the 10th March, 1904, at the Institution of Mechanical Engineers, Storey's Gate, Westminster, London, S.W., and at any adjournment of the meeting.

Dated the.....day of March, 1904.

Your obedient servant,

Shrewsbury and Talbot.

THE COST OF REPAIRS.

To the Editor of *The Motor-Car Journal.*

Sir,—The further letter from "Chirurgeon" puts a different complexion on his case. Certainly, if the same jobs had to be done two or three times over, "Chirurgeon" is—to say the least of it—unfortunate in his choice of a repairer. Of course, I took the item he gave to be work—necessary work done, and it is decidedly difficult to understand how £16 worth of repairs to a cylinder can be necessary. To sum up this case, we have an 8-h.p. Progress car costing £270, which in eighteen months has cost £2 12s. through accident, but in the last three or four months has cost nearly £100 for repairs *not* caused by accident. It is difficult to believe that the car is so thoroughly bad. In motor repairing it often happens that a lot of work has to be done, for which there is very little to show, as "Chirurgeon" will no doubt understand, and for this reason a repairer's just charge is often considered excessive. I am sorry that there should be many incompetent motor repairers, and should welcome any scheme for registering the competent ones. Could not a list of really competent motor-repairing firms be compiled? Readers could then write and ask for the name of competent firm in any district. When complaints were received, if found to be true, the offending firm could be struck off the list. I throw out this suggestion, and perhaps other readers will criticise the idea.—Yours truly,

Francois.

MOTOR GARAGE FOR HOTEL.

To the Editor of *The Motor-Car Journal.*

Sir,—I am desirous of erecting a motor garage for an hotel to hold from four to six motor-cars. Will any of your readers kindly say what would be about the proper dimensions, and if there are any special features they can recommend?—Yours truly,

R. Kay.

[This is an interesting subject, and motorists are invited not only to forward suggestions for hotel proprietors desiring to cater for their wants, but also their experiences in housing cars when away from home.

Experiences with Paraffin Carburettors.—Lieut. Windham has sent us a letter in reply to one from Mr. D. G. Smith in our last issue. Both sides have had a hearing, however, and we regret that pressure on our space will not permit us to publish further letters on the point.

The Crystal Palace Automobile Show.

[Concluding Notice.]

Below we conclude our report of the recent Show. Motoristsare now looking forward to the Agricultural Hall Exhibition, at which several new models will be shown for the first time. Not a few makers have also waited till the March event to bring new accessories, etc., to the notice of the trade and public.

PETROL CARS.

The Motor Manufacturing Company, Limited, furnished one of the *clous* of the exhibition, viz., the 25-h.p. Saloon car, of which an illustration was given in our issue of December 19th last. The body, which was designed and built at the Coventry Works, is of the most sumptuous description. There are four corner seats inside, consisting of comfortably upholstered revolving chairs. Folding tables, drawers, and lockers are among other fitments, in addition to a barometer, thermometer, and clock. The occupants can communicate with the driver by speaking tube, while in addition there is an instruction dial, by means of which, by moving a handle the wishes of the owner are transmitted to the driver, somewhat on the same lines as a captain communicates orders to the engine-room of a steamer. Specimens of the M.M.C. 20-h.p., 10-h.p., and 8-h.p. cars were also displayed, a noticeable improvement in these being the provision of an iris throttle valve. This is controlled by the governor, and works on similar lines to the well-known iris shutter in photographic cameras. A new addition to the popular 8-h.p. M.M.C. cars is a mechanically-operated inlet valve and a governor, as a result of which the running of this vehicle has been made much quieter. Several new designs of bodies were shown fitted to the 8-h.p. *chassis*, these including a two-seated hansom cab, a landaulette, and a mail phaeton. A 20-h.p. car with Roi des Belges body, having entrance at the side, was another vehicle to which reference may be made. It was pleasing to find that the M.M.C. concern had two *chassis* on view, one of the 20-h.p. type and one of the 8-h.p. Both were excellent specimens, and attracted much attention on the part of visitors. In addition, examples of the 20-h.p. motor with mechanically-operated inlet valves, the 10-h.p. double-cylinder engine, and a full range of the M.M.C. cycle-motors had a prominent position on the stand.

In addition to examples of their 3½-n.p, 9-h.p., and 15-h.p. cars, the New Orleans Motor Company, Limited, had on view a new 12-h.p. four-cylinder car, which attracted much attention. The engine has four separate cylinders, 85 mm. diameter by 110 mm. bore, and runs at a norma speed of 900 revolutions per minute. It is carried on the main frame, which is constructed of wood and steel. The throttle on the admission pipe is controlled both by its own pedal and also by a clutch pedal, so that when the clutch is taken out the engine is automatically slowed down. One o the novel features of the car is the clutch; this is of the internal cone variety, with the difference that the cone is in two halves and bolted to a driving plate, from which each may be readily removed by detaching three bolts. Three speeds forward and a reverse are available, the power being transmitted to the rear live axle through a cardan shaft and bevel gear. On the top speed the drive is direct, neither the side shaft nor any of its pinions rotating. The engine clutch and gear box are protected from below by a shield of aluminium. The New Orleans cars have long had a reputation for quiet running. and the new 12-h.p. model should be no exception.

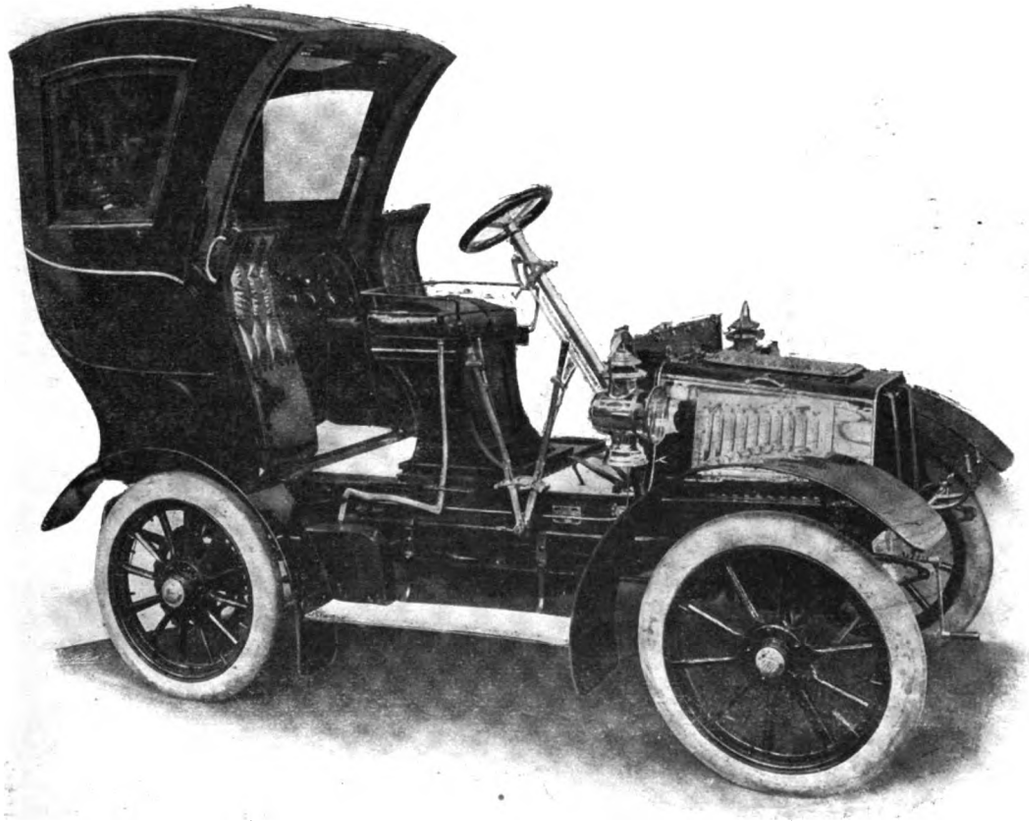

Fig. 67.—The M.M.C. 8-h.p. Hansom.

The latest models of the Benz Parsifal cars were displayed by Messrs. Hewetsons, Limited, and we must first of all remark as to the evident progress this firm has made in construction in recent times. For 1904 four types are being made—8-h.p. single cylinder, 12-h.p. two cylinders, and 22-h.p. and 35-h.p. four cylinders, examples of the first three being on view. The latest productions follow the standard lines, having the engine set in the front part of a pressed-steel frame. The engines have mechanically-operated inlet valves and an automatic carburettor. The smaller type has the usual coil and accumulator ignition, while the large sizes have magneto and high-tension ignition, as well as a governor acting on the inlet valves in such a way as to vary their lift. The clutch is also of the metal-to-metal type, and runs in oil. The 35-h.p. car has side chain transmission, but in others the power is conveyed to a rear live axle through a cardan shaft and bevel gearing.

Digitized by Google

Messrs. Coles and Wyss, the new title of the firm of Messrs. E. J Coles and Co., exhibited a new and interesting vehicle of Swiss construction. As will be seen from Fig. 68, the frame is of tubular construction; the single-cylinder engine is 110 mm. diameter by 120 mm. stroke, and develops 8-h.p. The inlet valve is mechanically operated, and is provided with a variable lift device, controlled both by a hand lever and by the foot. A special form of carburettor is employed, having an inlet to permit the engine to take in an additional supply of air when running at high speeds. Three speeds forward and a reverse are provided, the drive being by cardan shaft and bevel gear on to a live axle. Altogether, the new Coles-Wyss car contains many good points, and is worthy of the careful examination of those seeking a vehicle at a relatively low price. A more powerful car on similar lines, fitted with a two-cylinder 9-11-h.p. engine, is also being introduced.

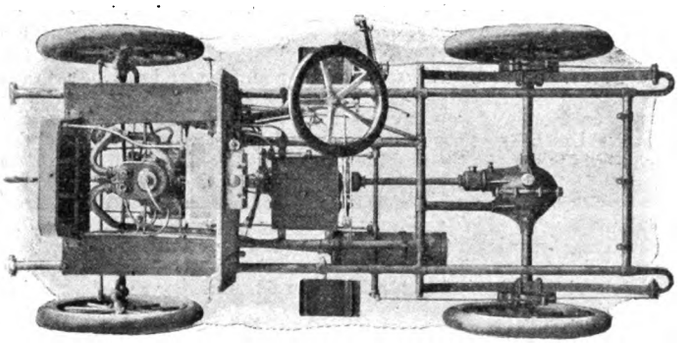

Fig. 68.—Chassis of Coles-Wyss 8-h.p. Car.

Messrs. H. M. Hobson, Limited, had a varied exhibit, prominent among which was the 24-30-h.p. four-cylinder *chassis* constructed by La Societé La Locomotrice of Liege, under licence from the Rochet-Schneider Company. While it is unnecessary to describe the details at length, we may mention that the Belgian production compares most favourably with that of the Lyons concern, and that it attracted considerable attention at the Show. Fig. 70 illustrates the 16-h.p. "Dasse" car shown by this company. The motive power is supplied by a two-cylinder engine with mechanically-operated inlet valves. The water circulating pump is attached to the cylinders and is driven by the same belt as operates the fan behind the special tubular radiator. The car is of the gear-driven live axle type, and has three speeds forward and a reverse. Peugeot 2½-h.p. motor-bicycles, the "Perfecta" non-skidding band, and the "Pognon" sparking plug were other exhibits of interest at this stand.

In addition to a large 20-24-h.p. four-cylinder car, the Velox Motor Manufacturing Company had on view a little 5-h.p. two-seated car. This is chain-driven throughout, and has two speeds and a reverse. One was fitted with a van body capable of carrying loads up to 2 cwt.

The Brouhot Motor Company of Great Britain, Limited, a new concern formed to introduce the Brouhot cars into this country, exhibited a *chassis* and complete tonneau of this type. The cars are made in size ranging from 12 to 40-h.p. Dealing with the 12-14-h.p. car exhibited, the frame is being made sufficiently large to accommodate a body having side entrances. This is fitted with an engine, the four cylinders of which are cast in two pairs, the cylinders being 90 mm. diameter by 100 mm. stroke, the normal speed being 1,000 revolutions per minute. All the valves, both inlet and exhaust, are mechanically actuated off one cam shaft. The carburettor is Messrs. Brouhot's own design, and provides for the automatic regulation of the air in order to give the correct mixture at any or all speeds. The jet is also so arranged that it can instantly be taken out for cleaning purposes. Pump circulation is adopted in conjunction with a framed ribbed pipe cooler and tank, through which a current of air is drawn by a belt-driven fan. The transmission is by side chains, the drive on the top speed being direct. The governor is adapted to act on a throttle valve, which when entirely closed opens a second valve to allow the engine to draw in cold air. An ingenious form of friction clutch is employed to connect the engine with the gear-box. It consists of a steel band, the outer surface of which is lined with camel-hair belting. The band itself is so arranged that it can be readily detached; it is expanded within the fly-wheel by means of two toggle levers. The countershaft brake is water-cooled, while those in drums on the rear wheels are practically identical in form and action with the clutch. To ensure proper lubrication of the engine each pair of cylinders have their own base chamber. There are other points of interest in the Brouhot cars to which we may return on a later occasion.

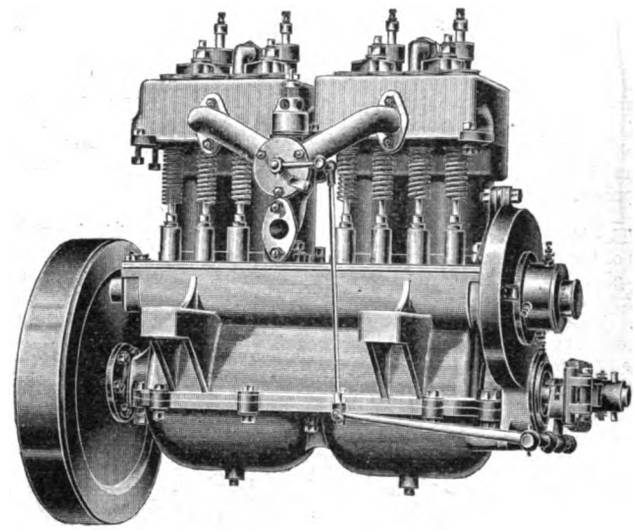

Fig. 69.—The Brouhot Four-Cylinder Engine.

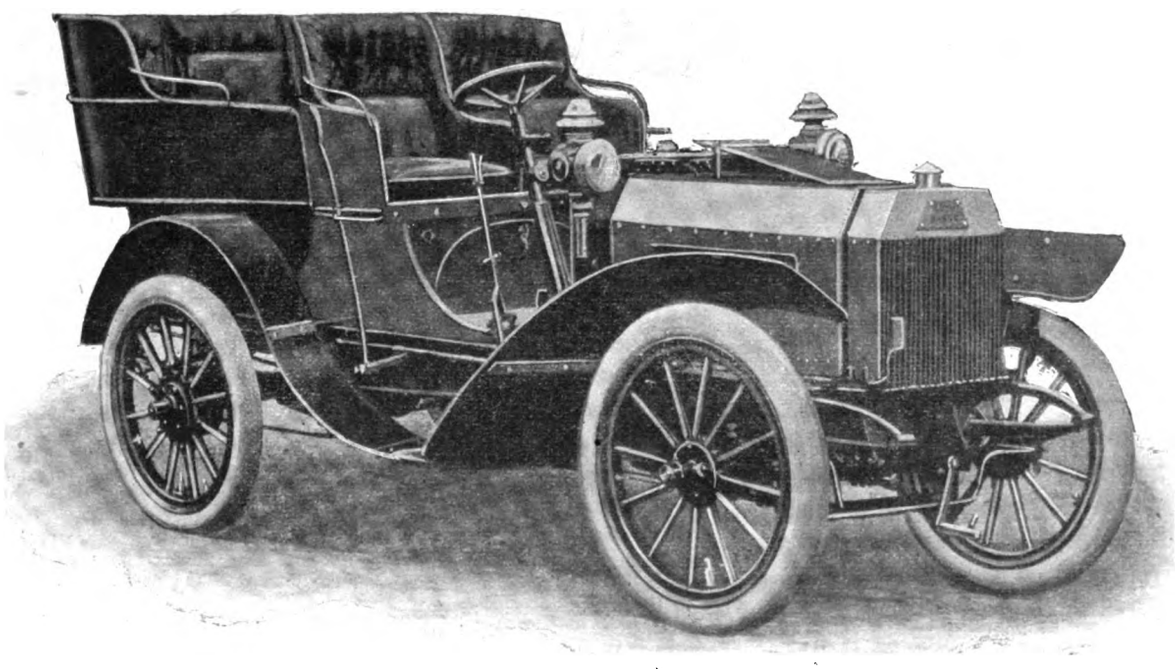

Fig. 70.—The Dasse 16-h.p. Car.

Digitized by Google

The Firefly Motor Company is devoting considerable attention to motor delivery vans, and had several examples of these on view. So far as the *chassis* is concerned, these follow the usual lines of gear-driven cars, the gear and various parts, however, having been designed for the special work, and also to enable the vehicles to run on solid tyres. A useful type for drapers is a 6½-h.p. van to carry loads up to 6 cwt. at speeds ranging to fifteen miles per hour. The van to carry 10 cwt. is provided with a 8-9-h.p. engine, while that to carry 25 cwt. has a double-cylinder

Fig. 71.—The "Firefly" 25 cwt. Delivery Van.

motor. The transmission on this vehicle is on the lines of that adopted on the Milnes-Daimler and Chenard-Walcker vehicles—that is to say, the cardan shaft, instead of driving by bevel gear on to a live axle, drives a differential shaft parallel with the fixed axle. The shaft carries at its ends pinions which mesh with internally-toothed wheels attached to the rear road wheels. Either van or open-sided bodies can be fitted to the *chassis*, rendering them suitable for all classes of work. In this connection we may refer to a new device known as a portable "Auto-Elevator" the Firefly Company are introducing. This is arranged to be carried on the vehicle, and is intended for raising heavy goods (up to 15 cwt.) from the ground level to the floor of the vehicle, and consists of a platform raised or lowered by means of a screw or chain worked by the motor while the van is at rest. When not in use the auto-elevator may be folded up and slid underneath the body of the van. Among the pleasure cars exhibited by this company we noticed a 10-h.p. gear-driven vehicle, fitted with a special hansom cab body, with separate seat for the driver, and ample room for luggage.

The exhibit of the Brush Electrical Engineering Company, Limited, comprised examples of the 10-h.p., 14-h.p. and 18-h.p. cars, all chain-driven vehicles. The latter is a new type, having a four-cylinder engine with mechanically-operated inlet valves. The clutch and brake pedals, as well as the hand-brake lever, are all connected up to the throttle valve on the inlet valve. The engine is fitted with Doyle's special valve in connection with the carburettor, an ingenious device, performing three distinct functions, namely, it scavenges the cylinders with cold air during the governing, proportions the mixture at all speeds of the engine, and admits cold air when coasting down hill. Other features of the car are the special ignition wire terminals and a self-centreing clutch between the engine and gear box. The Brush Company have also taken up the construction of public-service vehicles, and had on view a 30-b.h.p. double-deck 'bus to seat thirty passengers. The motive power is supplied by a four-cylinder engine, and is transmitted through a clutch to a change speed gear, the pinions of which are always in mesh, the requisite pair being made to transmit the power by means of clutches. The Brush Company also had on view a light two-seated car known as the Brushmobile (Fig. 72); it is made in both 5-h.p. and 6-h.p. sizes, and is fitted with a single-cylinder horizontal engine, the transmission, steering and general control being on very similar lines to that adopted in the Vauxhall car.

For the 1904 season Les Automobiles Clement, represented in this country by Mr. E. H. Lancaster, are making five types of cars—6½-h.p. single cylinder, 9-11-h.p. double-cylinder, and 10-h.p., 12-16-h.p., and 20-h.p. four cylinder, the largest size having a chain drive. In the others the cardan shaft system of transmission is adopted. The engines have mechanical inlet valves and a special carburettor, in which the automatic regulation of the air is obtained in an exceedingly simple manner, no springs or diaphragm being employed. Special attention has been paid to the brakes, a simple and useful spring device being provided to keep the band off the drum when the brake is not in use. The cars are being made with frames sufficiently long to take bodies with entrance to the rear seats at the sides, some excellent examples of which were on view.

In the "Ludgate" car Mr. J. F. Bentley has a low-priced vehicle, which, for those who do not appreciate the fore-carriage, will be found serviceable. It has a 3½-h.p. water-cooled engine with chain transmission direct from the gear box to the back axle. Two passengers can be carried at a speed well up to the present legal limit.

A 6-h.p. Planet car on the stand of the Automobile Engineering Company provided something of interest for those on the look-out for a popularly-priced car, and the fact that this company will be showing this and other cars fitted with engines of 9-h.p., 12-h.p., and 24-h.p., at the forthcoming exhibition should also be mentioned. The model shown was a two-seated vehicle with a single-cylinder engine having mechanically-operated valves, automatic carburettor, and transmission by a cardan shaft to the live axle. On top speed the drive is direct. Fitted with artillery wheels, pneumatic tyres, and bucket seats, the 6-h.p. Planet car should have considerable vogue during the coming season.

A good display was made by the Imperial Motor Company of 6-h.p., 12-h.p., and 16–20-h.p. cars. These cars are distinguished by great efficiency and are fitted with bodies of admirable finish.

In a side court the Mobile Motor and Engineering Company, Ltd., had a full display of their vehicles, including those of 12–14 and 14–16-h.p., as well as a small 6-h.p. Mobile car of good appearance and moderate price. The larger size cars are fitted with Prunel or De Dion engines. In the 12–14-h.p. silent Mobile car is a double-cylinder Aster engine of the slow running type, making 1,000 revolutions per minute on top speed. The carburettor is a Longuemare, electrical ignition and wipe contact being also fitted. The cooling is effected by a Mercedes pattern radiator. Three speeds and reverse are provided on a single lever.

Mr. Doulas S. Cox made a feature of the Hulbert-Bramley motor-bicycle and the new model of the Cottereau car, the type shown being one of the 12–16-h.p., and described in our report of the Paris *Salon*.

In addition to their automobiles, the General Motor-Car Company exhibited the Fouillaron change-speed gear, by means of which a gradual change of speed can be effected. In this device the driving pulley is keyed to the main shaft, the driven pulley being actuated by a specially-designed steel chain. A cardan shaft transmits the power to the live back axle. To get the reverse it is only necessary to press a pedal placed conveniently for the driver. A 6½-h.p. car with an Aster engine specially designed for the use of doctors was on view, as also a mail van such as the company use in their contract with the G.P.O., and a 30–32-h.p. car with a canopy. This canopy has some special features of construction, being made so that the front window slides in the uprights until it can be swung on the under side of the roof, clear of the steering wheel. A new form of spiral radiator is also being brought out by the General Motor-Car

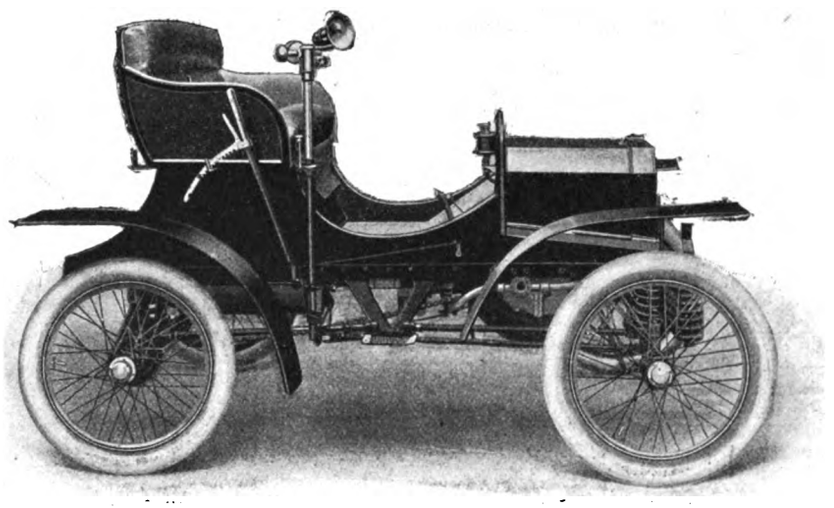

Fig. 72.—The 6-h.p. Brushmobile.

Limited, whose display excited considerable interest during the exhibition.

Mr. Montague Atkinson, who has secured the London agency for the Spyker cars, had on view two excellent specimens of the 24-h.p. four-cylinder cars of this type. These cars are of Dutch construction, and some reference to their details was given in connection with the report of the stand of the Elsworth Automobile Company.

STEAM VEHICLES.

It is satisfactory to find that attention is still being paid to the steam car, and it is with satisfaction that we record another addition to the list of British-built steam cars in the "Keenelet," built and exhibited by KEENE'S AUTOMOBILE WORKS, LIMITED. It is of 14-h.p., and has the engine set in the front, and the generator in the rear of a steel frame. The generator consists of, approximately, 300 feet of steel coils, arranged in ten layers; each layer slides in a tray, and can be withdrawn without disturbing any of the others; each set of coils being joined to the next by a special clamp joint, so arranged that it can be undone, in case of necessity, in about thirty seconds. The fire, which uses common petroleum, is silent in action, and is stated to be absolutely reliable so long as the single

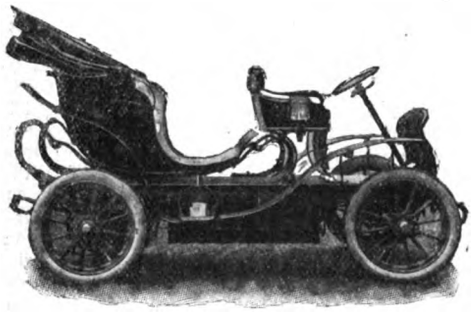

Fig. 73.—The Electromobile Co.'s C.-Spring Victoria. (See page 988 ante).

jet is kept reasonably clean; this jet is very accessible, and can be cleaned through at any time in about one minute. Close attention has been given to the cooling of the seats; there is a space of about 8 in. beneath the top of the funnel and the bottom of the seat; over this a volume of slightly compressed air is constantly travelling, so that the seats never become hot even after the longest run. The fire is fitted with a pilot light, so arranged that the car may be left standing for twenty-four hours, if necessary, and be ready for use at any time. The engine is of the single vertical cylinder single-acting trunk type. Steam is admitted by a special form of cam gear, which gives any cut off from zero right up to full stroke, the cylinder being 3 in. diameter by 4 in. stroke, and the normal speed 400 revolutions per minute. By sliding the cam shaft, a second set of cams is brought into operation for reversing the motor. The exhaust and inlet valves are of the mushroom type. The water and fuel feed, as well as the lubrication, is all controlled by the engine, the feed varying with the speed of the motor; the pumps are spur-driven from the motor shaft, and have a ratio of 3 to 1. The water pump and the paraffin pump are set opposite each other, and are actuated by a sliding die, a method which has the advantage of silence in running, and also has very few parts. Attached to the main spindle is a worm and wheel which operates a slow-running pump which passes lubricant to all the necessary parts of the engine. By means of a clutch, the pumps can be disconnected from the engine and worked by hand at any time, to ascertain if they are in perfect working order. Sufficient fuel and water is carried for a run of 150 miles, and the paraffin and the water tanks are filled from the outside of the car by means of a special permanently-fixed swivelling funnel. The mere act of withdrawing this funnel from its cover opens the connection to the tanks, and allows of them being filled. Furthermore, the funnel is fitted with a suitable gauze, so that the whole of the water is strained before entering the tanks. The power from the motor is transmitted in the first place to the rear wheels through a large diameter cone clutch and bevel gearing, which enables the engine to be freed from the car when turning corners or descending hills. When starting from quite cold, the clutch is disconnected and the engine is allowed to run for a short time; this gets the cylinder thoroughly hot, blows out all condensed steam and allows the pumps to start full of water, and, consequently, the car will start away at full power when required. No hand pumping is needed to start the car. The speed is controlled mainly by a pedal, actuated by the left foot and acting on the throttle. There is further provided a hand regulator in connection with the cam gear. When stopping for a short time in traffic or elsewhere, it is only necessary to depress this lever, which cuts the fire down and leaves the motor running at about thirty to fifty revolutions per minute. Although paraffin is used as fuel, the vaporiser is first made hot by petrol, one small handle on the dashboard turning on either fuel or shutting off both. Sufficient steam can be raised to run the car within seven minutes of lighting the fire; there is always enough water in the generator to give a pressure of 300 lbs. per sq. in., the usual working pressure being about 350 lbs. The brake-work fitted to the car is of metal throughout, and is of the internal expanding type, and holding with equal facility either backwards or forwards. The carriage body resembles a round-backed tonneau, but instead of entering through the back, access is gained to the rear seats by two side doors. There are many features of interest in the "Keenelet" steam car, which, however, cannot well be described without drawings.

Another additio to the list of heavy steam vehicle builders was the BRISTOL WAGON AND CARRIAGE WORKS COMPANY, LIMITED, who showed a 4-ton steam wagon with low sides, fitted with horizontal two-cylinder compound engine, the working parts and gearing being enclosed in oil-tight cases. The boiler is of the water-tube type, arranged for a working pressure of 200 lbs. per square inch. Gas coke is used as fuel. The vehicle is gear driven throughout, two speeds being provided. We hope to illustrate the vehicle in a subsequent issue. Two vehicles were shown by the THORNYCROFT STEAM WAGON COMPANY, one a 4-ton wagon for municipal purposes, the body being arranged so that not only can it be tipped, but entirely removed, and a watering-cart body fitted in its place, and a 4-ton wagon for general industrial purposes. Among the recent improvements in these vehicles are an arrangement for readily dropping out the fire bars, and a new form of valve for the engine, the latter being claimed to have not only a longer life than the old type, but to be more economical.

Another 5-ton steam wagon was that of MESSRS. E. S. HINDLEY AND SONS. This is a gear-driven vehicle, fitted with a vertical fire-tube boiler in the front part of the frame. The working steam pressure is 228 lbs. per square inch. The engine is of the compound and reversing type, running in an oil bath. The makers claim their wagon to be capable of carrying its full load up a gradient of one in eight on a good road. MESSRS. HALL AND COMPANY, of Tonbridge, displayed one of the 5-ton Foden steam wagons which have already been described and illustrated in the *Journal*. The one on view was designed for use on large estates, and represented a type which has proved very successful in practice.

GENERAL EXHIBITS.

MESSRS. W. AND F. THORN had a representative selection of their motor-car bodies. Rightly recognising the growing popularity of the sider entrance car, they have designed a good double phaeton motor body with side doors, and fitted with canopy and wind shield. Natural wood bodies are a special line with this firm, whose study of the requirements of motor-car builders and owners has resulted in their vehicles attaining special distinction. At the stand of the A. G. MULLINER MOTOR BODY COMPANY, LIMITED, we had an opportunity of inspecting the new "Planish steel" mudguards, which are capable of taking any colour, and should become popular in the trade. A good selection of single and double artillery motor wheels was also shown by this company.

Space precludes a just appreciation of all the excellent coachbuilding exhibited at the Show. MESSRS. LAURIE AND MARNER had a bold show, their vehicles being of good design and effective colouring. On another stand MESSRS. HENRY WHITLOCK, LIMITED, demonstrated their interest in motor-car work as exemplified in the Whitlock-Aster cars of 10, 12, 14, 20, and 24-h.p. This is a combination of good engineering practice with splendid carriage work. Then at the stand of the Elswick Motors, MESSRS. BARKER & Co. had a selection of their work, proving that, though somewhat loth at first to leave the orthodox ways of the carriage builder, they are now catering for the automobile industry with every prospect of success.

Some idea of the business given to the motor-lamp trade by the recent legislation might be gained from the stand of MESSRS. SALSBURY AND SON, Limited, whose selection of tail lamps, &c., was both varied and exhaustive. The "Salsbury Flario" lamps as well as the "Salsbury Dietz" lamps were shown in large numbers, while many accessories in the way of coils, accumulators, horns, voltmeters, densimeters, automobile baskets, &c., were on view.

A good display of "Bleriot" lamps was made by MESSRS. WELDHEN AND BLERIOT, who called special notice to their self-contained lamps using

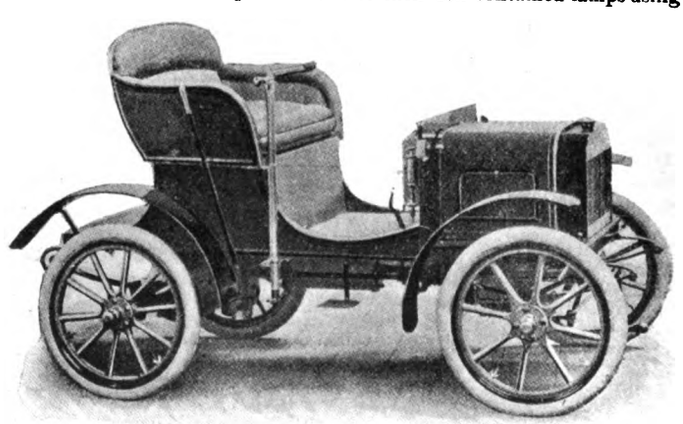

Fig. 74.—The "Vulcan" 6-h.p. Car. (See page 1022 last issue).

cartridges—a clean and effective method of generating acetylene. A good type is that with the bull's eye inserted in the centre of the ordinary glass front, thus securing a searching light ahead, while giving good illumination on all sides. The parts of all these lamps are detachable, ensuring facility for cleaning, &c. New tail lamps in accordance with the regulations now being enforced were also shown, and the useful display included a combined side lamp and horn, which attracted many visitors to Messrs. Weldhen and Bleriot's display.

MESSRS. JOSEPH LUCAS, Limited, had a large show of their "King of the Road" head and back lights, the latter being fitted with white side glass. The features of these have been often referred to in these columns. Lamp brackets for the various lamps were also on view, and several improved patterns were shown in connection with the firm's back

Digitized by Google

lights to meet the requirements of the Motor-car Act. Horns and their fixings were another important section of the display, which also included steering wheels of the flat and dished patterns, funnels, petrol squirts, and the hundred and one "motoralities" which go to make up the needs of automobilism.

COLLIER TYRES are always a notable feature of the tyre section of motor-car exhibitions, and their display was no exception to the rule. Tyres were shown which had done actual service, thus giving evidence of their reliability. The point of novelty on the stand was the new plan of attachment, which should be carefully observed by motorists visiting the exhibition at the Agricultural Hall, where a good display will be made by the COLLIER TYRE COMPANY. The new flange attachment enables the tyre to be removed in a few minutes, and will be appreciated by all practical people. The Grappler tyre was again to the fore on the stand of the HYDE RUBBER WORKS, LTD.

A capital assortment of tyre pumps was shown by MESSRS. ROSS, COURTNEY AND CO., LTD., the novelty on the stand being the three decker tyre pump, which has a compound action so arranged that the compressed air assists the operation of pumping. This enables the work of filling motor-tyres to be accomplished quickly to the highest pressure required with a minimum amount of labour. The arrangement is very simple. They also exhibited a large variety of foot pumps for inflating pneumatic tyres, lubricating oil pumps for motor-cycles, and motor-cars of various patterns. Sight feed lubricators for motor-cars, filler caps and collars, throttle valves, unions, levers, petrol gauges, cocks, and all kinds of screws, terminals, turned parts, machined parts and stampings for the various requirements of the motor trade were also displayed.

THE COSI CAR COMPANY, LTD., showed a useful attachment for fixing to a motor-cycle, so that it can be transformed into a small car. The idea is one that has been frequently advocated, and as it has already been described in our columns, further description is unnecessary now.

The Keystone belt and pulley brought out by MESSRS. JOHN TULLIS, LTD., was on view. This is the invention of Mr. H. W. Stones, of Lincoln. The belt is of hide rivetted with copper, so that each strip of hide has its share of the work, while the grip is mainly on the flat slotted surface connecting the two flanges.

MR. C. J. PAFFARD'S stand was a centre of attraction by reason of the presence of Dr. Winter's speed indicators, which present several good points, including a combination of the counting of the revolutions as in a cyclometer and the measuring of time. The rotations of the car wheel are communicated to a wheel in the instrument (but at a greatly reduced speed) by means of worm gearing and bevelled cogs; the amount of rotation of the indicator wheel in a given time shows, therefore, the rate at which the car wheel is revolving. The revolutions are counted by a simple piece of clockwork, consisting of only three spindles—the mainspring spindle, escapement wheel spindle, and balance wheel spindle. This clockwork is automatically wound up by the movement of the car, and as it unwinds it measures off the periods of the two seconds during which the revolutions of the car wheel are communicated through the indicator spindle to the hand on the dial.

Seddon's motor tyres were shown by the BRITISH MOTOR TYRE COMPANY. These are made from red rubber, and in the construction of the tyres each strand or cord is dealt with separately by unvulcanised rubber being forced between each. They are made taut under great pressure in order to take their equal proportion of the strain, with the result that several layers of the cord are practically moulded into one. The tyre is self-sealing, and has attracted considerable attention from practical motorists.

The Reilloc padded solid tyre was shown to us in section on one of the stands by MR. ARTHUR COLLIER, and its presence at the forthcoming Motor-car Show will prove a minor feature of some interest. It is constructed in two parts, there being an outer cover and an inner rubber pad. This outer cover is detachable, and is secured to the wheel by fabric of Egyptian cotton, much as a pneumatic cover is held. The inner pad is made of rubber, taking the place of the ordinary air tube, so that when the tyre is worn down only the outer cover will need renewal, thus saving one-half the cost of rubber when new tyres are needed, and even the outer cover can be re-treaded. There is no waste of rubber inside the rim, and all the rubber is utilised for cushioning the car. A thick steel rod, fitted with left and right hand screw threads, is united by a strong nut, thus enabling the outer cover to be pulled tightly down on to the rubber pad, forming a good adjustable fastening.

The "Bridge" accumulators and high-speed trembler coils were shown by the ELEPHANT CHEMICAL COMPANY.

MESSRS. W. R. MCTAGGART, LTD., had a stand where a representative of the Streatham Motor Company showed us the new model of the F. N. motor-bicycle. This has a 2¾-h.p. motor in a vertical position, somewhat advanced, so as to increase the distance between the pulley and the rear wheel. A special patented pattern of the F.N. carburettor has been fitted. This is of the constant level type, giving uniformly good results under all conditions. A new contact breaker is now fitted, the new arrangement requiring only one terminal on the exterior to attach the accumulator wire. The reservoir holds sufficient spirit for a trip of about 150 miles, the accumulator furnishing enough current for 600 miles. A new design of Bowden brake is now provided on the rim of the rear wheel. In lubrication a new arrangement is being introduced, enabling the cyclist to lubricate the motor, whilst riding, by moving a simple lever, and to thoroughly lubricate the piston when the motor is running slowly and needs an abundant lubrication. At this stand was a good type of fore-carriage, notable by reason of the ease with which it can be steered, and the efficient way in which the current of air beneath is directed on to the engine.

MESSRS. G. STRAUSS AND COMPANY, LTD., the representatives of the Aix-la-Chapelle Steel Works, had a display of the Fafnir engines, change speed gears, and rear axles.

The "Giant" tyre was shown by the SHREWSBURY AND CHALLINER TYRE COMPANY, LTD., the idea being to secure a tyre capable of carrying heavy motor wheels. The company also exhibited their automatically interlocking artillery wheels, the spokes of which are designed to overcome the liability of working loose, etc., the same being recessed and interlocked in such a manner as to make a perfectly rigid centre, independent of the metal hubs.

The motor lawn-mowers of MESSRS. RANSOMES, SIMS AND JEFFERIES, LIMITED, were shown in various sizes, notably 42 in., 30 in., and 24 in., the latter being the smallest size. It is driven by a 2¾-h.p. engine, and with its help an intelligent gardener can easily get over two to three acres a day. The 30 in. machine has a 3½-h.p. motor. The power is conveyed to the cylinder by chain gear through a reducing arrangement, which is furnished with a simple gear for starting and stopping the machine quite independently of the motor. There is also a separate clutch for putting the cutting cylinder out of gear when it is not required for cutting. The largest machine has a 6-h.p. petrol motor, chain gear being utilised in connection with the power transmission. The driver sits on a spring seat behind the machine, his weight being carried by a pair of steering rollers. He has control over every part of the machine, the handles and lever for starting, stopping, steering, and emptying the grass-box being arranged so as to be easily within reach from the seat. The height of cut can be easily altered. When not required as a grass cutter, the machine can be used as a roller; and when needed for heavy rolling the cutting cylinder can be removed and extra weight easily added by separate weights; 7 cwt. or less can be added in this way. A pulley can be attached for using the motor for other purposes.

THE TONI TYRES, LTD., exhibited pneumatic tyres of that name, the construction of which is apparent from the accompanying illustration. The tyre consists of a cover and inner tube, the main feature being the method of attachment. This is effected without any bolts passing through any part of the tyre. The square beads are held firmly at every point round the wheel by pressure of the flanges, and it is claimed that there is no possibility of any creeping or displacement of the tyre. The pressure of the flanges on the beads is obtained by a series of bolts through the flanges and the intervening felloe without touching the tyre. The flanges can easily be taken off, and the tyre and inner tube removed within a few minutes, by simply unscrewing the nuts on the ends of the bolts. The replacing of the tyre and the flanges can also be easily accomplished on a properly constructed wheel, as all the parts of the flanges are interchangeable.

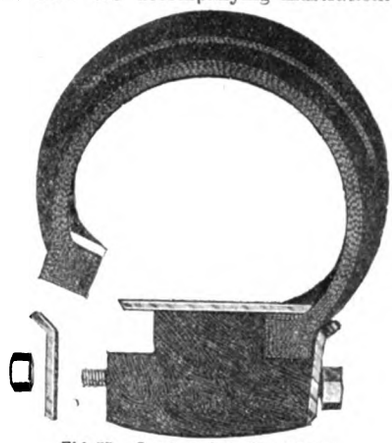

Fig. 75. Section of the Toni Tyre.

MESSRS. PHILIPP AND COMPANY, who are taking up several English agencies in addition to those with which they have been familiarly connected showed a new engine made by Messrs. Lloyd and Plaister. On their stand we also noticed the A.B. axle with ball bearings, and the M.A.B. gear for chain or cardan drive, all of which are fitted with ball bearings. A good assortment of lubricators for motor-cars and motor-cycles was shown, and Messrs. Phillip and Company made ample demonstration of their capacity to cater for the trade.

MESSRS. CASSWELL, LTD., showed a patent two-speed gear box, giving also a free engine for motor-cycles, tricars, etc. They also had a good display of the Imperi Rex motor-cycles, Rex tricars, Trimos, fore-carriages, Minerva engines, Abingdon motor-cycle fittings and frames. A new mica sparking plug was also shown. There was also seen Dick's Balata motor belt (Messrs. Casswell, Ltd., being their sole London agents), and, in fact, every up-to-date motor requisite was on view.

At the stand of the CLIPPER PNEUMATIC TYRE COMPANY were the "Clipper" motor tyres, the "Clipper-Continental" motor tyres, and the "Clipper-Michelin" motor tyres. Special interest was shown in the new patent "Clipper-Continental" motor tyre, with flat tread.

MESSRS. ALFRED HERBERT, LIMITED, Coventry, had a good display of their machine tools, such as are being adopted by most of the leading automobile makers in the country. Of special interest were the No. 6 capstan lathe and the combination turret lathe, the latter being extensively employed for dealing with the heavier parts of automobiles.

A collection of accumulators of all sizes was shown by the SOLA ACCUMULATOR COMPANY.

LEWIS'S, of Liverpool, came into prominence at the show with a good selection of motor clothing, attractive items in their display being jackets, overcoats, breeches, caps, etc., in leather, waterproof tweed, and other

Digitized by Google

cloths. Fur coats in Russian foal, seal, cheyrette, reindeer, etc., were also included on their stand, the exhibit being completed by a large assortment of accessories, lamps, horns, etc.

In addition to the Royal Sirdar-Buffer tyres, the SIRDAR RUBBER COMPANY exhibited twin tyres for public service motor-omnibuses weighing up to 6½ tons. They also showed their special wheels made of cleft oak, built for voiturettes, touring cars, and omnibuses, wire wheels and carriage wheels of all sizes, and Sirdar pneumatic tyre covers compressed both laterally and longitudinally, so that the cuts in any direction close up. There was also a Sirdar pneumatic tube, so constructed that it cannot get nipped by the cover when fitting the tyre. When inflated, this tube is under compression, so that it is very difficult to puncture.

The DININ accumulators for cars and motor-cycles were an attractive display, and attention was drawn to several excellent batteries for lighting the lamps of carriages, etc. These well-known accumulators have long ago proved their reliability. In addition to accumulators, M. Dinin also exhibited charging boards for recharging accumulators, voltmeters, amperemeters, and the like. We may add that the business is looked after by M. A. Godin, so far as this country is concerned.

"A thousand and one things"—to quote a familiar phrase—were shown by MESSRS. A. W. GAMAGE, LTD., whose representative collection was a liberal education as to what a motorist really wants—as well as many things which he likes to possess. In lamps, a burning question just now with motorists, was an infinite variety, a three-cornered pattern being prominent. Back lights for illuminating numbers were also on view in comprehensive variety. The Duplex tyre lever, illustrated herewith, was another speciality. The new motor-bicycle on view had a 3-h.p. engine instead of that of 2½-h.p. hitherto fitted. It is now fitted with a trembler coil, exhaust lift, and throttle, otherwise retaining the well-known features of this popular machine. A pump actuated horn shown by Messrs. Gamage will be appreciated by those who have had trouble with the bulb pattern. Several new spanners and similar tools were on view, and drivers of cars should be interested in the licence holder brought out by the firm. This is something like the ordinary season ticket case, with a celluloid face, so that the licence is always ready for inspection, and need never get into

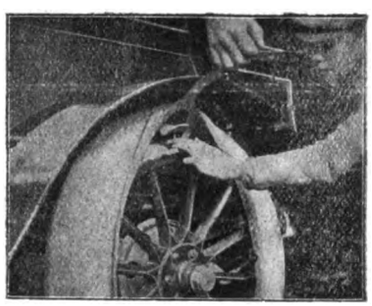

Fig. 176.—Gamage's Tyre Lever.

a dirty condition. One of the neatest devices on the stand was the "Cossor" petrol gauge and test, which affords an accurate and easy means of ascertaining both the quantity and density of the petrol in the tank of any car or motor-cycle. By a simple arrangement the gauge automatically empties itself when shut off from the tank. The float is clearly marked with three red lines, which indicate the best density for summer and winter, as well as the limit. We may add that Messrs. A. W. Gamage, Ltd., did not exhibit cars, reserving their new types for the 1904 season for the exhibition at the Agricultural Hall.

MESSRS. J. G. STATTER AND CO. made a good show of their Lampe de Luxe, which is now made in three types. One of these gives an approximately parallel beam of light; the second has a fixed mirror, and also a device which, on pressing a button, applies a shade according to the suggestion made by several county authorities. The third has a mirror which can be set to give either a parallel or a divergent beam, the movement being controlled by a Bowden cord actuated from the steering pillar on the dashboard. Thus the driver can have the command of a parallel light for fast driving, or a divergent beam for driving in traffic. Messrs. Statter and Co.'s headlight is charged by means of a cartridge which, when exhausted, is thrown away, and another one inserted. This system has been under trial for nearly twelve months with satisfactory results. The water contained in the lamp is not fouled in any way, except so far as it may be said to be fouled by the absorption of acetylene gas. No lime, however, is allowed to escape from the carbide, and the water remains clear. If a quantity of it be evaporated no deposit is left. This is important to automobilists, in case of an accidental splash on the paint of their car. It is moreover useful, since it is not necessary to renew the water in the lamp, but merely to add a little from time to time to make up for that lost in combining with the carbide calcium. The cartridges are hermetically sealed, but may be quickly unsealed for use. The firm also showed their jacks for light and heavy cars.

At the stand of the EAST LONDON RUBBER COMPANY the "Kerry" motor-bicycle was a conspicuous exhibit. This, with its 2¼-h.p. engine placed in the vertical position, is becoming a popular machine. Transmission is by a V belt, and there is an improvement in placing the switch on the handle-bar, thus doing away with the switch handle. The company are also bringing out a 2¾-h.p. model de luxe and a 3½-h.p. machine for racing purposes. Fore and side cars were also shown at this stand.

The B.S.T. dry storage battery was shown by the BRITISH STEAM TRACTION SYNDICATE, LIMITED, this being, claimed to work equally well in any position, and adapted for either lighting or ignition work. The battery contains no free acid, and for the plates a special form has been adopted. The active material is firmly keyed to the plates, which can be charged at an unusually high rate. They have also the properties of lightness and durability. The B.S.T. battery is charged in the usual way, from a dynamo, lighting main or primary battery, and is made in various sizes from 8 to 30 ampere hours for carriage lighting, or they will give 25 per cent. more on ignition work.

The "living pictures" which MESSRS. ALFRED DUNHILL, LIMITED, have introduced into their displays at the exhibition have become a popular feature of the tailors' corner, and they managed to introduce a novelty into their display. Instead of the ordinary "dummies," men and women were attired in motorists' garb, and, seated on a car, gave visitors a good idea of the actual appearance of new costumes on people when in motion. Among the novelties shown were a shower-proof motor-cyclist's jacket, a double-breasted garment of covert coat length, with a deep extension storm collar, the sleeves being fitted with the usual windcuffs. A good style of lady's waterproof motor-coat was also deserving of notice, giving a much smarter appearance than the ordinary waterproof. The stand of the collar is finished with two straps of elastic, one passing through an opening on the opposite side of the collar, terminating at the back of the neck with a large hook and eye. Thus the collar is held close, and it is impossible for rain to penetrate. A new combination of fur storm collar, cape, stole, and muff was another novelty; while the combination of cap and goggles is an idea that will commend itself to racing men. Included in the largest and most comprehensive assortment of motorists' goods were leather coats, jackets, overalls, oilskins, fur outfits, skin coats, waterproof knee aprons, and combined leggings and gaiters. In accessories the display was as full as in the tailoring department.

MESSRS. LOWE, BEVAN AND CO.'S display was complete in all kinds of motor body accessories, canopy fittings, spring clips, door handles, etc. Some good designs of door furniture were comprised in the display, as well as a new design in carriage steps, particularly adapted for motor-cars. "Guineo," a new metal for motor-fittings, which is claimed to have the advantage of being non-corrosive; motor-rugs, aprons, lamps, &c., completed an interesting display.

A motor-launch with a 4-h.p. engine was shown by the GROSVENOR ENGINEERING WORKS, which is entering into the study of motors for launch purposes with much chance of success. MESSRS. SIMPSON, STRICKLAND AND CO., LIMITED, were also represented in the marine motor department, a 30-ft. yacht's launch being the leading feature on their stand.

M. ANDRE A. GODIN had a display of the "Ducellier" lamps for automobiles. These are made in all sizes for various types of cars, the illuminating power being paraffin, acetylene or electricity. New projectors and headlights for large cars were also shown, as well as some new automatic generators, which motorists should examine for themselves at the forthcoming show. A good assortment of horns of new shapes and designs completed M. Godin's exhibit.

A good display of engines, gears, coils, radiators, axles, lubricators, etc., was made by the BEGBIE MANUFACTURING COMPANY, LTD., who will also be prominent at the forthcoming show at the Agricultural Hall. After being shown at this exhibition, many of the articles will be shipped directly to the St. Louis Exhibition. Among the exhibits were the "Aster" engine, fitted with mechanically-operated valves. These are made in 10–12, 14, 16–20, 24, and 30-h.p. sizes, the three latter being of the four-cylinder type. The "Aster" three speed and reverse gears for chain drive, and supplied complete with differential and clutch, were also shown. On the stand was a complete *chassis* such as the Begbie Company supply fitted with Aster engines of 10, 12, 14 or 20-h.p. In Begbie-Audin radiators was a good selection, including the new type thermo-syphon radiators, all being characterised by good cooling properties, combined with lightness. Water-circulating pumps, Longuemare carburettors, coils, lubricators, etc., were also shown, as well as the Begbie-Oleo sparking plug, the advantages of which are that it is made very short, and of thick porcelain. The interior of the porcelain is shaped so as to prevent fouling. There was also displayed the Begbie-Aster motor-launch set—a department to which great attention is being given. These sets are supplied in 6, 8, 10, 12, 16 and 24-h.p.

Two splendidly-made *chassis* of respectively 15 and 25-h.p. were to be seen at the stand of MESSRS. CHARRON, GIRARDOT AND VOIGT. The 15-h.p. car is on similar lines to last year's models, with the exception of a number of detail improvements, these including the new ball-bearing axle and an improved radiator with fan. The 25-h.p. car is a new model. The frame consists of a square steel tube filled with wood. In addition to the usual springs, a transverse spring is provided at the rear. The motor comprises four cylinders with mechanically-operated inlet valves. In place of the steel cylinders of last year, separate cast cylinders are now employed. They are, however, of special design, having openings in the side closed by removable bronze plates, which not only allow the engine to be built on a smaller crank chamber, but also permit of access to the water jackets. The inlet valves are driven off the same cam shaft as the exhaust valves, with which they are interchangeable; the crank shaft of this engine runs on ball bearings. The gear box, which gives four speeds and reverse, with direct drive on the fourth, has been newly designed; in it ball bearings are utilised. A new design of exhaust box adds to the silent running of the car.

Digitized by Google

PNEUMATIC TYRES.

By J. D. Siddeley.

A slight knowledge of the manufacture of the pneumatic tyre must be of advantage to the owner of a car, and thereby, incidentally, of pneumatic tyres, to enable him to, at all times, get the best results from the use of his car. It has been my experience that a certain proportion of tyre troubles could have been avoided had the owner of the car been conversant with certain elementary principles of tyre construction. The two important problems before the tyre manufacturer, apart altogether from the many incidental details, are, primarily, to manufacture a casing (this being the technical expression for the canvas or air-restraining portion of the tyre) which shall in all ways satisfactorily accomplish the duties it is called upon to perform; and, secondly, to so blend a mixture of india-rubber which, when vulcanised, will ensure the india-rubber and the canvas becoming homogeneous, and, at the same time, be capable of withstanding the friction created during the running of the car ensuing from the driving effort.

Dealing first with the casing, this is composed of cotton cloth, made of long fibre yarn. For this purpose the quality known as "Sea Island" is most favoured, this having the longest staple of any known cotton yarn, and therefore being expensive. By "staple" is meant the capacity to which the fibre can be drawn out. Next in favour comes Egyptian yarn, which runs the Sea Island variety very close for length of staple, while many tyre manufacturers contend that it gives more satisfactory results, on account of being slightly tougher, and therefore capable of withstanding greater strains. In the early days of tyre manufacture linen was used for this purpose, as being the stronger; but it was discovered that what was required was not mere strength, but flexibility, linen casings invariably cracking at the point of flexion, on account of the internal bending strain of the tyre. This point occurs a little above the halfway point on the walls of the tyre. If you look at the tyres on a car you will see a slight flattening out, and a sharper bend as the tyre comes round the point where it is in contact with the road to the walls. That point is the point of danger in all pneumatic tyres, for there is a constant saw-like action going on there. The greatest care is required in preparing the cloth before it can be made into the casing, as it is absolutely essential that this should be quite dry; otherwise, in the process of vulcanisation the heat required to vulcanise the tyre tends to convert any moisture it may contain into steam, thus preventing the various folds of cloth uniting properly. The cloth being dry, it has first to go through the frictioning process. This consists of thoroughly impregnating the cloth with rubber solution, this solution being naturally of a vulcanising nature. The canvas being spread, it is then cut into diagonal strips—that is to say, strips of tyre lengths which have been cut across the threads at, practically, an angle of 45 deg. This plan is followed to enable the canvas to adapt itself to the bridge shape—in fact, it is regarded as a practical impossibility to get the necessary amount of shape on a tyre made with the canvas cut quite straight. A further advantage in cutting the canvas in this particular direction is obtained in that it is found that the canvas cut in this manner prevents the tyre rolling from side to side when fitted to the wheel. If a tyre were made with the canvas cut on the straight, it would not matter how tightly inflated it might be, it would still roll from side to side, and at the same time there would be a considerably greater loss of power. In the case of canvas cut diagonally, we have short strands anchored on opposite sides of the rim and tangentially, and so with a direct resistance to side-pull, but with a straight cut canvas there would be no such anchoring, and every strand would be free to move from side to side. A pronounced difficulty in connection with this class of work is that we have so much more circumference to deal with in the tread than we have at the sides. The canvas has to be stretched on the tread, and consequently wrinkles, which develop at the sides, have to be smoothed out as far as possible to make a proper tyre. A further advantage in connection with the construction arises, in that at the bend (I am speaking now of the ordinary beaded-edge tyre), where the greatest wrenching strain arises, the cloth is in its normal state, and better able to withstand the strain which arises at that point. In addition to the difficulty in connection with this portion of the manufacture of the casing, the complicated process of forming the bead of the cover is done in the same operation. Upon the regularity of the bead and its being shaped correctly and at even distance from edge to edge throughout the tyre, a good deal of the durability of the tyre—certainly, its powers to stay on the rim when inflated to an enormous pressure—depends. The bead is composed of hard rubber, run through a die, and is, like all the rubber used in the construction of the tyre, of a vulcanising nature. This beading is so mixed that when subjected to the same heat as the remainder of the casing it becomes harder, and thus gives the necessary stiffness to the bead. The strength of the tyre entirely depends upon the casing, and this is arrived at in the ordinary type of tyre by the numbers of folds of canvas which are incorporated in the manufacture of the casing. Dealing with the standard makes of tyres, the number of folds of canvas are as follows:—Three folds of light cloth for voiturette tyres. Three folds of heavy cloth for light car tyres. Four folds of heavy cloth for ordinary touring car tyres. Five folds of heavy cloth for heavy touring car tyres.

These weights are found to give a sufficient strength of casing to the cover, and not to interfere in too great a degree with the elasticity of the tyre.

Assuming that we have our completed casing, which is ready for receiving the rubber, I will now deal with the manufacture of the rubber. On arrival at an india-rubber factory the blocks of rubber are cut up into small pieces and then carefully boiled to remove all impurities and dirt. After being boiled the small pieces of rubber are dried and sent to the mixing-room. When the raw rubber arrives at the mixing department, sulphur is served out, this being used for vulcanising, and at the same time other ingredients which are used to assist such vulcanising, or to toughen the rubber, or to cheapen its quality by mixing with the pure rubber and vulcanising ingredients a cheaper rubber and other chemical preparations. After being mixed, the rubber is then taken to be calendered. From the calender the rubber goes to the cutters-up, who cut it into the necessary strips and pass it on to the tyre-makers proper. These secure to the casing the necessary thickness or amount of rubber such as may happen to be required for the tyre which they are then engaged in making. The tyre, having passed through these various departments, is now a complete cover, ready for vulcanisation. After the tyre has been cured by being subjected to the necessary heat, the tyre is taken out of the mould, forced off the "former," and is then complete beyond the necessary trimming of the superfluous rubber which will have been forced out of the mould through passages provided for this purpose, and, beyond the necessary amount of handling, is then ready for use. Should, however, the tyre be of the type fitted with a tread, it has to undergo a further cure, this being generally effected in the following manner:—The tread is built up separately, and after being solutioned to the casing, the whole cover is wrapped upon a suitable "former" with canvas—hence the rough marks always seen on the tread of such a tyre, these marks being formed by the canvas wrapped round the cover to secure the tread during the second process of vulcanisation.

Dealing next with the manufacture of inner tubes, these are made on two systems. By one system the mixed india-rubber is put into a machine much resembling a sausage machine, from which the uncured rubber issues through a suitable die in the form of a tube. In the other system, sheets of mixed india-rubber are cut up into strips, put on to tubular mandrils, and joined up by wrapping them with canvas. Probably the manufacture of india-rubber requires the use of more steam than almost any other industry, as it is the heating agent for the curing of all rubber. It is only to firms such as the Continental Company and other houses in an enormous way of business that one can look for developments of this industry. The enormous expense incurred in experimenting, the slightest slip in issuing a batch of tyres in which a mistake has been made in construction, requires generous treatment, and in dealing with such trouble when arising from such mistakes immense resources are needed—only at the command of large companies. Thus far I have dealt only with the ordinary form of tyre, but I feel that it is necessary to speak specially of one tyre of which we have heard a good deal in the last few months—I refer to the Palmer cord tyre. There is no doubt in my mind that a tyre of this construction will be less open to the attacks of one of the great enemies of motor tyres—friction—than the ordinary type, for the simple reason that there are only two layers between which the friction can arise, instead of four or five. As an item of interest some experiments have shown that the heat developed in a tyre which has been running for two or three hours on the road may reach as high as 185 deg. Fahr. A further point which must demand close attention until we have arrived at a satisfactory solution to the problem is the provision of an effective non-slipper and protector. While I am speaking the "Concours d'Antiderapants" is being carried out across the Channel, and the entries for this show that the tendency is to look to iron or steel mingled with leather or rubber, or both, to provide the effective non-slipper; but we must not forget that in all such attempts we have to face the effect of damp on the tyres, and the rusting of their iron immersions or attachments.

I desire to give a few hints to motorists in general, which may perhaps be of some little value in selecting their tyres. Taking, first, the covers, do not be led away with the idea that many folds of canvas necessarily means strength. Secondly, beware of the tyre having wrinkles on the inside of the cover. Thirdly, never purchase tyres having fat edges—that is to say, in which the lips bedding in the rim do not slope away to a knife edge. Regarding tubes, the endless variety are always uncertain. Under the very best manufacture there must be thick and thin patches, and this is their vital defect. I have a personal preference for red tubes instead of grey ones, solely because with the red tube one can see at a glance whether this has been nipped in any way in attaching the tyre to the rim. Any other pronounced colour would serve equally well, save that it could only be produced by using a pigment in the rubber, while red and grey rubber are produced by natural vulcanising agents. To answer a common question, I may also add that there is no difference whatever between the qualities and properties of red and grey rubber. Finally, with regard to the use of the tyres, I strongly advise every motorist to stop and repair any serious cut in his tyres immediately he notices it, even if this be at some personal inconvenience. I also advise everyone to carry with him a supply of rubber and canvas gaiters.

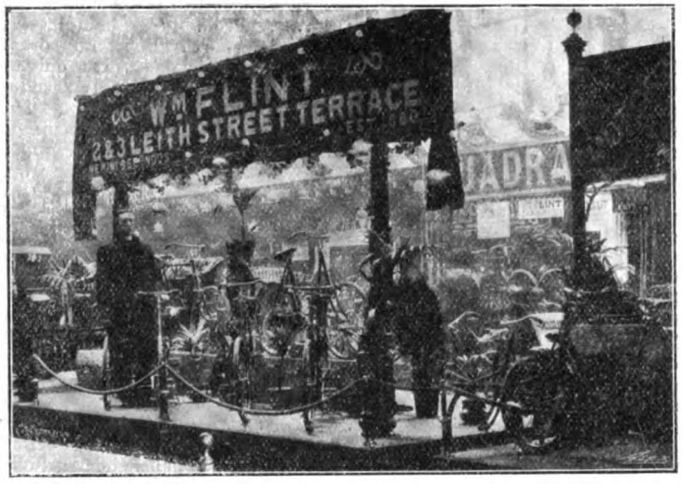
* From a paper read at the Automobile Club on February 25th, 1904.

LICENCE ENDORSED.

Sidney Keeble, driver to an officer at Shorncliffe, was, at Sevenoaks Police-court, fined 10s. for recklessly driving a motor-car through Sevenoaks High Street, on February 1st. The defendant travelled at an estimated

Digitized by Google

speed of from fourteen to sixteen miles, attempting to pass between two vans, one of which was overturned and the occupants were injured. The magistrates considered the case a very bad one, and endorsed the driver's certificate.



ENTRIES FOR SIDE-SLIP COMPETITION.

THE following firms and gentlemen have submitted entries for this competition to the A.C.G.B.I.:—

Mr. Mark Vivian.
The Wilkinson Tyre and Tread Company.
The Continental Caoutchouc and Gutta Percha Company.
Mr. Alexander Nicholson.
Commander Chas. T. Scott.
Messrs. Rourke and Horsburgh.
Mr. Wm. Cross and Sir Chas. Ross.
Mr. H. Taylor-Stephens.
Sainsbury's Anti-Skidders, Limited.
Mr. S. H. Cavendish.
Mr. E. Midgely.
Mr. Wm. Hunt.
Mr. Samuel Butler.
Mr. W. Maitland Edwards.
The Gare Patent Tyre Company.
M. Henri David.
Messrs. Grose, Limited.
Mr. W. H. Manning.
Mr. John Harrington.
The Parsons Non-Skid Company.
Messrs. Wm. Jenkinson and Co.

EXHIBITION AT EDINBURGH.

THE seventh annual motor and cycle exhibition which opened in the Waverley Market, Edinburgh, on Friday last week, contains by far the largest display of motor-cars, motor-cycles and accessories so far seen in Scotland. Fully 150 cars, in addition to a large number of motor-cycles, are on view, these including all the leading English and Continental types, already fully dealt with in recent issues of the *Journal*. One of the most interesting stands is that of Stirling's Motor Carriages, Ltd., on which is shown a two-

A Corner of the Exhibition.

Photo by] [*Fraser & Elrick.*

ton petrol lorry similar in type to the three-ton vehicles which the firm is now building for the War Office. A 20-h.p. omnibus for fourteen passengers, with luggage rail on top to carry half a ton of luggage, one of a number built for the Earl of Leitrim for the purpose of maintaining a regular passenger service on a thirty-mile route in the neighbourhood of Strabane, County Tyrone, is also displayed. Mr. William McLean, of Glasgow, shows a new 12-h.p. tonneau car of his own construction. It is known as the "St. Vincent," and is fitted with a 12-h.p. two-cylinder Aster engine and cardan shaft transmission. Altogether the exhibition, which closes to-day (Saturday), reflects much credit on the organisers, and the enterprising managing secretary, Mr. A. K. Dempsey.

MOTOR-VAN AND WAGON USERS' ASSOCIATION.

THE first general meeting of members of the Motor-Van and Wagon Users' Association was held at 119, Piccadilly, London, on the 24th ult. Among those present were Colonel R. E. B. Crompton (in the chair), Messrs. R. W. Wallace, K.C., E. Shrapnell Smith, T. Staplee Firth, George Monro, jun. (Motor Cartage Company), Mr. Douglas Mackenzie (Motor Transport Company), W. G. Lobjoit (W. J. Lobjoit and Sons), R. H. Griffiths (Idris and Co., Limited), J. Kitching (Debenham and Co.), F. C. A. Coventry (Great Western Railway), J. Farmiloe (T. and W. Farmiloe, Limited), John Allen (Oxfordshire Steam Ploughing Company), O. Cernett (French Ashphalt Company), R. D. Dundas (Dundas and Seton), and Mr. Rees Jeffreys. The Secretary having read the notice convening the meeting, the draft rules, as formulated by the Provisional Committee, were considered and amended by the meeting, and adopted. It was resolved that the first Executive Committee of the Association shall be comprised of the following:—Messrs. E. R. Calthorp, E. Shrapnell Smith, H. H. Humphreys, D. Mackenzie, G. Monro, jun., F. C. A. Coventry, A. J. Clay, L. H. Baxendale, J. Farmiloe, J. Kitching, W. G. Lobjoit, T. W. Thorpe, R. H. Griffith, Alsager Vian, and Lieut.-Colonel Mark Mayhew, with the following as *ex-officio* members:—Colonel Crompton, C.B., T. Staplee Firth, R. W. Wallace, K.C., and W. Rees Jeffreys. The Executive Committee to have power to add two names representative of firms using motor-delivery vans to this list. Messrs. A. W. Barr and Co. were elected auditors. A meeting of the Executive Committee was held immediately after the general meeting, at which the following appointments were made:—Hon. treasurer, Colonel R. E. B. Crompton, C.B., R.E.; secretary, Mr. W. Rees Jeffreys; solicitor, Mr. T. W. Staplee Firth. The question of the election of a president and chairman was postponed.

CLUBS AND ASSOCIATIONS.

HERTFORDSHIRE.

AT a committee meeting of the Hertfordshire Automobile Club, held in Watford on the 26th ult., it was decided to become affiliated to the A.C.G.B.I. under Scheme II. It has been decided to contest the action of the St. Albans Corporation, which is seeking to impose a ten-mile speed limit over the entire area of the city. A formal letter of objection was forwarded to the Local Government Board. The chairman and hon. secretary drove over to St. Albans on the following day in order to beat up local opposition to the application. A number of protests from motorists living in St. Albans have been forwarded to the Local Government Board. The club has obtained from the local candidates their views as to automobilism generally, and has been assured that they object to the underhand practice of the police in trapping motorists on deserted roads. Happily Hertfordshire is free from this noxious practice.

CASES DISMISSED.

MR. JAMES MCKELVIE, of Clifton Terrace, Edinburgh, was summoned at Guildford for driving a motor-car at Ripley at the rate of over twenty miles an hour. Sergeant Jarrett admitted that eleven out of twelve stop-watches supplied to the police of that district had been sent to London to be seen to. The case was dismissed.

WILLIAM HAYNES, driver, in the employ of the Folkestone, Sandgate, and Hythe Motor-Car Company, has been summoned for not having a light fixed on the back of the motor-car to show the number. Defendant, in reply to questions put to him by Mr. Minter, said that since the regulations had been passed he had had a number on the back of the car, and a lamp in order to illuminate it at night time. He lighted the lamp before he started from Cheriton. For some time past the Cheriton road had been in a very bad state so far as carriage traffic was concerned, from repairs going on there. It had broken the springs of the motor-car on two occasions. The vibration from the state of the road caused the light to go out. W. H. Willis said he was the manager of the Folkestone, Hythe and Sandgate Motor Company. He produced one of the lamps used by the company. They burnt paraffin oil and would burn from ten to twelve hours. When alight they illuminated the number behind the car. He corroborated last witness with regard to the springs of the motor-car being broken on account of the state of the road. The chairman said under the circumstances they had decided to dismiss the case. They wished defendant to understand, however, that they were not going to allow that always. If the lamps were continually jolting out the company would have to find better ones.

DAMAGES AGAINST A DRIVER.

AT the Bristol Guildhall, the Under Sheriff, with a jury, has heard an action which Joseph W. Hall, of Oldland Common, brought against Thomas Watts, of Elmore, Gloucestershire. The plaintiff claimed £10 for personal injuries, and £100 for damage to a motor-car, alleged to have been caused by the negligent driving of the defendant or his servants on December 15th, at Gloucester. Mr. Phillips explained that the plaintiff was a commercial traveller, and used a motor-car in his business. On December 15th he was driving from Bristol to Gloucester at about 6 p.m., and met the defendant, who was driving a cart. The plaintiff had a lamp on each side of the motor-car and a large acetylene lamp in front, and he was on the proper side of the road. The defendant, who had no lights, drove into him, the result being that the car was an absolute wreck. Judgment having gone by default, the only question the jury had to decide was the amount of damages. The plaintiff gave evidence in support of the claim. Mr. H. B. Lowe said the car was worth about £200, and the repairs would cost about £92. The jury assessed the damages at £68.

DIRECTORY OF NUMBERS.

PRESSURE on our space again compels us to hold over both the "Directory of Numbers" and the list of "Dealers' Marks," considerable additions to which have been made since the publication of the last lists.

THE

Motor-Car Journal.

[VOL. VI.] LONDON, SATURDAY, MARCH 12, 1904. [No. 262.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

SIR OSWALD MOSLEY, whose genial features we are able to reproduce by the courtesy of our friends of the *Pall Mall Gazette*, is the president-elect of the Hackney Horse Society, whose annual show has attracted many visitors to the Agricultural Hall during the last few days. He is an authority on horseflesh and a convert to automobilism. In fact, despite his position in the Hackney Horse Society, he has declared to our contemporary his intention of selling all his horses save two and becoming a motorist at an early date. Such a confession is interesting as demonstrating the advance now being made by automobilism, and also as evidence of the capacity of country gentlemen to recognise the trend of the age. Sir Oswald has seen the good work done by the agricultural motor, and is convinced that the motor vehicle is destined to play an important part in resuscitating the fallen fortunes of the countryside.

◆ ◆ ◆

English or Roman.

MR. INVERNESS WATTS had better be content with plain English figures in place of the Roman numerals which have led to his appearance at the Hailsham Petty Sessions. On his identification plate he used the figures CCXXXIII. instead of the regulation number 233. It was made clear by the Local Government Board that the figures were to be such as could be plainly seen and read by a policeman. The adoption of Roman numerals was certainly contrary to the Act, and, as will be seen from our report on another page, somewhat expensive when Major Lang's men are about. This can hardly be regarded as a piece of police impertinence, although the chief constable is to have a car provided him by the East Sussex County Council, and paid for out of the fines imposed on motorists last year.

◆ ◆ ◆

A Paper at York.

AT a meeting of the York and District Motor Club the other day, Mr. J. E. Gibbs, of York, read a paper on the progress of the motor industry during the last few years. Having pointed out the reliable character of the modern motor-car, he touched upon the law as regards automobiles, and deplored the fact that the recklessness of certain motor drivers had certainly branded all motorists as ticket of leave men. Notable improvements had been effected in frames and wheels, and with regard to tyres, he mentioned the Collier as having proved itself to have very great immunity from punctures in several important trials. Mr. Gibbs deplored the fact that the majority of motorists took little care of their tyres. After running in wet weather, these should be carefully dried, especially where the covers touch the rim, and if they are occasionally removed and the edge of the rim kept free from rust, the life of the tyre will be materially increased. Reference was made as to the characteristic features of the Gobron-Brillie motors, and the engines in the Lanchester car. Dealing with carburettors, those used on the Crossley and Wolseley cars were explained, and considerable attention paid to the transmission gear. Steam and electric vehicles were not overlooked, and altogether the paper proved a very comprehensive survey of the state of automobilism at the present time.

◆ ◆ ◆

Saturday, March 19th.

ON Saturday, the 19th inst., the Ninth International Automobile Exhibition will open at the Agricultural Hall, London, and will continue during the following week. Social functions will include a dinner by the A.C.G.B.I., the reception of the Ladies' Automobile Club, and the annual meeting of the Motor Union. Apart from the interest of the Exhibition, these events will bring a large number of influential motorists to the Show, and there should be no uneasiness felt as to the attendance. This will be larger than ever before known, and many prospective motorists are awaiting the opening of the Exhibition to make up their mind as to the particular car they will select for their pleasures.

◆ ◆ ◆

Admission.

ADMISSION to the Exhibition will be one shilling, save on Wednesday, the 23rd, when the charge will be half-a-crown. The convenience with which the Agricultural Hall at Islington can be reached from any part of the great metropolis is well known and appreciated, both by provincial visitors and Metropolitan residents. A first-class band will be in attendance, and exhibitors are looking forward to much business in the few days the show will be open.

◆ ◆ ◆

Accumulators.

IN the course of a paper on electric accumulators read before the members of the Junior Institution of Engineers at Westminster Palace Hotel, London, this week, Mr. G. C. Allingham observed that the design of motor-car and other portable cells was still in a more or less tentative state, and was not standardised to anything like the same extent as was the case with stationary batteries. Light plates had a very short life. The general practice was to make them as cheap as possible, and simply scrape them and replace them by new ones as soon as they began to give trouble. Both positives and negatives were usually parted grids. They were made much thinner and placed much closer together than in stationary batteries. Generally they were something like one-eighth of an inch thick and an eighth of an inch apart. Sheets of ebonite or celluloid, corrugated and perforated, were usually placed between the plates. Something of the kind was absolutely necessary when they were so close together. The containing boxes were generally of ebonite, though celluloid was used a good deal for the smaller ignition and similar cells. The connections from cell to cell in motor-car batteries must be flexible and springy, else the vibration of the vehicle would cause the connecting lugs to break off.

The Use of the Stop Watch.

In dismissing a case against a motorist on Tuesday, the West London magistrate made a significant reference to the use of stop watches by the police which should be remembered by others who sit on the Bench. Although three policemen testified as with one voice, and produced a stop watch in support of their evidence, Mr. Lane was not satisfied with regard to the estimate of speed based on the stop watch. "Indeed," he said, "it was very liable to infirmity in the hands of persons who had not been trained to its use from their youth." After that the police authorities should either withdraw the stop watches, or put them in the hands of boys.

◆ ◆ ◆

Military Motor Trials.

In our issue of the 20th ult. some particulars were given of the trials carried out by the War Office in connection with the Stirling motor lorries at Edinburgh. These proved most successful, and on Monday next some officers of the Royal Engineers will start from the works at Granton Harbour to drive to London on the wagons, one of which is shown in the accompanying illustration. These motor lorries have four-cylinder petrol engines, developing 24-b.h.p. at about 800 revolutions a minute. They are fitted with mechanically operated inlet valves and solid cylinder heads. High tension

electric ignition with accumulators is fitted in addition to the magneto. The power is transmitted by a large metal friction clutch to a change speed gear giving three speeds, which are enclosed in a dust-tight oil bath. No chains are used, the rear wheels being driven by a universally jointed shaft to a driving bevel pinion which drives the countershaft, which is fitted with steel-toothed wheels engaging with driving rings made of a special metal attached to the inside of the wheels.

◆ ◆ ◆

Points for Exhibitors.

Some lessons from previous shows may well be learned by those who intend to take full advantage of the opportunities that will be presented for business at the Agricultural Hall. See that the attendants are fully instructed as to the technical points of machines, etc. Visitors nowadays are far more fully informed with regard to mechanical matters than was the case a few years ago, and betray a curiosity that is quite perplexing to anyone who does not really know what he is expected to explain. Exhibitors should also make a point of not over-crowding their stands with a wearying perplexity and complexity of exhibits. As in newspaper advertising boldness pays better than much confusion by over-crowding, so in exhibition displays it is not always well to overdo the thing with a too plentiful collection of any particular items.

Obstinacy in Wales.

While the East Ham, Ilford, and other London suburban district councils, which have already successfully established tramways, are now considering the question of putting motor-'buses on routes not served by such vehicles, some of the provincial municipalities seem to be possessed of a more narrow spirit. At Cardiff, for instance, the Cabs' Committee of the Town Council refused to grant licences to the South Wales Transport Company to run a service of motor-'buses between Cardiff and Llandaff, and Cardiff and Llanishen. On their minutes being brought before the full Council, however, the Chairman of the Tramways Committee moved that this suggestion be referred back, and after an animated discussion it was carried by a majority of three. Apparently some of the Councillors—loyal to their tramways—were quite heedless as to the convenience of the ratepayers in localities through which the tram-cars cannot possibly be run with any thought of profit.

◆ ◆ ◆

Variety in Decisions.

The other day Mr. J. Tofts was driving to the Bishop's Stortford railway station, when his horse shied at a motor-car that was standing stationary outside. The party was thrown out, and one of them subsequently died from concussion of the brain. At the inquest, the police-constable who gave evidence said that in his opinion the trap was being driven much too fast, and a verdict of "accidental death" was returned. We mention this as it is one of those rare cases where prejudice does not seem to have prevailed. In some parts of the country, the motor-car standing aimlessly still would doubtless have been regarded as the cause of this accident. Not long ago in Norfolk a horse shying at a motor-car standing on the road side resulted in an accident, and at the Assize Court the motorist was mulcted in heavy damages. What apparently is allowed in one county, is not regarded with favour in another.

◆ ◆ ◆

A Postponement.

Some idea of the interest with which the forthcoming Exhibition is regarded in automobile circles may be gleaned from the fact that not only are automobile organisations avoiding holding gatherings likely to clash with the official arrangements at the Agricultural Hall, but others which, like the Hertfordshire Automobile Club, had made their arrangements, are postponing their meetings so that their members may not be kept from the greater event. From the Secretary of this Club comes the note that "owing to the date of the inaugural run of the Hertfordshire Club clashing with the opening of the Agricultural Hall Show, it will now take place on Saturday, the 26th inst."

◆ ◆ ◆

Light or Heavy Vehicle.

From the evidence in a case heard at the Lambeth Police Court on Tuesday, it would appear to be customary among makers of road locomotives to weigh vehicles without their bodies, thus securing to customers the privilege of registration at the lowest fee. But, as we hinted in dealing with a kindred subject in our issue of the 6th ult., this will not avail should the authorities run the vehicles on to a weighbridge. Proof of this comes in the case referred to at Lambeth. A South London brewery firm was summoned by the London County Council for unlawfully using a locomotive in the county of London (in which county it was not licensed) without payment of the fee required by section 9 of the Locomotives Act, 1898. Mr. W. E. Helman-Pidsley, who supported the summons on behalf of the Council, said the Act of 1898 was known as the Heavy Locomotives Act, and applied to all locomotives used for haulage purposes which were over four tons in weight when unladen. Before a locomotive exceeding that weight could be used in the County of London a licence, which would cost £10, had to be procured from the Council; but if, on

Digitized by Google

the other hand, the locomotive was under four tons in weight unladen, then the Light Locomotives Act of 1896 and the Motor Car Act 1903 applied, and it simply had to be registered upon payment of a fee of £1. The firm took out a licence giving the weight of the engine as 2 tons 19 cwt. 3 qrs., but had excluded the weight of the body, without which it would be useless. The magistrate, in imposing a nominal penalty, said it was obvious that the weight of the complete vehicle must be taken.

◆ ◆ ◆

Mr. Jarrott on Drivers.

OUR correspondence on drivers has called forth many denunciations of the certificated person, and the mechanics seem to have been in the majority so far as letter writing is concerned. Now Mr. Charles Jarrott has been giving his view on the subject, and he mentions it as his opinion that the want of drivers is to be supplied by young men of serious intent, intelligent, sharp and bright. As time goes on, the requirements for drivers will become more and more exacting, and only those men who are capable of carrying out their work in an intelligent and satisfactory manner will be able to find places. The professional driver is one of the greatest difficulties the manufacturers have to deal with at the present time, and any movement to secure to owners of motor vehicles reliable men at once responsible, painstaking and law abiding, would meet with the greatest support from the trade. Naturally owners of cars will, in the future, prefer to engage only those who have obtained a certificate which will be giving some sort of guarantee as to their efficiency. This is a fact that we would advise mechanics who think of entering services as drivers to recognise, and urge them to equip themselves with the necessary theoretical as well as technical knowledge, or they may be left out in the cold by the greater popularity of those who have been through some sort of a course of construction.

◆ ◆ ◆

Motor-Car Upkeep.

To the discussion on the cost of maintaining motor-cars—a subject of almost continuous interest—the Scottish Club has made a useful contribution. As we report elsewhere, Mr. John Adam has been encouraging the members of that organisation to give their expenses. Ordinarily these have worked out at less than threepence a mile, to which, however, has to be added an item for depreciation. This question of depreciation is one which amateur motorists should not ignore. The depreciation of second-hand cars is much more nowadays than was the case a few years ago. Styles and methods are so transient that the fashion in automobiles is, apparently, becoming as fickle as in millinery.

◆ ◆ ◆

Motor-Car Houses.

ANOTHER practical point raised by Mr. Adam was in connection with the size of motor-car houses. Recently our Correspondence columns have contained letters from some hotel proprietors anxious to provide for the accommodation of motor-cars. For a single car Mr. Adam advises a house 18 feet by 9 feet with a pit 6 feet by 3 feet near the door. This, constructed of corrugated iron with wood lining, would, according to his estimate, cost £24. This would include placing a layer of felt between the corrugated iron and the wooden sarking. The matter is one upon which the views of readers this side of the Tweed might be useful.

◆ ◆ ◆

Pennington's Latest.

SOME of our American contemporaries to hand this week devote considerable space to the latest production of Mr. E. J. Pennington. Briefly summarised, one account is as follows:—"One of the most remarkable automobiles ever constructed is being built in the factory of the Eclipse Machine Company of Cleveland, O., for the Cleveland Motor Company. The last mentioned concern has recently been organised with an authorized capital of £40,000, to build high-powered touring cars to designs prepared by Mr. E. J. Pennington, who has a record on two continents as a promoter and inventor of unusual mechanical contrivances. The new car is 25 feet long and is equipped with motors which it is claimed will develop over 300 horsepower. Its inventor claims it will make 100 miles an hour, and to demonstrate his claim he proposes as soon as possible to place flanged wheels on the machine and give it a trying out on the rails of some steam or electric railway. The frame work is made of 4-inch heavy gauge tubing. The cylinders proper of the engine are of steel tubing, while the cylinder heads are turned from solid material. The cylinders are copper jacketed and are placed in the forward part of the frame, side by side in a horizontal position, being entirely independent of one another, although they drive on to the same crank shaft. In the centre of the crank shaft is a huge fly wheel. The road wheels are of steel, fitted with 7-inch pneumatic tyres. The front wheels are contained in steering forks closely resembling bicycle forks. The drive is by a heavy chain on to the rear axle." Those in this country who remember Pennington and his war motor vehicle, which was eventually knocked down for a song at an auction in Bloomsbury, will be entitled to a smile while reading the foregoing.

A Change at Newport.

THE recommendation of the Newport Watch Committee to limit the speed of motor-cars in the borough to ten miles an hour came before a full meeting of the Town Council on Tuesday, when the borough engineer pointed out that if the bye-law were adopted it would mean a large expense in putting up the requisite notice boards. Councillor Moxon urged that such a bye-law was needless, as they could always proceed against motorists who were driving in the streets to the danger of the public, even if only going at five miles an hour. There were only three other towns beside Newport that were proposing to adopt such a bye-law. At length it was resolved to refer the matter back for further consideration to the Watch Committee. It is to be hoped that common-sense will ultimately prevail.

◆ ◆ ◆

Motor Services about Dublin.

DUBLIN, which has so splendid a tram-car service, is shortly to be equally well favoured in regard to public services of motor-cars. Recently we chronicled the formation of a local company to run automobiles from the Irish capital to the suburb of Swords, and now the Liquid Fuel Engineering Company, of Edinburgh, have written to the Dalkey Urban Council stating that they propose to run a motor service from that pleasant suburb to Kiliney Park and Bray during the coming season. We are glad to hear that the Council has warmly approved of the idea, and the linking of Dalkey with Dublin by similar means should not be a difficult matter. There are several good routes which might be suggested about Dublin. The electric trams rush out to Clontarf and Howth rapidly enough for anybody, but a motor-car service to Lucan would be popular, and in other directions automobiles might be utilised with the certainty of a real Irish welcome.

◆ ◆ ◆

The Security of Numbers.

WE would utter a word of warning to car owners and the trade, that they should see that their numbers are so fixed that they cannot be tampered with. During the Crystal Palace Exhibition an exhibiting firm were running a car around the Palace, and garaged it with a number of others in a local livery stable. One day the driver had scarcely left the garage ere he was stopped by a policeman and then found there was no number on the front of his car. As some half-dozen others found themselves in a similar predicament, the occurrence could scarcely have been accidental. The sequel was a summons to appear at the Lambeth Police Court last week, and a fine of 5s. and costs. The suggestion has since been made that the numbers of private cars—which, when once registered, keep the number "for all time"—be, wherever possible, painted upon the car itself and not attached separately. With traders and manufacturers' numbers, which are changed about from car to car, this is not, of course, possible, but it will be well for all to see that the numbers are so affixed that it will be impossible to remove them without considerable trouble, or much inconvenience and injustice to drivers may result.

◆ ◆ ◆

A Motor-Martyr.

EVERY great movement has its Smithfield, and motoring has found a martyr-soul in the ranks of the Cumberland and and Westmorland Chamber of Agriculture. On the agenda of the last meeting was the item "the speed of motor-cars on district roads," and when it was reached Mr. Elliott moved a resolution to the effect that motor-cars being an innovation on the ordinary road traffic, owners and drivers should be held responsible for loss or damage caused by their use, seeing that no definite limit can be safely assigned to their speed of travelling on district roads. This was seconded, whereupon Mr. J. W. Hayton, of Carlisle, the secretary, pointed out that the resolution went beyond the notice on the agenda, and he should decline to forward the resolution to the Central Chamber of Agriculture. He spoke of the danger which motorists ran through cows being allowed on the roads unattended. He himself had a narrow escape from colliding with a cow which suddenly emerged from a farmyard to reach a watering place. Upon the resolution being adopted with only two dissentients, the secretary added, "Please take my month's notice." Of course, such an attitude opens up a wider question. Could not Mr. Hayton do good work for the automobile movement by remaining with the society and educating the members into a sensible frame of mind with regard to the inevitable motor-car?

◆ ◆ ◆

Delivery Vans.

THE A.C.G.B.I. have accepted an offer of a diploma from the Army Council for award to the motor vehicle which, in the motor delivery van trials to be held by the Club, is considered by the War Office Committee on Mechanical Transport to be most meritorous from a military point of view, and therefore likely to be of service, even though indirectly, to the Army. This is a department of automobilism that should come to the front during the present year and will largely predominate in future exhibitions.

◆ ◆ ◆

Valve Mechanism.

A PAPER on valves and the valve mechanism of internal combustion engines was read by Mr. R. E. Phillips at the Automobile Club last week. It contained a series of statistical tables of value and interest, and evoked a good discussion. Lieutenant-Colonel Holden presided, and after the debate summarised the proceedings. There could be no question, he said, that Mr. Phillips had given them a modification of the automatic valve which brought it up to the level—or nearly so—of the mechanically-operated one. With it the volume of the charge led into the cylinder must be larger, and therefore the compression would be increased and the power of the engine increased. They were also told that this improvement was obtained without any complication in adjustment, and that the valve was more certain to work properly; that was another great point. In connection with the data in the paper the thing that struck the speaker most was the extreme flexibility allowed in design in the internal combustion engine. It appeared that whatever was done it did not prevent the engine working; that, of course, was a great convenience for the manufacturers, but at the same time it ought to be a great incentive to them to find out by experiments, exhaustive experiments, what were the best proportions for their engines, and he would urge upon them the necessity of doing so. Regarding mechanically-operated valves in general, it was, of course, common knowledge that they were very old; in fact, all large gas engines had been made with them, and it was a puzzle to know why Daimler adopted automatic valves in his first engine. There could be no doubt the mechanically-operated valve had come to stay.

INCLUDED with the present issue is published, as a supplement, the index to Vol. V. of the *Motor-Car Journal*.

ON Saturday last the Derbyshire Club held its inaugural run for the present season, Ashbourne being the destination.

WE are officially informed that the statement made by a contemporary that the Queen has ordered a Wolseley car is not correct.

THE awards have just been published in respect to the recent trial of anti-skidding devices at Versailles. The highest number of points was secured by the Gallus arrangement of M. Edeline.

MR. WINDSOR T. WHITE, of the White Sewing Machine Company of Cleveland, makers of the well-known steam car bearing that name, has been elected president of the American National Association of Automobile Manufacturers.

Digitized by Google

THE CARE OF A STEAM CAR.

THE care of a steam car formed the subject of a recent lecture at the School of Automobile Engineering in connection with the Y.M.C.A. of Boston, to which reference was made in a recent issue. It was given by Mr. J. K. Macalman, manager of the local branch of the Locomobile Company, and as the author gave a number of hints which may be useful to those motorists owning Locomobile and similar steam cars, we print an abstract of the lecture below.

Confining our attention to the fire-tube type of boiler, to insure the maximum efficiency of this type a certain amount of care is necessary. When first firing up and the steam-gauge begins to show a pressure the blow-off valve should be opened to let a small quantity of water be discharged through the same. When the water begins to boil, the sediment, which is settled on the bottom of the boiler, is disturbed and begins to rise. By means of the blow-off valve more of the impurities can at this time be removed than at any other.

When the steam reaches 50 or 60 lb. this sediment settles back and is not easily disturbed. If these impurities are allowed to remain on the bottom of the boiler, they form a non-conducting hard scale, covering the plates and lower ends of the tubes, which interferes with rapid steaming, and in addition removes the protection of the water directly in contact with the flame. The cleansing of the boiler removes to some extent the liability of burning it, as this is too often caused by sediment clogging the circulating system, which includes the check valves on the water column or gauge glass.

The water in the gauge should fluctuate with the motion of the car, and when found to remain stationary it is an indication of clogging. This can be remedied by tapping the check valves and opening the water column gauge until the sediment is cleaned out. The sole indication of the amount of water in the boiler is the water in the gauge, and it is absolutely necessary that the driver makes sure of perfect circulation.

To obtain uniform steaming capacity, the fire must be able to meet the varying demands. This regulation is commonly secured by the so-called "automatic," which consists of a needle valve actuated by the steam pressure on a diaphragm, the valve closing as the pressure increases to some set point and shutting off the fuel supply. Care should be taken that the packing of this valve is neither too tight nor too loose, as in the former case it fails to work promptly, and in the latter is liable to leak and thus destroy the whole efficiency. Another source of trouble is the cracking or breaking of the diaphragm, which should be at once replaced.

The fuel system should be cleaned out occasionally in the following manner:—Open the torch valve and let a small quantity of cold petrol through under high pressure. This will soften and remove a portion of the scale and grit and thus prolong a free flow of petrol. The jet valve on the automatic should be cleaned out from time to time. This may be done by unscrewing the jet valve spindle and removing the small plug opposite the jet nozzle. Take a small piece of wire and clean the scale out thoroughly, as when the jet becomes in any way plugged it interferes with the air mixture, does not produce a good fire, and sometimes causes the burner to fire back.

The type of steam engine commonly used necessitates proper lubrication of all moving parts. This lubrication is divided into two sections: One where the steam is in direct contact with the movable parts. For this a special grade of oil is essential, one that will not burn or be disintegrated by the heat. Only enough oil should be fed to form a mixture with the steam and keep the surfaces coated, and to permit the engine to start easily and without undue grinding or squeaking. In the other section—the external parts—the oil distributed should be of a consistency to prevent its quickly running off. It is not necessary to have oil dripping from every portion of the engine, a little will perform the same work and there will be no waste. Cleanliness is to be strictly observed, and the engine should be washed from time to time with kerosene to remove the extra oil and grit.

Before starting a car, after steam is up, the driver should open the throttle slightly and move the car slowly backward and forward. This will warm up the engine and drive out the water formed in the cylinders by condensation. This is very necessary, as the pressure of the steam acting on the water will often cause bursting of cylinder heads, stripping of bolts, bending or breaking of connecting rods, and blowing out of piston packings. These same results are sometimes caused by too much water in the boiler, so that, instead of steam being fed to the engine, water boils over and enters it. This is evident from the blowing sound of the exhaust and the diminution of power, and is commonly called priming.

From time to time the rear wheels of the car should be jacked up and the engine run slowly, the action of the various parts of the engine being closely watched. All reciprocating parts should be kept in adjustment, and a trial as above mentioned will permit of accurately locating needed adjustments. The pumps and check valve can be thus tested. Check valves should be reground from time to time. This can be determined by an examination of the valve faces, which should be smooth and bright.

The burner is often blamed for inefficiency when the trouble is really in the air mixture and fuel feed, and often a poor burner is benefited by some means of covering it or giving it more air, as the case may require. When the burner fires back the cause may be traced to various reasons—sometimes the mixing tube is not properly adjusted or the jet valve is not in the right position. This can only be ascertained by trying the different ways to discover the cause.

Experience fails to show any easy way of repairing a boiler on the road. Putting oatmeal or some cereal in the boiler to find the leak and stop it from the inside has been suggested, but is not recommended, as it is almost impossible to get these substances out again.

The only way to repair a burned boiler is to carry along the proper expanding tools. Having the tools on hand, it is necessary to stand the carriage on end and remove the burner. If the burn is slight, the bottom may be caulked without removing the top hood. After doing this one can tell whether the boiler is tight or not by using the hand water pump and filling the boiler with water, pumping it until the steam gauge shows a pressure of about 300 lb., and if it will remain at this point one can conclude that the boiler is tight. Unless, however, one is an expert in this class of work, it should be placed in the hands of a competent repairer.

THE Japanese Government have placed an order with the Olds Motor Works for twenty Oldsmobile railway inspection cars. The vehicles, which are of 5-h.p. and run on rails, seat four passengers each.

MESSRS. ALFRED DUNHILL, LIMITED, have brought out a pneumatic cushion which does away with vibration. It can easily be inflated with an ordinary foot pump, and can be covered with leather, pegamoid, or other suitable material to match the upholstering of the car.

THE Beaufort Motor Company have sent us a copy of the new catalogue they have issued. It gives full particulars and illustrations of the 9-10-h.p., 10-12-h.p., 15-19-h.p. and 24-30-h.p. Beaufort cars. No less than sixteen pages are devoted to testimonials from users of these well-known cars, a fact which speaks much of their popularity.

FROM The Maudslay Motor Company, Limited, comes a copy of their 1904 catalogue, in which full particulars are given of the 18-h.p., 25-h.p. and 40-h.p. Maudslay cars. Diagrams are given of the company's three-cylinder engine, in addition to very clear illustrations of the wagonettes, touring cars, double tonneau, etc., made by this concern.

CONTINENTAL NOTES.

THE Danish Automobile Club sends us a French translation of the automobile regulations enforced in Denmark, from which the following is extracted:—Motor vehicles must not differ essentially either in size or appearance from horse-drawn vehicles serving similar purposes. Motor vehicles serving for goods transport or to carry more than six persons, if not provided with rubber tyres, must have tyres at least 4 inches wide. Every motor-car must be provided with two separate braking systems, each capable of stopping the vehicle within 12 yards; each vehicle must be provided with a signal horn and must carry at night two lamps provided with colourless glasses and of such luminous intensity as to light up the road for 15 yards ahead of the vehicle. Motor-cycles must carry one such lamp. In addition each vehicle must carry a lamp to illuminate the registration number.

ALL automobile vehicles must be registered with the proper authorities, the formalities being essentially the same as enforced in France. Motor-vehicles can only be operated by persons in possession of a driver's certificate issued by the local police authorities, and the driver must at all times carry the certificate with him when driving his vehicle. Persons under eighteen years of age are not allowed to drive automobiles; the same applies to drunken persons. The most peculiar provision of the law is that from July 16 to May 15, inclusive, automobiles are not

A Snapshot near Abbazia, Austria.

allowed to be driven on the public highway between one half hour after sunset and one half hour before sunrise, except where the road is thoroughly illuminated by artificial light. The Minister of Justice may, however, waive this rule for certain departments or districts upon the recommendation of competent counsel. The maximum speed allowed in towns and villages is 9·4 miles per hour, and on the public highways 18·5 miles per hour. At night the speed must not exceed 9·4 miles per hour in any place. Foreigners who wish to tour with their cars in Denmark must declare their vehicle at the police headquarters of the first town they enter. In case they are provided with a driver's certificate issued by some foreign authority it suffices to present this and have it indorsed by the police authorities; otherwise a special certificate will be made out for them.

THE Bordeaux Automobile Club is organising an "automobile week," to be held from the 8th to the 15th May next. It is proposed to hold a competition of commercial motor vehicles, a balloon race, and an exhibition.

THE international motor-car exhibition to be held in Frankfurt-am-Main from the 19th to the 27th inst. promises to be a most successful affair, the list of exhibitors already comprising over 150 names.

THE Portuguese "Diario do Governo" of the 22nd February contains a notice calling for tenders, which will be opened at 1 p.m. on the 24th May next, in the Directorate of the Caminhos de Ferro Ultramarinos, Lisbon, for the exclusive concession during fifteen years for running automobiles for the transport of persons and merchandise from Mossamedes to Chibia, in the Portuguese Colonies.

THE Commission du Yachting Automobile of the A.C.F., at its meeting on the 20th ult., decided that the 1904 race for motor-boats shall take place on Monday, August 8th, about ten o'clock in the morning, starting from either Calais or Boulogne and finishing at Dover. The entries for the race will be closed on June 30th, and the entry fee will be 100 francs for boats up to 20 ft. 6 in. (8 metres) inclusive, and 200 francs for boats of greater length. With this race the Coupe Recope will be competed for without a special entry fee (this cup is for boats using ordinary petroleum) and the Coupe Quinones de Leon for boats using denaturalised alcohol, with a special entry fee of 200 francs. That is to say that owners of boats who wish to compete for the Recope Cup or the Quinones de Leon cup alone, without being entered in the big race, will have to pay, in the first case, the entrance fee for the race according to their class, and for the second the fixed sum of 200 francs. The French Minister of Marine has officially promised to convoy the boats by torpedo boats on leaving the French coast, and it is hoped to obtain a special prize from the Department. It is also suggested that the Automobile Club de France should allot the sum of £800 to be distributed in prizes for this race.

IN connection with the German winter military manœuvres at present being held in the Harz, trials are being made with two motor-cars for the transport of officers, two motor-wagons and a couple of motor-cycles.

A NOTICEABLE feature of the automobile movement in Germany at the present time is the increasing attention which is being paid to the question of connecting small towns, not served by railways, by public services of motor-cars. Several have recently been established, while a number of others are in contemplation. The municipal authorities of Langenschwalbach have voted a sum of £150 towards a public service of motor-cars between the town and railway station which a syndicate proposes to establish at an early date. A motor-omnibus service is also projected between Lindenfels and Bensheim, while a service for the conveyance of both passengers and goods is also about to be started between Brunswick and Wandsburg.

ARRANGEMENTS for the motor van and wagon trials, which will take place from August 22nd to September 4th, under the auspices of the A.C.F., are being rapidly pushed forward. The programme has now been issued, from which it appears that there will be a section for speedy delivery vans, with a carrying capacity of less than two tons, another for heavy wagons carrying more than two tons, and a third for electrically-propelled tourist cars. The first and second days' programme will be made up of consumption tests in Paris, which will be continued on the 12th and closing day of the trials; the intervening days will be taken up with road trials, with an exhibition at Lille on the seventh day.

LA SOCIETE DES DESSINATEURS DE L'INDUSTRIE AUTOMOBILE is the name of a new society which has been formed in Paris. There are now a good many well-qualified automobile designers and draughtsmen in France, and it is hoped that the new association will be the means of bringing them together for the interchange of ideas.

THE newly-formed Lake District Road Traffic Company intend running a motor service between Windermere and Keswick for both passenger and freight traffic. A piece of ground has been secured in the centre of Ambleside (near the old Market Cross), where offices for the company's use are to be erected.

SOME USEFUL NOTES.

SOME very useful "Hints for Motorists" have lately been issued by the Hozier Engineering Company, Limited, from which we take the following, as, while primarily intended for users of Argyll cars, they apply equally well to many other well-known types of gear-driven vehicles:—Lubrication is one of the most important points in the running of a motor; neglect on this score may result in very serious consequences, most probably a total break down of the engine. Ordinary gas engine oil should be avoided, being quite unsuitable for high speed engines. Oil of a very high flash point and free from deposit at high temperatures is the most suitable. With the pump system of lubrication it is preferable to oil often and in small quantities; half a charge every fifteen to eighteen miles will be found to give the best results. With the drop feed system the lubricators should be set to give from five to six drops per minute for each cylinder.

◆ ◆ ◆

AFTER each day's run it is advantageous to inject a teaspoonful of paraffin into each cylinder of the engine and give the motor a few sharp turns by hand; this will remove all "gumminess" from the cylinder walls and prevent the piston sticking. After about 500 miles' running, remove the sparking plugs and wash the engine out thoroughly by injecting about a wineglassful of paraffin into each cylinder; after turning sharply by hand for a few minutes remove the plug from bottom of crank case and allow all the waste oil and paraffin to drain off completely. Before starting the engine again it will be necessary to put about half a pint of lubricating oil into the crank case of a single cylinder engine, three-quarters of a pint into a double cylinder, one and a quarter pints into a three cylinder, and three pints into a four cylinder. This may easily be done through the examination hole in the crank chamber. The air regulator of the carburettor should not be altered after it is properly set; the engine starts more easily on a rich mixture, this can be attained by slightly flooding the carburettor.

◆ ◆ ◆

SHOULD there be a loss of power in the engine the following points should be examined for the cause: leakage at either the exhaust or inlet valves, sparking plug, or piston rings, weak accumulators, dirty sparking plug, imperfect contact at the contact breaker, caused by a weak spring in the contact arm, or by carbonised oil on the fibre disc and contact pieces, or burning of the platinums on the trembler of the induction coil. The latter may be cleaned by removing the screw and trembler blade, and dressing up the contact pieces perfectly square to ensure good contact when replaced. Put on the switch, put the contact breaker in position to close the circuit, then adjust the screw to the blade till the most violent vibration of the trembler is attained. Lock the screw in position by means of the locking nut. When making this adjustment it is most important that the sparking plug wire should be connected to the plug and the plug to the cylinder; should this be neglected there is every probability of the coil being injured by burning.

◆ ◆ ◆

SHOULD misfiring occur, examine the sparking plug points, to see whether they are clean and the proper distance apart (about $\frac{1}{32}$ of an inch); see that the porcelain of the plug is not broken, all terminals of the wiring properly tight and clean, contact breaker clean and proper adjusted, accumulators not under four volts and all parts of the wiring, which are likely to come in metallic contact with the framework, properly insulated. A most successful method of finding a short circuit is to put the car in the very darkest place obtainable and start the engine, when any leakage in the electric circuit will be easily found, a dull blue flicker showing up bright in the dark although quite imperceptible in the light. Do not discharge the accumulators below 3·8 volts. Although it is possible to run on less than this it is most injurious and shortens the life of them. Examine the accumulators frequently to ascertain whether the top of the plate is well covered with the electrolyte; if the top of the plate is visible add only pure distilled water to cover it.

IT is advisable to run off about a cupful of petrol from the carburettor end of the petrol pipe about once a fortnight; this will clear away any water that may have gathered. The petrol in the carburettor should also be allowed to run off. The carburettor should be taken down and thoroughly cleaned out about every three months; it must be kept clean and free from water or grit.

◆ ◆ ◆

IF the clutch should "slip" it will be due to oil getting on the face of the leather. This should be washed off by pouring petrol through the hole in the friction clutch drum or fly-wheel, a little fuller's earth may be applied afterwards. The clutch should not be allowed to slip for any length of time, as the heat generated will burn the face of the leather; when this takes place it is best to have the leather replaced at the first opportunity. Remember to regularly oil the friction clutch bearing. Don't give more than a few drops, as when too much oil is given it will find its way on the leather face of the clutch.

◆ ◆ ◆

A CHARGE of oil should be given to the gear box about every 200 miles, and all the actuating levers should be kept well lubricated and working freely, so that the gear can be changed without any "sticking" in any of the joints. As it has been fully demonstrated that the wear and tear of the gear box is almost always all due to bad manipulation, it is of the utmost importance that drivers should make certain that they have acquired the knack of changing gear without jar or noise. To change, the left foot pedal should be depressed, and the change immediately made by the hand lever; no force is necessary, but the lever should be quickly and lightly moved from one notch to the other. The gear should never be changed from a high to a lower speed until the car is moving at approximately the rate of the lower speed.

◆ ◆ ◆

WHEN descending steep dangerous hills, the Hozier Company recommend that the descent be made on the second speed, or even the first speed, if the hill is very dangerous. In this way the car cannot run away, and the brakes are reserved for any emergency. Of course, ordinary hills can be descended with the engine running free. Never allow the car to get out of control, but always know that it can be stopped immediately, if necessary. The brake power provided is more than ample, but it should not be abused. When driving in the ordinary way allow plenty of time to stop, as sudden application of the brakes is sore on the mechanism, and should only be done to save accidents.

◆ ◆ ◆

THE back axle should have a charge of solid oil about every 500 miles, by means of a force pump supplied for the purpose. A charge should be given to the gear and also to each of the axle tubes through the screw plug holes. The front wheels may be very efficiently lubricated with grease, the outer cups should be filled up, and by screwing these home the grease will be forced right through the bearing. The steering gear should be oiled every 100 miles. All the mechanism of the car should be kept clean, and all joints regularly oiled.

A REWARD is offered for the number of a dark motor-car containing three men in white peaked caps, which killed a dog between South Mymms and Barnet on Sunday, the 28th ult. about 3.30 p.m.

AN echo of the Reliability Trials of Septenber last comes in a letter dated March 3rd by the Technical Secretary of the A.C.G.B.I. to Messrs. Mann and Overton's, Limited, in which he says that on inquiring into the climb of Westerham Hill by the car No. 106 in the Trials he finds that the Observer made a mistake in his notebook in booking the car as having stopped on Westerham Hill. The Observer was not, apparently, acquainted with Westerham Hill, and booked a stop which occurred on a hill previous to Westerham as occurring on Westerham Hill itself. The marks for both Georges Richard cars, numbers 57 and 106, on this hill stand good, and in the amended certificate the marks are duly entered.

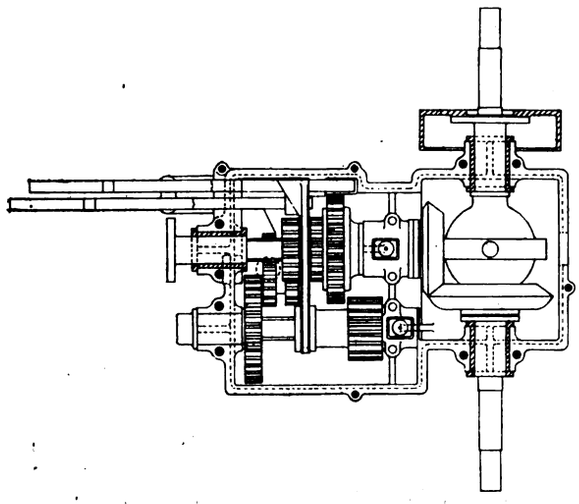
THE "SUNBEAM" SIX-CYLINDER CAR.

WE gave a general description of the new six-cylinder "Sunbeam" car of Messrs. John Marston, Limited, in our issue of the 6th ult., while in that for the 27th ult. we gave drawings of the metal-to-metal friction clutch employed on the vehicle. We are now able to illustrate the engine and gear box of this interesting car. Figs. 2 and 3 represent respectively an end elevation and a part longitudinal section of the 16-18 h.p. motor. As will be seen, the six cylinders are cast in three



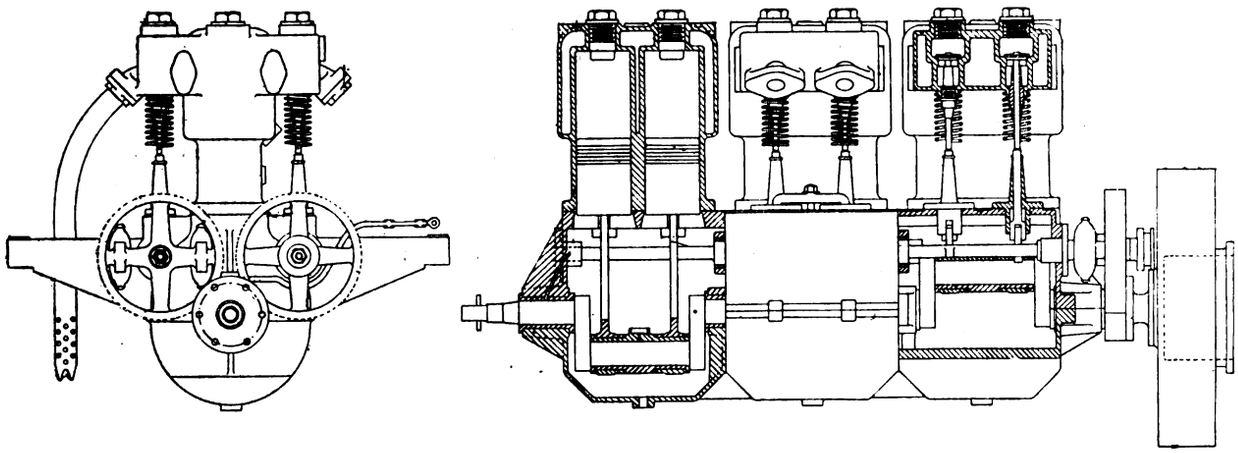


Fig. 1.—Sectional Plan of Change Speed Gear Box on "Sunbeam" Six-Cylinder Car.

pairs. The bore and stroke are the same as in the "Sunbeam" 12-h.p. car. The pistons of each pair of cylinders work on their own crank, the cranks being set at an angle of 120 degrees. The valves are all mechanically operated, the inlets being on the opposite side to the exhaust, and are interchangeable as far as valve seats, plugs, guides, etc., are concerned. A new feature is embodied in the inlet valve cam shaft, which is made so that the cams can slide longitudinally, they being sloped off towards the back, thus providing a variable lift to the inlet valves, giving a large range of control of the engine speed, at the same time effecting a notable economy in the quantity of petrol consumed. There is, of course, beyond this the ordinary throttle governing device. Fig. 1 shows a sectional plan of the gear box, which provides two forward speeds and a reverse with a direct drive on the top speed.

Figs. 2 and 3.—End and Part Longitudinal Section of "Sunbeam" Six-Cylinder Motor.

Two Napier cars will be on view at the motor-car show in Boston, which opens on the 14th inst. These will be the first cars of English manufacture to be shown at a public exhibition in the United States.

WHY WAIT?

FROM the very beginning of automobilism there has always been a number of persons who have announced themselves as firmly determined to buy a car some day, but who have been waiting, and are still waiting, for what they consider a "perfect" motor vehicle. Of course, many who express such sentiments are not sincere, and are merely endeavouring to disguise an inability or a disinclination to expend the price of a good automobile, but undoubtedly there are others who are actually waiting in good faith for the coming of their ideal vehicle. Their idea is that some wonderful system will be brought out which will render all present machines fit only for the scrap heap, and so they wait and wait, missing years of enjoyment, for the car which never comes.

As a matter of fact there is very little probability that the car perfect in equipment and satisfactory in price will ever come, and there is nothing in the history of other important inventions, such as the bicycle, the sewing machine, or the many applications of electricity, for example, to warrant any such expectation. In almost every case the differences between the earliest models and those of the present day are comparatively unimportant, and while many improvements have increased the efficiency and modern methods of production have lowered the prices of the apparently perfected article, the fundamental principles of operation have remained the same. Similarly as regards the automobile, it is the general opinion of well-known constructors and others best qualified to judge that the lines on which future development will take place are already well defined.

The tendency is not for startling innovations, but rather for taking existing systems and gradually improving them, as experience shows that such action is advisable; but even this process must be very gradual. If an improvement be thought of to-day to a standard pattern engine or gear made by any good firm, it will probably be nearly a year before it will be embodied on the cars turned out by the particular makers, as it will be tested carefully, and possibly modified a dozen times before its final form is decided. These things are being continually done by the manufacturers, remarks a writer in the "Automobile Magazine," but the automobile world never hears of them, as many changes which appear to be very promising are found in the long run not to be improvements, and are discarded, possibly to be taken up again a few years later, and found wanting once more, by some other experimenter. This is the history of other mechanisms, and it will be found that all the most successful and practical have been gradually evolved in this way.

The would-be automobilist may therefore safely go ahead and purchase the car which best meets his requirements among existing models, with a certainty that no revolutionary inventions will make it obsolete before he receives an adequate return on his investment.

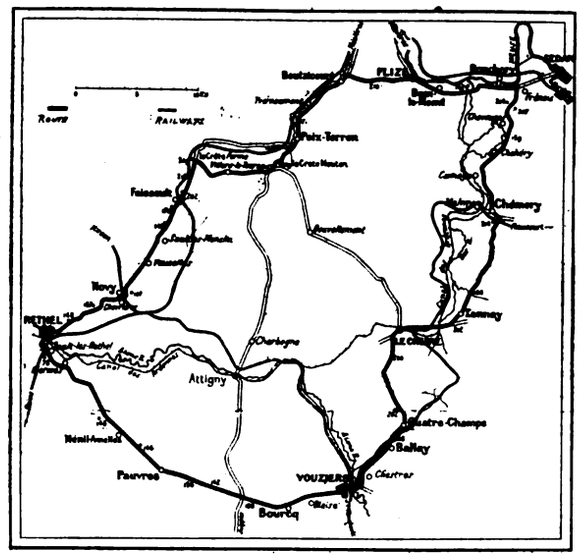
THE GORDON BENNETT RACE.

THE prospect of the eliminating test for the Gordon Bennett Race being held in the Isle of Man is one which will be regarded with pleasure by all interested in the development of British sport. At one time it seemed probable that the British eliminating test would take place in the Ardennes, but the rapacity of the Burgomasters of Belgium caused the officials of the English Club to look for another course. Mr. Orde has been in the Isle of Man, and has apparently found a road which will be suitable for the purpose. This is certainly an advance upon the way in which the trials were conducted at Welbeck last year. As we pointed out at the time, it seemed rather absurd to select the drivers for a contest of close upon 400 miles on the strength of the speed attained over a kilometre course. However, now we have the promise of something like a genuine test, and the fact that it will be held on English soil should make it an event of primary importance to British motorists, who may be expected to invade Mona in even greater numbers than they rushed into Ireland last year. Let us hope that the hotelkeepers of the Island will prove themselves as modest as their *confreres* in the Emerald Isle showed themselves exorbitant in their charges.

THE rules and regulations for the eliminating trials which will probably be held in the Isle of Man during the latter part of April, are of interest at the present moment. All cars intended for competition must be produced for inspection at the Automobile Club, Piccadilly, W., by noon on Saturday, April 16. Each firm entering shall contribute at the rate of £50 for the first car and £25 for each succeeding car towards the cost of the trials. Each entry must be accompanied by a deposit of £250–this deposit to cover any number of cars entered by any one firm. Unless the car (or cars) presented for the selection trials conforms (or conform) in all respects with the requirements of the Gordon Bennett rules, and unless the car is, in the opinion of the committee of the club, a *bona fide* racing car suitable to compete in the Gordon Bennett race, the £250 will be forfeited. If a car entered is not at the appointed place by noon on April 16th, 1904, the deposit of £250 shall be forfeited and shall remain in the possession of the club. After the selection trials, three cars and drivers and reserve cars and drivers shall be chosen by the club, it being understood that, contrary to the rules governing the eliminating trials of 1903, the selection trials of 1904 are held simply for the guidance of the club in making their choice, and the winners of the selection trials will not necessarily be selected to represent the club in the race. The names of the proposed drivers must be submitted to the committee of the club before the inspection of the cars, and the committee shall have the right to refuse any driver at their discretion.

THE programme of the Gordon Bennett week has now been definitely fixed as follows:—

June 16th.—Weighing of the competing cars.
June 17th.—The Cup race.
June 18th.—Tour over the course and dinner at Homburg.
June 19th.—Track races at Frankfort-am-Main.
June 20th.—International Automobile Conference at Homburg.
June 21.—Elegance Competition and Flower Fete.



IT is said that there is still plenty of hotel accommodation to be had at Mainz, which is only twenty-five miles from Homburg. The municipal authorities of Mainz are reported to be willing to provide two buildings to serve as garages during the Gordon Bennett week, each having accommodation for about 200 cars.

NO authoritative announcement has yet been made by the Committee of the Automobile Club of America as to the time and place of the eliminating trials for the American team. The Secretary of the Club has been commissioned to make an investigation of the Virginia beach, near Norfolk, and report on its fitness as a place for holding the trial tests.

THE course finally chosen for the eliminating trials for the French Gordon Bennett team, and for which official sanction has now been given, is shown in the accompanying map. It is in the French Ardennes, the exact course being shown below:—

	Kil.		Kil.
Rethel	0	Donchery	65
Sault-les-Rethel	1	Dom-le-Menil	70
Biermes	4	Flize	73
Menil-Annelles...	10	Boulzicour	78
Pauvres	16	Poix	86
Bourcq	27	Cretes de Poix	87
Vouziers	32	Neuville-aux-Tourneurs ...	92
Ballay	37	Cretes de Neuvisy	97
Quatre-Champs	40	Faissault	103
Le Chesne	48	Saulces-Monclin	110
Tannay	51	Novy	116
Chemery...	59	Rethel	125
Chehery	60		

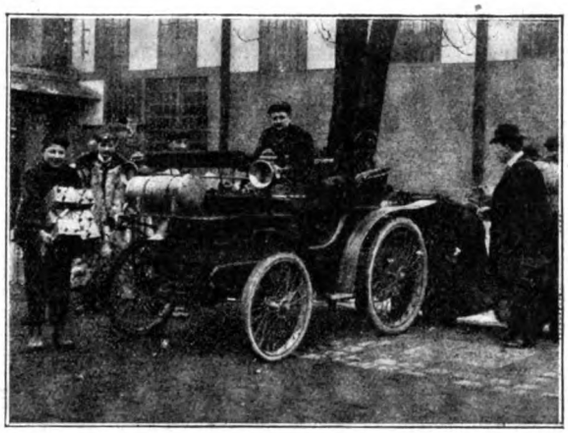
The exact distance is 78 miles, and will therefore have to be covered four times. Most of the places named are villages in which there will be no difficulty in making precautions for the public security, while the course is so good that the cars will probably be able to attain higher speeds than will be possible on the Gordon Bennett course. At the same time there are hills at Poix and Neuvizy which will sufficiently test the speed of the cars on gradients.

The course of the French Eliminating Trials. [*L'Automobile.*

FRIDAY, May 20th, has been fixed for the French eliminating contest, the weighing-in to take place on the 19th of May. The competitors will draw lots for the order of starting, in the following way. The car of the competitor who secures No. 1 will start 1st, 11th, and 21st, the one who secures No. 2, 2nd, 12th, and 22nd, No. 3, 3rd, 13th, and 23rd, and so on. No ladies will be allowed to drive in the French team.

THE colours of all the competing nations have now been fixed; they are as shown below:—

Germany, white.	Belgium, yellow.
Great Britain, green.	Italy, black.
France, pale blue.	Austria, black and yellow.
United States, red.	Switzerland, red and yellow.



REGARDING the reference to their garage in South Street, Newcastle-on-Tyne, in the last issue, Messrs. George and Jobling ask us to mention that their establishment is just one minute from the Newcastle end of the High Level Bridge, and that in a short time their garage will be always open, and connected with the outside world by telephone.

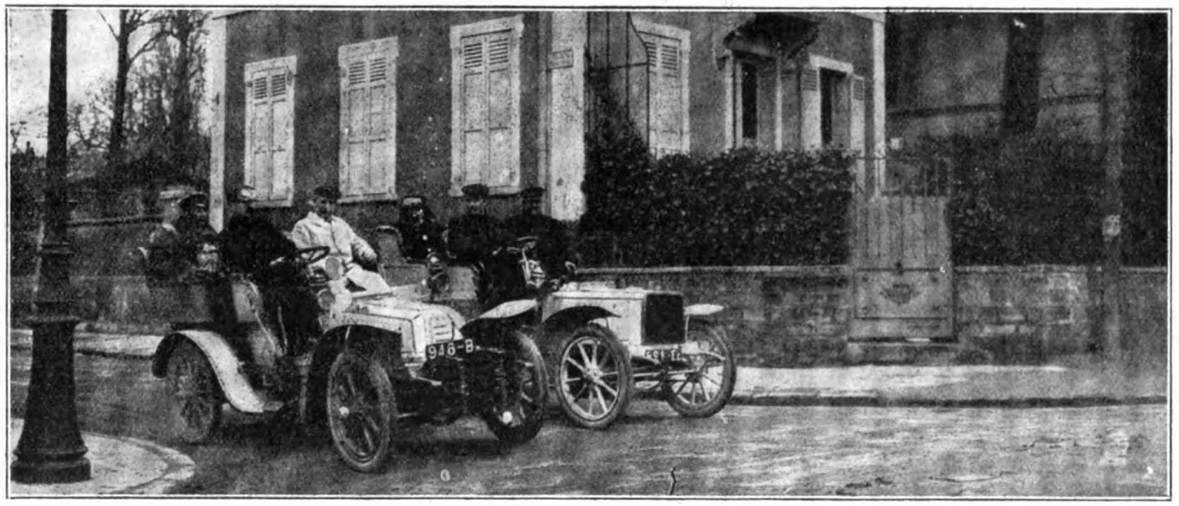
THE FRENCH CONSUMPTION TRIALS.

THE fourth annual "Criterium de Consommation" organised by "L'Auto" commenced on Thursday last week. The competition was divided into the following classes:—



Passenger cars costing less than 5,000 francs.
" " from 5,000 to 8,000 "
" " " 8,000 " 12,000 "
" " " 12,000 " 18,000 "
" " " 18,000 " 25,000 "
" " " 25,000 " 40,000 "
" " over 40,000 "

The Chenier-Lion (Peugeot) Car, which utilises Paraffin, Shale Oil, Naphthaline as Fuel.

The Peugeot Lorry.

The Two Successful Creanche Cars in the Criterium de Consommation.

Lorries carrying less than 1 ton.
" " over 1 "
Delivery vans carrying less than 500 kilos.
" " from 500 to 1,200 "
" " over 1,200 "

The points taken into account in the trials were: The consumption of fuel, the average speed and regularity of running, and the hill-climbing capabilities. Thursday the 3rd inst. was devoted to a 100 kilometre run from Suresnes to Corbeil and back by the pleasure cars costing less than 12,000 francs. Points were allotted to each competing car as follows:—1. Consumption per total weight, the marks being equal to the number of litres of fuel consumed, divided by the weight of the car and its load, in tons, multiplied by the co-efficient ten. 2. Consumption per useful load, marks equal to litres consumed divided by useful load in tons multiplied by ten. (3) Any car averaging less than 25 miles per hour was given marks equal to the difference in kilometres between its average and that required multiplied by twenty-five. (4) On the hill climb on Picardie Hill a speed of 30 kilometres per hour was required. Any lower speed secured marks equal to the difference between it and 30 kilometres multiplied by five for the outward journey, with flying start, and by ten for the return trip, standing start. Seventeen cars competed, all getting back within the specified time. The car entered by Messrs. Chenier and Lion excited much interest, it being an old Peugeot fitted with two-cylinder horizontal engine, but adapted by the inventors to use either paraffin, napthaline, shale oil, or petrol as fuel. On the first day paraffin was used. The following are the results:—

Classification.	Car.	Weight of Car and Load. Kilos.	Total Consumption. Litres.	Total Marks Allotted.
	Class I.—Chassis less than 5,000 francs.			
1.	Peugeot	875	5·600	511·1
2.	Peugeot	775	5·420	512·4
3.	Fouillaron	1,000	9·130	602·9
4.	Noe Boyer	785	5·080	878·9
4.	Bolide	975	12·950	878·9
6.	Roy	900	13·940	951·9
	Class II.—Chassis from 5,000 to 8,000 francs.			
1.	Creanche	1,130	7·630	356·8
2.	Chenard Walcker...	1,210	8·560	589·2
3.	Vivinus	1,040	12·	635·
4.	Vinot-Deguingand	1,315	11·430	677·4
5.	Aries...	1,185	13·550	753·6
6.	Creanche	1,038	10·880	839·5
7.	Boyer	1,618	15·750	842·5

Digitized by Google

Class III.—Chassis from 8,000 to 12,000 francs.				
1.	Creanche	1,300	9·770	507·
2.	Aries...	1,402	10·210	517·4
3.	Vinot-Deguingand	1,383	18·100	796·5
	Heavy Oil.			
	Chenier-Lion	1,168	14·810	—

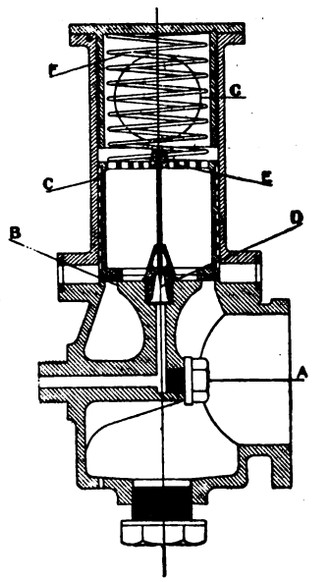
On Friday, the 14th inst., the cars costing from 12,000 fr. upwards were submitted to a trial over the same route. On this day the Chenier-Lion car used shale oil as fuel. Appended are the results of the first cars in each section :—

Number.	Car.	Weight of Car and load Kilos.	Total Consumption Litres.	Total Marks allotted.
	Chassis costing from 18,000 to 25,000 francs.			
1.	L'Automotrice	1,638	14·700	553
	Chassis costing from 12,000 to 18,000 francs.			
1.	Peugeot	1,650	14·700	475·5
	Shale Oil.			
—	Chenier-Lion	1,145	12·170	937

The commercial vehicles were put to the test on Saturday, they being required to cover a sixty kilometre course to Longjumeau and back, the Chenier-Lion car taking part in the procession, with naphthaline as fuel. The same rules regulated the proceedings, except that only an average speed of fifteen kilometres and twelve kilometres on Picardie Hill was required. The table below gives the results :—

Classification.	Car.	Weight empty, Kilog.	Load. carried, Kilog.	Total consumption, Litres.	Marks allotted.
	Class 1.—Heavy Lorries.				
1.	Peugeot	1,680	3,000	16·110	186·97
2.	Bardon	1,730	1,313	16·670	364·38
3.	Gillet-Forest (heavy oil)	1,476	1,504	17·400	452·4
	Class 2.—Light Lorries.				
1.	Gillet-Forest	737	787	10·680	380·1
	Class 3.—Delivery Vans Carrying less than 500 kilos.				
1.	Aries	963	322	7·350	285
	Class 4.—Delivery Vans carrying more than 500 kilos.				
1.	Gillet-Forest	880	570	9·500	372·7
	Napthaline (in balls).				
1.	Chenier-Lion	1,230	230	6 kilos.	

It will be seen that the Peugeot Company headed the lists in three of the classes and the Creanche Company in two of the categories.



"AUTOMOBILE TOPICS," of New York, informs its readers that "at the Crystal Palace automobile show, in London, several cars belonging to King Edward were shown"!

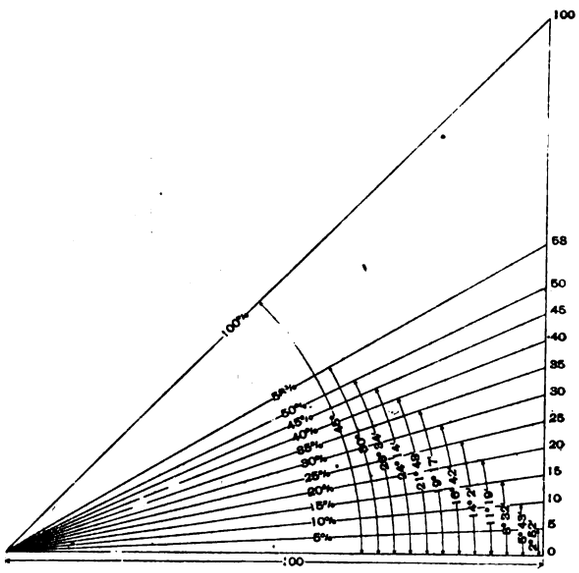
IN connection with the race for motor-boats which is being organised by the A.C.F. to take place on August 8th next, from Calais to Dover, the A.C.G.B.I. is taking steps to obtain Admiralty sanction and the co-operation of the various railway companies, municipalities and yacht clubs to make the race a great international success.

THE Automobile Club of America will hold in the week beginning April 4th an international trial of motor-wagons, open to all used for commercial purposes. The classification will be on the basis of dead load carried, all wagons of like weight, whether steam, petrol, or electric, to operate in the same class. The following classes have been established :—(1) To carry a dead load of 1,000 lbs. or under; (2) 1,000 to 2,000 lbs.; (3) 2,000 to 3,000 lbs.; (4) 3,000 to 4,000 lbs.; (5) 4,000 to 5,000 lbs.; (6) 5,000 to 6,000 lbs. With a view to holding a more thorough and practical test than has hitherto been afforded, the wagons will be placed under actual working conditions in the service of the American and Westcott Express companies, and will deliver merchandise, produce, etc., from the various stations of these companies for an entire week. Awards will be made in each class for the best performance, based on the economy of operation in time and fuel, ratio of paying load, ton mileage and general reliability and availability for service.

THE CHENARD-WALCKER AUTOMATIC CARBURETTOR.

IT is a well-known fact that the carburation changes with the speed of the motor, and that the mixture (which should remain constant, by which is meant those proportions of air and petrol vapour which give the best explosion, and therefore maximum influence), alter to a very marked degree, resulting in a considerable loss of efficiency. In order to overcome or rather to rectify these variations it has hitherto been necessary for the driver, in order to obtain the best results out of his car, to continually devote his attention to the regulation of the gas and air levers, usually found situated on the steering columns. As this adjustment could only be effected, even by the most expert *chauffeurs*, in a more or less perfunctory manner, it follows that it was seldom that a motor was working under the best conditions suited to its requirements at the moment. Several more or less successful attempts have been made in the past to get

Section of Chenard-Walcker Carburettor.



over this difficulty by carburettors which automatically take in a supplementary supply of air when the same is required. Messrs. Chenard and Walcker have devised and are fitting to their 1904 car a new automatic carburettor which is claimed to give a perfect mixture for all engine speeds. The accompanying illustration gives a sectional view of the carburettor, the float feed being omitted. The air which enters at A has to pass the annular entry B, which is opened and closed by the movable valve C. Attached to this valve is a conical needle, D, which controls the feed of petrol in direct relation to that of the air. F is a spiral spring, exerting a slight constant pressure on the valve, and G is the outlet of the mixture to the motor. Let us now examine what happens when the motor is working. As soon as the suction from the motor exceeds the tension of the spring, the valve lifts, opening the annular air ring and the petrol supply in their correct proportions; the greater the speed, the greater, naturally, the suction, whilst at the same time the valve lifts higher in consequence of the increased suction opening the air and petrol orifices in the requisite proportions for correct mixture. A number of claims are made for the new carburettor, among which may be mentioned the following :—It economises fuel, as the maximum impulse is derived from each charge. It simplifies driving, since there are no air or gas levers to attend to, and even in starting, as well as on the road, the existence of the carburettor can be entirely ignored. It renders the car remarkably silent, while, having no mechanical complications, and depending merely on the laws of nature, there are no parts to wear out and nothing to go wrong.

THE MEASUREMENT OF GRADES.

THERE is considerable misunderstanding current as to the method of measuring road grades and a general tendency to over-estimate the incline of hills. The matter, however, is a very simple one. Grades are usually measured on a percentage basis, and this percentage is the ratio of the vertical distance climbed to the length of the horizontal distance travelled. A horizontal base line is assumed originating at the commencement of the incline, and all grades are referred to this. If a perpendicular is erected to this horizontal line, the distance along it from its base to the point where it intersects the grade itself is the rise. The ratio of this vertical rise to the length of the base line from its beginning to the foot of the perpendicular is the measure of the grade. Of course, the ratio of the difference in height between two neighbouring perpendiculars, to the horizontal distance between them, is the measure of the grade. If two perpendiculars be chosen 100 feet apart and one of them be 20 feet and the other 30 feet in height, the rise in the 100 feet of horizontal distance is 10 feet and the grade is one of 10-100 or 10 per cent.

If the incline is not uniform, it is necessary to choose the perpendiculars closer together than 100 feet in order to obtain the per cent. of grade with sufficient accuracy, for it is simply the average grade between the perpendiculars which is obtained by

this method. In the accompanying diagram a horizontal base line has been drawn, and grades of percentages varying by 5 per cent. stages up to 50 per cent. have been represented by inclined lines radiating from the left hand end of the base line.

It is very common to find people confounding the percentage of a grade with the angle of incline which it makes with the horizontal. The angles corresponding with each percentage of grade here represented are marked upon the diagram for purposes of comparison. It will be seen that the percentage of the grade increases in an entirely different ratio from the angle of slope, and, in fact, the per cent. of grade is simply the natural tangent of the angle of incline. A grade which makes an angle of 30 degrees with the horizontal is equivalent to a 58 per cent. gradient. A 45 degree slope is equivalent to a 100 per cent. grade, or, in other words, the vertical distance is equal to the horizontal distance. The usual cause of the almost universal over-estimation of gradients lies in the fact that when looking up a hill the length of the road itself is greatly foreshortened, while the vertical distance is projected at its full value. This causes the apparent ratio of the vertical distance to the horizontal distance to be greatly exaggerated and leads to the estimation of the per cent. or the angle at an excessively high value.

In rolling country, where one is constantly descending and ascending hills, the incline which one is approaching is likely to be over-estimated on account of there being no horizontal base line at hand to assist in the estimate. One is likely to unconsciously assume the down grade upon which one may be as horizontal, and thus its decline is added to the incline of the rise which one is approaching. About the only condition under which one can make even a fair approach to accuracy in the estimation of a grade is, remarks a writer in the "Horseless Age," by viewing it from a point at right angles to the length of the road and from a horizontal surface. This condition is seldom realized.

The gradometers which are on the market consist of a spirit level which is made in the form of an arc, lying in a plane along the length of the car. The gradometer should be attached so that its base is level when the vehicle is horizontal. The bubble should then stand at zero. In ascending or descending a hill the bubble moves in the appropriate direction along a scale which is graduated in per cent. The accuracy of the readings of gradometers is somewhat affected by the loading of the vehicles upon which they are placed.

THE NICE WEEK.

PREPARATIONS are well in hand for the automobile *fete* to be held at Nice from the 22nd to the 30th inst. On the 22nd and 23rd inst. there will be a touring competition; on the 24th inst. a gymkhana, followed on the 25th inst. by a *rallie papier*, or automobile paper chase. On Sunday, the 27th inst., there will be a procession of decorated cars. The races commence on Monday, the 28th, by a series of mile trials, followed by the flying kilometre trials for the Henri de Rothschild Cup. On Tuesday, the 29th inst., there will be a *concours d'elegance*, at Monte Carlo, while a kilometre hill-climb on the Corniche road will take place on the 30th inst. if the necessary prefectural authorisation can be obtained. Some new records are expected to be created in the various events, for among the entries so far received are the following:—

Baron de Caters	90-h.p.	Mercedes.
Warden	,,	,,
Jenatzy	,,	,,
Braun	,,	,,
Werner	,,	,,
Andrew Fletcher	,,	,,
Mark Mayhew	80-h.p.	Napier.
S. F. Edge	,,	,,

A CHARGING plant has been established by the Motor Mart, Limited, at their premises in the Euston Road.

WE understand that motorists anxious to obtain an early number for their cars can secure this by registering their vehicles in Argyllshire.

MESSRS. DEASY AND COMPANY are very shortly moving their depot from Piccadilly to 10, Brompton Road, close to Tattersall's, Albert Gate, S.W. The new premises will allow sufficient room for carrying on repairs under personal supervision.

THE United Motor Industries, Limited, have sent us a sample of a specially delicate yet pure grease for placing on the terminals of coils and accumulators to prevent the damp getting to them, and to keep them perfectly clean and satisfactory for ignition. This grease has been devised by M. Boulanger, the electrical expert, and manager of Messrs. Bassee and Michel, and is being introduced into this country by the United Motor Industries.

THE exclusive agency for the productions of Messrs. Charron, Girardot and Voigt, makers of the well-known C.G.V. car, has been secured by the London Motor Garage Company, Limited, who can deliver from stock C.G.V. cars of 15-h.p. and 25-h.p., with *chassis* of standard length, or of larger dimensions to admit of side entrances. The company have appointed Mr. Charles Joiner, who has been connected with Messrs. Charron, both at the works and sales departments, for five years, as manager of their business.

HERE AND THERE.

A STEAM 'bus is now plying for hire at Eastbourne.

MR. J. R. STATHAM is opening a garage in the High Street, Kilkenny.

MR. H. S. VANE has been appointed secretary to Messrs. S. F. Edge, Limited.

THE accompanying illustration represents the new six-cylinder Duryea petrol engine which has been specially built for

use in an air-ship, in which extreme lightness has been aimed at. It will be seen that the two sets of three cylinders are opposed. The valves, as in the new British-made Duryea engine, are in the head, the inlets being automatically operated. The cylinders, which have a bore of 4½ in. by 5½ in. stroke, are of cast iron, and the crank shaft is a hand forging bored hollow to reduce weight. The engine, complete with water jackets partly filled with water and everything ready to run, weighs 232 lbs., and develops 40½-b.h.p. at a speed of 900 revolutions per minute, giving the effective result of 5.7 lbs. per h.p., a noteworthy advance in lightness of construction which reflects much credit on the builders, the Duryea Company, of Reading, Pa., U.S.A.

A WELL-KNOWN motorist fined at the West London court for driving a car without a rear light made a strong appeal to a magistrate not to endorse his licence, and succeeded in avoiding that awkward witness to his waywardness.

THE Reading Automobile Club, the Oxford and District Automobile Club, the Sheffield and District Automobile Club, and the Eastern Counties Automobile Club have joined the Motor Union under scheme II., which provides for affiliation at a fee of 5s. per annum.

INQUIRIES recently made by the U.S. House of Representatives concerning the number of vehicles of all kinds maintained at Government expense are said to have disclosed the fact that the United States Government owns only one automobile. It is an electric vehicle used principally in carrying the mails to and from the Bureau of Standards, located in the suburbs of Washington.

"LA LANGUE ANGLAISE SANS MAITRE" is the title of the latest volume in the "Self-Taught" series issued by Messrs. E. Marlborough and Company. This will be useful to all Frenchmen learning English. One result of the development of automobilism has been the increase of the value of a knowledge of languages other than their own to a good many people. Some of the automobile expressions might have been less literally translated than by the author, Mr. Thimm, but on the whole the work is freer from solecisms than most books of the kind.

AN automobile club has lately been formed in Kiew, Russia.

LAST Saturday the Herefordshire Automobile Club held a run to Abergavenny.

MESSRS. ALLSOPP AND SONS' motor-car for the use of their travellers is a 9-h.p. Beaufort phaeton.

A NEW list of more than six hundred agents for the Vacuum Mobiloils has just been issued by the Vacuum Oil Company, Limited.

THE Motor Van and Users' Association is now in full work, the first committee having been elected. Mr. W. Rees Jeffreys is secretary

AT the new technical institute which the London County Council have established in Saltram Crescent, Paddington, a motor-car workshop is to be started.

A FIRE broke out the other day in the motor-car house of Mr. C. D. Leng, of Sheffield, who was unfortunate in losing not only his motor-car house, but the two cars it contained.

EVERY car owned by a maker or agent, and intended for sale, must bear the identification mark assigned by the registering authority of his district. In no case must this exceed £3.

OWING to the alleged excessive size and brilliancy of the lights used on motor-cars in Dorset, the Dorset County Council has decided to ask the Local Government Board to limit the power of the lights.

Where all Motorists will be flocking on the 19th inst.

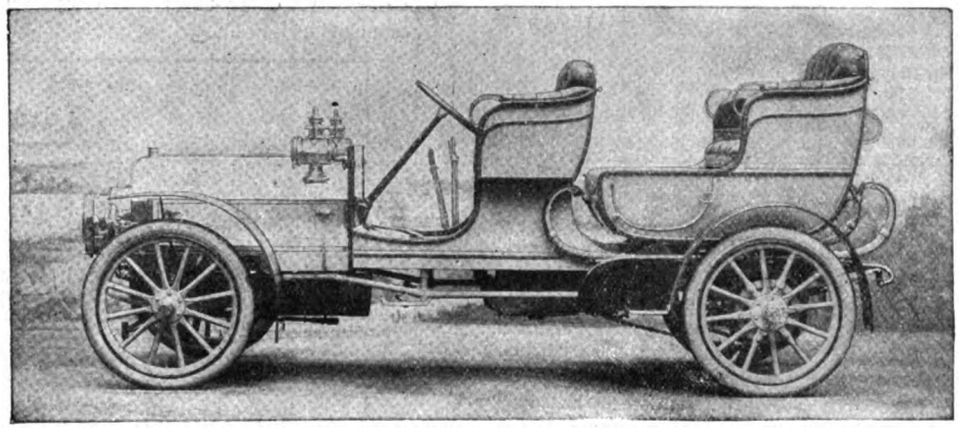
THE Planet "Peerless" sparking plug has a glass-cased jump spark attachment, and acts in grease and soot equally as well as if clean. It is being placed on the market by the Automobile Engineering Company.

MESSRS. W. HUNT AND COMPANY, of Kettering, have brought out a non-skidding device consisting of two discs or wheels to bite on the road inside the road wheels at option of the driver. When not in action they are automatically released and raised clear of the road.

Digitized by Google

MESSRS. JULIUS HARVEY AND COMPANY have just shipped a steam motor-wagon and six trailing vehicles for use on mining properties abroad.

THE Kennedy Motor Company, Limited, has been registered with a capital of £10,000 and offices at Newlands Road, Cathcart, Glasgow.



AT the annual meeting of the Dutch Automobile Club, held a few days ago, it was announced that the list of members now comprised 204 names.

AS already mentioned in these columns, there is every probability of the British eliminating tests for the Gordon Bennett race taking place in the Isle of Man.

MR. EDWARD CORNET, motor-car agent, of Thornhill, N.B., will shortly be opening a garage at Dumfries, where he will stock accessories and undertake repairs to motor-cars.

"LA FRANCE AUTOMOBILE" in a recent issue refers mysteriously to a new clutch for motor-cars which is expected to cause a sensation when it makes its appearance on the market.

ONE of the striking features of modern automobiles is the great advance which has been made by carriage builders. As an example of the luxurious bodies now being turned out, we herewith illustrate a four-seated side-entrance car, known as a "berceau," the design of M. A. Belvalette, a well-known Parisian carriage builder. It is mounted on a 20-h.p. Gobron-Brillié *chassis*. As will be seen, the rear portion is separately carried on its own C springs, entire freedom from vibration being claimed as the result of the special suspension.

A Gobron-Brillie Car with Belvalette "Berceau" Body.

THE "Criterium de Consommation" organised by the "Auto" commenced on Thursday and concluded on Saturday, last week. Altogether forty-two entries were received for the event, the results of which are given elsewhere in the present issue.

KEENE'S AUTOMOBILE WORKS, LIMITED, has been registered with a capital of £10,000 to acquire the business of Keene's Automobile Works; to adopt an agreement with Mr. H. Perry Keene; to buy, sell, repair, alter, let on hire, store, and deal in motors, motor-cars, cycles, carriages, and vehicles, &c. The first directors are Messrs. H. L. A. Perry Keene, C. F. H. Harrison-Watson, J. Urlwin, and C. Young.

MESSRS. A. AND C. BLACK are issuing a series of volumes on the country scenes associated with the lives of the great names in literature. The associations of Scott and Burns have already been described; now comes a new book by Mr. C. G. Harper on the Ingoldsby country—that delightful corner of Kent peopled by the wonderful legends of the Rev. R. H. Barham. The motorist who wishes to explore the district with the definite object of tracing the developments of Ingoldsby's genius as well as of seeing the pleasant landscapes and coast scenery with which his humour was identified, should take Mr. Harper's chatty volume, with its delightful pen and ink sketches, as a "guide, philosopher, and friend."

THE Earl of Norbury has ordered a 4-cylinder Craig-Dörwald car.

THE Medway Motor and Engineering Company, Limited, will open an up-to-date garage on the 25th inst. at 77, High Street, Chatham.

THERE are now nearly 100 automobile clubs in North America, the latest organized being the Motor Car Club of Nova Scotia, Halifax, N.S.; the Newton Automobile Club, Newton, Mass., and the Automobile Club of New Hampshire.

IN our report of the Langdon-Davies Motor Company's exhibit at the Crystal Palace we referred to the change-speed gear under their own name. In order to prevent any confusion we are asked to mention that the gear is known as "Soame's."

MR. ANDREW CARNEGIE is having built a three storey fireproof motor house at No. 55, East Ninetieth Street, New York, at a cost of £4,000. It is to be twenty-five feet front and thirty feet deep, provided with a lift and living quarters on the upper floors.

JAMES ROBERTSON was fined 10s. at Marlborough Street, London, for "unlawfully exhibiting an advertisement on a motor car" in Hyde-park, contrary to the Park Regulations Act. Robertson said he did not know that he was committing any offence by going into the park. Nobody said anything when he entered, so he had no idea that he was contravening the regulations.

THE Continental Caoutchouc, Continental Patent Tyre and Guttapercha Company are calling special attention to their motor tyre canvas bag, which has the advantage of keeping tyres clean from mud and water whilst travelling. It does not expose the rubber direct to the sun's rays when attached to the car, and will also prove very handy when sending a cover by rail.

THE use of alcohol as a fuel for combustion engines in automobiles in the United States seems to be an early possibility, a Bill providing for untaxed denaturized alcohol having been introduced into the House of Representatives by the Hon. Henry S. Boutell, of Illinois. The Bill provides for the sale of alcohol free of internal taxes, with penalties for removal of the substances which are added to make the alcohol unfit for use as a beverage.

FROM the Hozier Engineering Company, Limited, comes a copy of the 1904 catalogue of Argyll cars—one of the finest productions of the kind that has so far reached us. A few pages are devoted to a description of the Hozier works, after which follows a very complete description of the various features of the Argyll cars, diagrams being given of all the principal parts, such as the three-cylinder engine, clutch, change speed gear, brakes, etc. The nine pages at the end of the list devoted to testimonials from users of the Argyll cars form an excellent indication of the popularity of these vehicles amongst the motoring public.

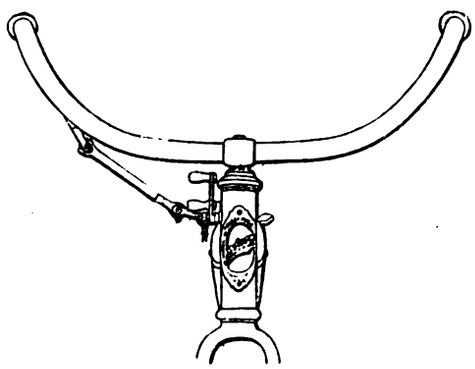
MOTOR-CYCLING NEWS.

THE forthcoming trials promoted by the Auto-Cycle Club to test the various non-slipping devices for motor-cycles will be watched with great concern by those who are interested in this form of motoring. The trials will take place on a private track which has been specially prepared with some slippery material, such as clay, etc., and these tests will be followed by a run of not less than 500 miles in order to gauge the durability of the devices. Entries close to-day (Saturday).

THE new catalogue just issued by the Rex Company, Coventry, contains instructions as to how to operate the Rex motor-cycles. The diagrams of the working parts are lucidly drawn and explained, and should be of great service alike to users of this machine and to those who contemplate its acquisition.

THE Garrard Manufacturing Company, Limited, have lately introduced a neat ladies' motor-bicycle. As will be seen from the accompanying illustration, it resembles in appearance an ordinary pedal-driven machine with dropped frame, while the forks are the firm's own special anti-vibration type. The motor is of 1½-h.p., fitted with spray carburettor, and driving the rear wheel by means of a twisted raw-hide belt. The machine is controlled by one lever fixed on the handle-bar. The

tanks are two in number, one being placed between the upper and lower tube members near the steering column, the other behind the seat pillar tube. The engine is supported in a vertical position well in front of the bottom bracket, and a shield is fitted over the belt.

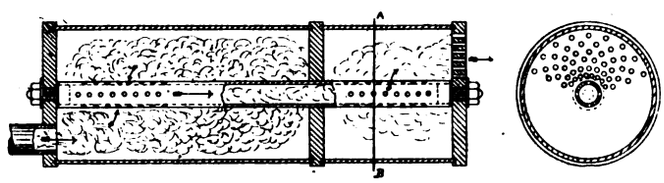


THE German Motor Cyclists' Union, of Stuttgart, has decided to hold a competition of lamps—acetylene, oil and electric—for motor-cycles in April next. Unfortunately it has been resolved to restrict the competition to German makers.

EVEN in India the motor-cycling movement is making progress, as is evidenced by the fact that a motor-cycle club has lately been formed at Delhi.

NINETEEN entries have so far been received for the reliability trial for motor-bicyles from Paris to Bordeaux and back, which is to be held by the Autocycle Club de France from the 22nd to the 27th April next. Any British makers of motor-bicycles who intend competing should apply at once to M. C. Doué, 38, Rue Amelot, Paris, as the competitors entered before the 15th inst. will ballot for starting positions, while those entering after that date will start according to their entry number.

AN International motor-bicycle 100-kilometre competition will be held in May next at the Porta Salaria Velodrome, in Rome. The King of Italy has given a gold medal to be awarded to the winner of the event.



AN American firm of motor-cycle builders, the Hendee Manufacturing Company, of Springfield, Mass., are bringing out for the 1904 season a machine which is entirely controlled by one hand, so rendering it unnecessary for the rider to remove his hands from the handle-bar. By a mere "twist of the wrist" on the right grip, not only is the speed increased and decreased at will, but it also lifts and drops the exhaust valve

and makes and breaks the electrical circuit. The device consists of a flexible shaft connected with the right grip, leading down inside the handle-bar to universal joints and a telescoping shaft which connects with the speed lever on the head of the machine. The construction is stated to be very simple, and admits of perfect steering with the front wheel. In all cases the lever control fixed to the top bar of the machine will be retained, so that in case of accident to the handle-bar of such a serious nature as to break the bar or affect the grip control, the lever may still be used for the purpose of controlling the engine.

THE annual meeting of the Birmingham Motor-Cycle Club was held on Saturday, being presided over by Mr. R. Tingey, chairman of committee, who was supported by Messrs. E. H. Humphries (captain), L. C. Davis (vice-captain), and J. R. Bedford (hon. secretary). During the evening a letter was read from Mr. C. Jarrott offering a silver cup to the member of the club who, during the present year, covers the greatest distance in twenty-four hours on a motor-bicycle or motor-tricycle. The only stipulation is that the time of the trial shall be twenty-four hours on end, with the view of seeing what distance can actually be covered in the time, not with the idea of abnormal speed, but more in the shape of a touring competition, no speed beyond the legal limit of twenty miles an hour average to be recognised.

MESSRS. COXETER AND SONS, LIMITED, of Abingdon, have recently brought out a new silencer for use on motor-cycles, of which two sectional views are given herewith. It consists of a cylinder divided into two compartments, through both of which extends an iron tube, pierced, as shown, at both ends. The exhaust gas enters at the opening at the left and expands in the first large

chamber; it then passes through the holes in the tube, and, travelling along the latter, emerges and further expands in the right-hand compartment, from which it passes to the atmosphere through the openings in the cap. It is claimed that by means of the device the exhaust is rendered perfectly silent without causing any back pressure on the engine, which is thus able to develop its full power. The silencer, which is readily detachable for cleansing purposes, measures 8 in. in length by 3 in. diameter.

CORRESPONDENCE.

BENZ v. LIGHT CAR.

To the Editor of *The Motor-Car Journal*.

Sir,—Your correspondent, G.L.B., suggests that owners of the more powerful Benz cars should give their experience of them. I have used a 6-2-h.p. Benz (tonneau) four-seated car in my practice and for touring since December, 1902, and it has given me the greatest satisfaction. The engine is wonderfully reliable and can always be depended on to get you home again. I can average from eighteen to twenty miles per hour on a run with four up, and it has never yet refused to carry its load up any hill. The cost of upkeep and repair has been very moderate, in spite of the fact that I have used it regularly in all weathers and given it some hard work.

The solid tyres supplied with the car were much too narrow and small altogether, and, being a square shape, tore off. I have replaced them with much broader rounded tyres and now have no trouble in that respect. I have also had the silencer placed further back, near the rear axle, and the engine, which used to get rather hot, now keeps cool. The workmanship throughout is sound and good, and I have yet to hear of a better four-seated car at the price. It is a matter of wonder to me that we hear so little of the more powerful Benz cars in this country and that they are never entered for the trials. Certainly they are very different machines to the wretched little three-and-a-halfs that one sees rattling and clanking about year after year as though they would never break up or wear out.—Yours truly,

Doctor.

To the Editor of *The Motor-Car Journal*.

Sir,—Your correspondent "Solid Tyre" suggests that there must be many "Benzites" who can testify to the good qualities of the geared Benz car, and as he mentions belt transmission and those who condemn it. May I just give my experience with the 4½-h.p. geared Benz.

I fitted a Dick's patent belt, which I bought for a few shillings some ten months ago; this has only been off for adjustment once during this period. I should like to mention, for the benefit of your readers, that for a 4½-h.p. engine the belt should not be less than a five-ply one and should be joined with the screw and stud fastening.

With regard to tyres it is only necessary to test the resiliency of the carriage springs fitted to these cars to be convinced that pneumatics are in reality a secondary consideration as compared with the proper springing of the carriage body. One other useful tip to Benzites—don't use the sparking plug as supplied by the makers but have the existing plate on these threaded to take a De Dion plug. In this case the plate need not be removed when fitting a fresh plug in, and, again, the cost is less. Considering the reliability and the long life of these cars, it is somewhat a matter of regret to hear that the firm have given up making them and are turning their attention to heavy cars only.—Yours truly,

Benz the Third.

STEAM v. PETROL.

To the Editor of *The Motor-Car Journal*.

Sir,—I notice "Searchlight" is asking for advice *re* steam *v.* petrol. should certainly advise steam, as there is nothing like the wear and tear in a steam car that there is in a petrol vehicle; no gear box wear and tear, no lightning speed of the engines, no carburettors, nor the thousand and one things you would have with a petrol car. I am using a Locomobile steam-car, which I have been running for two years, during which time I have made many alterations, which have improved the running of the car. I have removed the condenser, and coupled the exhaust to the three-way cock, so that I can turn the steam into the water tank, which does away with the water heater, or when required I can exhaust under the car. I know some critics will say the oil I lubricate with will get into the tank, then the boiler. I say, into the tank, but not the boiler; as the oil will float on the water, all that is required is to wash the tank out occasionally. By this means you are saving some weight, and allowing yourself more room to get around the engine. I have also substituted a steam lever tap for a wheel valve, which is a saving in the chain drive, as the engine starts much steadier, and saves jerking and straining the driving chain. Then I changed the petrol burner for a Clarkson paraffin burner, which saves much in fuel, and when I take my car out I do so in confidence of bringing it back again, or rather the car bringing me back. I have had twenty years' experience of steam-engines, namely, locomotives, steam cranes, steam navvies, winding engines, etc., and if I wanted a dozen cars now, they would all be steam.—Yours, etc.,

Steamer.

MOTOR-CAR REPAIRS.

To the Editor of *The Motor-Car Journal*.

Sir,—Undoubtedly your correspondent "Chirurgeon" is right to a certain degree *re* motor-car repairers (?). Many of the above so-called "repairers" are cycle agents who are gaining their experience at the cost of both the manufacturer and owner of the car they pull about (*repair*). On the other hand, no encouragement is given to practical men to open repair shops in local towns. Take the following instance:—Some time since an owner of a car told me there were several gentlemen in his district running cars, but it was almost impossible to get any repairs done without sending to the makers for a man, there being no reliable man in the district. I then made the following proposal:—That a small limited company be formed for repairing and garaging cars in the district; the various owners of cars to find half the capital between them, and I to find the other half, and take charge of the garage at a small salary. The above appeared to me to be a reasonable proposal, but no one would take it up. I have had a long practical experience in various makes of cars, and had my proposal been adopted, it would have been to the mutual advantage of the car owners and myself. As things are at present, really good men will not risk their money in opening repair shops in strange towns without any local interest.—Yours truly,

Engineer.

To the Editor of *The Motor-Car Journal*.

Sir,—I think it would be a good thing if there was some way of having our accounts looked over by some responsible firm to see into overcharges. In regard to the account about which there has been some correspondence, can you inform me if I can send the statement to someone and have it corrected, as I do not object to paying a fair charge; in fact, I have paid already one half of the account, and would like to know how much, if any, I am really owing. Some of your readers will, perhaps, kindly inform me upon this, and help me out of the dilemma. I consider "Francois'" suggestion a good one, as there ought to be some means of registering proper workmen.—Yours truly,

Chirurgeon.

CLEAN VALVES.

To the Editor of *The Motor-Car Journal*.

Sir,—I have a two-cylinder car. On taking out one inlet valve I notice it and its exhaust valve are sooty. The other inlet and exhaust valves are quite clean. Why is this?

Is it safer to drive with the clutch pedal disconnected from the pedal brake? In my car they are connected, so that I cannot put on the pedal brake without declutching.—Yours truly,

W. A. W.

PARAFFIN CARBURETTORS.

To the Editor of *The Motor-Car Journal*.

Sir,—There seems to be a good deal of interest centred round the relative merits of petrol and paraffin, and carburettors for paraffin. Perhaps, with your permission, Mr. D. J. Smith, or any other user of the Trusty carburettor, would be kind enough to give us a sectional sketch of the apparatus, and explain its working. There are a good many excellent carburettors on the market at present, and there must be something extra special about this one to fit it for paraffin. Is it necessary to employ a heat jacket with it?—Yours truly,

Cycle Mechanic.

TIMING GEAR TROUBLES.

To the Editor of *The Motor-Car Journal*.

Sir,—In answer to a query by Mr. H. Brown, in your issue of the 27th ult., I would like to say that I experienced a similar incident as far back as the winter of '98-'99. The firm I was then working for did the repairs for a public service company, who used the 6-h.p. Daimler type of engine (to carry fourteen passengers). I had to put in a new rocker in the semi-rotary pump, which had been broken by trying to start the engine with the pump frozen up. The driver, I believe, came from doing a milk round straight on to driving the car. However, after a good deal of unprofitable "winding up," it was found that the two to one gears had jumped a few teeth when the ice crushing was going on. The distance which an overhung gear wheel will spring without giving a permanent "set" to the shaft is very often considerable, especially if the shaft is made of high-class steel.—Yours truly,

Ad Sum.

THE YORKSHIRE CLUB.

To the Editor of *The Motor-Car Journal*.

Sir,—With reference to the paragraph in your issue of the 5th inst. on the authority of Mr. A. W. Dougill, stating that the Yorkshire Club has a large number of members in Bradford, Harrogate, Halifax, Barnsley, Bridlington, and Sheffield, this statement is apt to mislead one into the notion that they have a large number of members in Sheffield, which city can boast of a very live automobile club of its own, viz., the Sheffield and District A.C., which has a membership roll of 110, and which includes in its district Rotherham, Barnsley, Doncaster, Chesterfield, and North Derbyshire, whereas the Leeds organisation can, I believe, boast one Sheffield member. This gentleman joined them before the local club was formed. Last year they had two, one of whom was a member of both the Yorkshire and the Sheffield Club, but he left the district some time ago.—Yours truly,

Fred B. Cawood, Hon. Secretary,
Sheffield and District A.C.

FROM A CRITICAL READER.

To the Editor of *The Motor-Car Journal.*

Sir,—I read your *Journal* every week with interest, but sometimes your enthusiasm on behalf of motorists and all things connected with them rather amuses me. For instance, a few weeks ago I read that the Staffordshire county authority had taken about £247 in fees under the new Motor Car Act, and you hoped they would use it properly towards improving the roads. As the Staffordshire County Council already spend about £40,000 a year on their main roads, I am wondering what great improvement you expect for the extra £247.

Another thing I suggest that you should publish a list of motor-car repairers and their addresses.—Yours truly,

D O. 12.

[Does D.O. 12 suggest that the roads of Staffordshire are so perfect that they cannot be improved? The point of the suggestion was that fees obtained from motorists should be utilised on some work likely to be of benefit to them—the provision of signposts and the improvement of the roads naturally occur at once in such a connection. So far as the list of motor-car repairers is concerned we would refer our correspondent to the small advertisements headed "garages" and to the intimations which are published in our literary pages weekly.]

QUERY *RE* NEW GEAR DRIVE.

To the Editor of *The Motor-Car Journal.*

Sir,—We would take it as a favour if you would kindly allow us to reply to the query in your last week's issue, as we fancy many of your readers may be labouring under the same misconception of what has been termed the worm drive to the live axle of motor-cars, or, to use enquirers' own words, "That it seems clear that one could not 'coast' unless the back axle was fitted with a free-wheel device of some sort." This is not so.

Maybe if it could be looked on as a helical or skew tooth drive, its reversing would be better understood; this is really what it is, and when properly made and case hardened, with the spiral lead of the worm tooth leaves or wings (which are usually seven in number) being equal to their circumference at the pitch line for giving an angle of 45 deg. makes the gear not only very high in efficiency, but practicable as driver or driven.

When this type of drive becomes better understood there will be no doubt of its having many more friends. Although "Live Axle" makes reference to the Dennis and Hitchon-Weller, some credit is due to the Lanchester Co. for their persistency in forcing the opposition to this drive so long, and as testimony of their experience they exhibited at the recent show a gear of this type which has run 5,000 miles with no appreciable signs of wear.—Yours truly,

Hitchon Gear and Automobile Company.

BELT-DRIVEN CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—Can any reader tell me where I can obtain Dick's canvas belting? I see this is highly spoken of in some of the back numbers of the *Journal* I have been using leather belting, which does very well for the high speed, but on the low speed I find it slips a lot unless the engine is going slowly. Is there any belting made which will not slip in the least? If so, I should like to try it. My pulleys are wide enough for 2½-inch belt, are leather faced, and are 6 in. and 9 in. diameter. The engine is a 3½-h.p. De Dion pattern.—Yours truly,

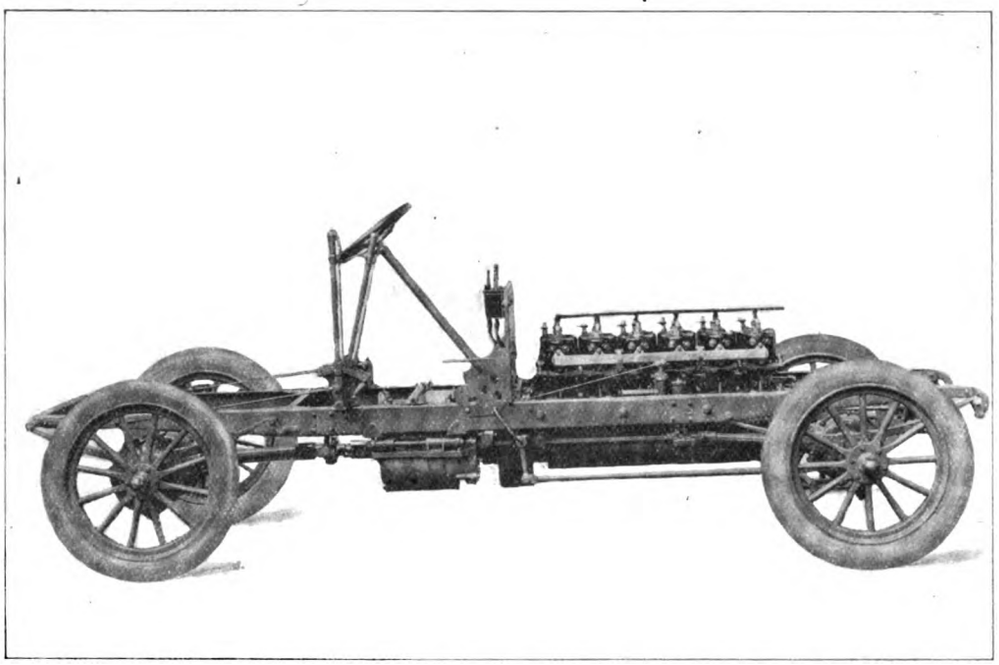
B. W. 12.

[The canvas belting referred to can be obtained from Messrs. R. and J Dick, 58, Queen Victoria Street, E.C.—Ed. *M.C.J.*]

LOSS OF POWER.

To the Editor of *The Motor-Car Journal.*

Sir,—Having seen the trouble "M.R.C.S." is in with his Oldsmobile, and having just experienced the same, I am writing to say that I think if he will adjust his high-speed clutch, giving it another eighth or even a quarter of a turn, his "loss of power" troubles, like mine, will cease.—Yours truly,



M.B.

WHEELS FOR MOTOR-CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—In reading the *Journal* of the 27th ult., I note that in a well-written article on "Wheels for Motor-Cars" the statement is made that "the experiments of Morin, however much confidence they may deserve, were made exclusively with steel-tyred carrier wheels." May I be allowed to point out that this is not so, as General Morin carried out detailed and exhaustive experiments with an Aveling and Porter road locomotive and traction wagons. From these experiments he calculated that 40 per cent. of the total power expended was taken up in overcoming the resistance of traction.—Yours truly,

Thos. C. Aveling.

Chassis of the Elsworth Automobile Company's Spyker 60-h.p. Six-Cylinder Car. (*See issue February 27*).

DRIVERS.

To the Editor of *The Motor-Car Journal.*

Sir,—Please allow me to add my quota to the discussion on the subject of drivers. I, like many readers of your *Journal*, am a little interested. The letters which you have published are of value, and such letters as that by "A. K. 33" should be appreciated by drivers as well as by owners of motor-cars. "Sub Judice" says he can polish and clean a car as well as the coachman can. That may be true, and in a former issue the Editor hinted broadly that many motor-car drivers would have to look to their laurels in this respect. My experience has taught me that a coachman of a mechanical turn of mind is to be chosen in preference to experts, driver-mechanics, etc., with their slip-shod methods. The fact is very much in evidence that there are too many boys who have gained experience in a few lessons coming out as full-blown mechanics. They can get work, and at a ridiculous wage, while men of talent and practice have to trudge the streets half in despair, day by day, and cannot find work. I do not understand Mr. Edge's letter when he writes about good men. I, like many

Digitized by Google

more men with good testimonials, cannot get work. From a good business address, however, boys can and do.

I am now filling a situation with a well-known gentleman who has had five boys, all mechanics of a few weeks' standing. This owner has two cars, a Panhard and a Mors. Both vehicles were utterly useless to him; neither would move when I took them over. I have been just one week with him. I have succeeded in getting the Mors in order; the Panhard I am tackling, and hope to have same running in a few days. The owner was getting disgusted with motor-cars, and intended selling them and have done with it altogether; but, fortunately, I finally persuaded him to let me try and put his cars in order. I never saw two cars in such a disgraceful state; yet this gentleman pays good wages. Can one wonder why some gentlemen give up motoring?—Yours truly,

A. 1304-5.

To the Editor of *The Motor-Car Journal*.

Sir,—In regard to the question of drivers, I may say I have been out now eight weeks and cannot find a suitable berth at anything near the wages I am asking, £2 and extras. I have got an excellent reference from my last master, but no luck. I agree with "Mr. Edge's" letter when he says there are few good drivers. No wonder. I know of one case where an agent offered a temporary job to a mechanic to drive a car to the country and teach the gentleman to drive, and was to have 25s. per week for his services, and when he replied that he could earn more by cleaning windows, he was told he would be scratched off the register.—Yours truly,

A Victim.

To the Editor of *The Motor-Car Journal*.

Sir,—I have read with interest the correspondence *re* drivers, and should like to give my views as a motor engineer. I have been trying for a good many months past to get a respectable situation as driver-mechanic to a private gentleman at a reasonable wage. I have had a large and varied experience. Eight years ago I was apprenticed to engineering, the last four years I have given to motor work. I have advertised, people write me offering 25s. to 30s. per week. It is my belief you cannot get a driver-mechanic who is conscientious and capable to drive and manage car in first-class order at this wage, it is only the gardening valet-chauffeurs that get situations at 25s. per week. This latter are the class of drivers whom owners are disgusted with; if they would only engage men who have had engineers' training, I am confident they would be satisfied. It is the ex-clerk, valet, or coachman-chauffeur that is lazy and too big for his boots, and not the genuine mechanic. As regards drivers taking out their friends in their employer's car, my sentiments are uttered by "Chameleon." This undoubtedly gross impertinence ought to be stopped before it has begun. I might mention I am still looking for a situation and advertising.—Yours truly,

A Won.

To the Editor of *The Motor-Car Journal*.

Sir,—I think it is wrong for the mechanics who write to your *Journal* to class all the certified drivers under one head. There are some men who have been at a motor garage for four or six weeks and are certified for driving and running repairs, and are quite capable of doing them. If all owners of cars were to employ only men who had been employed as mechanics for five or six years, there would never be enough to go round. I think that some of the certified men should be tried before the owners of cars decide to engage one.—Yours truly,

One of the Certified Ones

To the Editor of *The Motor-Car Journal*.

Sir,—I am not surprised to see the correspondence evoked *re* drivers, for I was somewhat astonished to see your remarks as to the inability to obtain good drivers, being under the impression that too many existed already to obtain situations. Recently this opinion has been modified. As an engineer, with a long apprenticeship, and as long again in the workshop with a varied motor experience, I thought possibly I might be eligible as a driver, and, like many others, replied to advertisements for same, as well as two as mechanic in the workshop. From these latter two I received most courteous replies, but from owners of cars not a single answer did I get, although forwarding a stamped addressed envelope. This clearly showed me the applicants were too numerous to answer, and this I found to be correct, for a friend of mine was selected from eighty-six applicants as driver for a Lanchester car. The owner selects one, and is disappointed. Who is to blame? Your correspondents seem to think the owner is. I am not speaking of the owner who requires a practical engineer and electrician to drive, keep in repair, do gardening and housework at £1 per week, but of the reasonable owner. I do not think he is so much to blame. But the fault lies with the "certificate granters," and there are a few who are making a nice little harvest from it, for, with a few lessons, "army and navy pensioners, stablemen," etc., can become "thorough motor mechanics." One informed me only last week he had got into trouble through granting certificates, and he would not do so again under five guineas. I do not blame him, for, even at this, a man is made a poor mechanic at 10s. 6d. a lesson, and I can only repeat what "E. E. M." said recently:—"Ask any foreman of works how long it takes to make a mechanic, and he will say, some years." No, the owner is not to blame, he does not know; thinks the certificate is definite, and learns by experience. But were he to select a mechanic from the shop, even if he sent him for a week to the works of the particular car he has to look after, he would be well repaid, and have little cause for complaint.—Yours truly,

C. E. M.

To the Editor of *The Motor-Car Journal*.

Sir,—As a driver, I should like others to consider what is the best way to get into touch with employers. Some months ago I sought a place through a man who advertised, under a high-sounding name, that he could find employment for drivers. He offered to put me on the list on payment of a small fee. The fee was paid; the writer still awaits to hear of a situation from that source. It seems that the supply and demand in connection with drivers lends itself to something of the kind that goes on with servants, with this exception. Ordinary servants pay no fee; but the motor-driver is expected to pay whether he gets a place or not. I would suggest that drivers should avoid such concerns, unless the arrangement is made to pay a fee after a place has been secured, otherwise disappointment will generally result. I have made two good changes in three years—both through the medium of a small advertisement in your columns.—Yours truly,

A. B. C.

To the Editor of *The Motor-Car Journal*.

Sir,—I have read with interest the letters which have appeared in your *Journal* regarding the scarcity of good drivers. I myself as a motor-mechanic and driver of several years' experience have found it very difficult to obtain a respectable situation. There seem so many so-called driver-mechanics who have had one week's tuition (paid for) that there is no chance for a good man at all. They seem to me to be preferred before the experienced man because they will go for such a low wage, and in the long run they are much dearer. Should anything go out of order with the car they at once have to take it to a repair shop, which means for the owner to part, where if he had had a good man it would only be the cost of a few minutes. My experience teaches me that a driver does not want another man's work to do as well as his own, for if he is any good he can find quite sufficient to do in the motor-house and on the car.—Yours truly,

A. Walker.

To the Editor of *The Motor-Car Journal*.

Sir,—As a driver I agree that there is much to be said in favour of the views as set forth by you in the *Journal*, and by the letter of Mr. S. F. Edge. Undoubtedly the qualities required to make a good driver are well set out by the correspondent "E. E. M.," in your issue of the 20th ult. Yes, employ a mechanic, and let him not be too young, but pay him a fair mechanic's wage, and if he has even seen a little private service and has a fair amount of common sense, he is the man it pays an owner to have about him. The constant and close companionship of master and man must lead to such a happy position as is rarely seen between employers and servants in other vocations, so that, given a driver who is willing, cheerful under difficulties, and ever ready to do his master's calling, he would soon gain his master's entire confidence, if it is to be gained, and I am sure there will be less cause for complaint on our side. On the driver a lot depends, for he must learn the lessons of service, which to some are so difficult and so different from that of a mechanic, who learns to have an independent spirit, which hardly adapts him for private service; so if the driver be a good mechanic, let him prove by his always cheerful and ready attention to his duties that he can be as servant to the master, and not the reverse. I am certain of one thing, good drivers' berths are very scarce; I mean a berth where the master really wants what he advertises for, a good man. I have been trying for nearly three months to get a driver's berth, either in private service or otherwise. I have had replies and interviews, and particularise one offer, viz., 30s. per week, nothing found, to have sole control of a 16-h.p. four-cylinder car, and fill in spare time gardening and making myself generally useful. This I refused, firstly on account of the wage, but principally because I was positive that to have kept this car in the condition so that its running should be a pleasure to all, and not a vexatious trial, would have required all one good driver's time and attention, as the car was in daily use, and was to be kept clean. I do not want an extravagant wage, but in fairness to all mechanics I expect a fair price for my labour; but it is hard to get this, for there are so many who profess to thoroughly understand seven or eight different types of cars, and work for 25s. to 30s. a week. I have been cut out by price on more than one occasion, and think that if a fair wage is offered there would not be so much difficulty in getting good English drivers; it is a matter of £ s. d. I only add that it was a pity, when the Motor-car Act was being put through, that a clause was not inserted making it compulsory for drivers applying for a licence to have to pass similar examinations as a 'bus driver does before he can get his badge.—Yours truly,

No. 3966.

Loss of Power.—Messrs. Jarrott and Letts, Ltd., write:—Having noticed in your esteemed paper a letter from "M.R.C.S." regarding loss of power in the Oldsmobile, we write to say that if this gentleman will favour us with his address, we shall be pleased to give him every assistance. There is no reason why his Oldsmobile should lose power in the way he says it does."

The "Be Tall" Terminal.—In answer to several enquirers, the terminal referred to under this name in our issue of the 27th ult. is made by Messrs. A. and B. Apted, 41, Blondel Street, Battersea, S.W.

MOTOR-CAR UPKEEP.

AT a meeting of the Scottish Automobile Club (Western Section), held in the Windsor Hotel, Glasgow, Mr. John M. Ross being in the chair, Mr. John Adam, chairman of the section, and Mr. J. Hunter Steen introduced a discussion on "The Cost, Care, and Upkeep of the Motor-car." Mr. Adam stated that "cost" was such an elastic term the prospective buyer should make up his mind first as to the use to which he intends to put his car, the carrying capacity required, and having regard to the amount of money he was prepared to spend, should then fix upon the type of car he wished, and thereafter make the best terms therefor possible. In his opinion for one who was an absolute novice and who had yet to learn to drive it was advisable to purchase a second-hand car and practice on it. He dealt extensively with the question of the housing of motor-cars and submitted plans which he had had prepared exemplifying his ideas on the subject. He had confined himself to a small house for a single car, which he advised should be 18 ft. by 9 ft., that the pit should be near the door, 6 ft. by 3 ft., and that the depth should be anything up to 5 ft., if the depth of the drainage system would permit of this. His plans provided for a house of corrugated iron with wood lining, the roof having a layer of felt between the corrugated iron and the wooden sarking, that the light should be borrowed from the side, and that there should be through ventilation. He had an estimate for the cost of such a house amounting to £24. A cement floor with the necessary trap connected with the drain, with pit, would cost ten guineas and a slow combustion stove £4 10s., all extra to the £24 mentioned. Mr. Adam thought that this would be found to be a sufficient and satisfactory house for a motor-car on the most moderate basis, though he said any person proposing to spend more money on it could do so advantageously, and he emphasised the mistaken policy of paying a heavy price for a motor-car and grudging a sufficient sum in order to its being properly housed. Mr. Adam advised all prospective entrants to automobilism, immediately on getting their car, to make themselves thoroughly acquainted with its working, and said that thereby they would have much less difficulty in the event of any roadside or other troubles, and counselled a regular and methodical examination and adjustment of parts and brakes. He submitted elaborate statistics which had been prepared by Mr. Steen of his cost of running a 10-h.p. car for 7,065 miles, which summarised as follows :—

	£	s.	d.		
Light, oils, and grease	3	5	6½	·11	of 1d. per mile.
Petrol	22	12	8	·77	do.
Repairs and replacements ...	12	9	11	·42	do.
Tyres	27	15	3	·86	do.
Sundries, licence, stabling and washing	14	10	11½	·56	do.
	£80	14	4	2·72	do.

The quantity of petrol used was 346 gallons, the average consumption giving 20·41 miles per gallon. Mr. Steen explained that all the above running had been done on Scottish roads, many of which were of the roughest and most primitive type. Mr. Adam further submitted similar statistics which were handed to him in the meeting by Mr. Seligmann with regard to a 12-h.p. car, and which worked out as follows :—

Petrol	·76	per mile.
Oil	·066	,,
Grease	·033	,,
Electric Current	·016	,,
Tyres	1·332	,,
Repairs and sundries	·212	,,
Stabling, washing, and license ...	·417	,,
	2·836	

These results were based on an experience of 5,000 miles, and attention was drawn to the marked similarity between the two sets of results attained on similar makes of cars, both of which, it was mentioned, were 1903 cars. He dealt with the cost of transport of goods by motor-car and quoted the figures used by Mr. J. E. Thornycroft in his lecture to the Glasgow University Engineering Society a few days before, with regard to vehicles for goods transport, in which it was made out that a steam lorry costing £665 would cost 2·75 of 1d. per ton mile. Mr. Adam also submitted statistics which he had prepared with regard to the use of a public service vehicle, 12-h.p., costing say £500 and based on an estimated annual running of 7,800 miles, which brought out that the expenditure would be as follows :—Solid tyres, £42 ; petrol and lubricants, £32 ; motor-man's wages and entry form, £80 ; attendant, £59 ; repairs and upkeep, £30 ; interest on capital, £25 ; depreciation, £52. Total, £320.

In the discussion which followed many interesting points were raised. Mr. Smith quoted his experience on a 6-h.p. four-seated car, which worked out at almost exactly 2¾d. per mile, and gave it as his opinion that the question of depreciation was one which should be taken into account, and this he estimated in the case of an ordinary pleasure vehicle could not be less than about 2d. per mile, 17½ per cent. on the reducing values being, he thought, a fair charge, though at the same time he pointed out that this would only be applicable after a term of say two years, as the great bulk of the depreciation consisted of the difference in value between a new and second-hand car, and this was occasioned by even a few months' working. Mr. Murray pointed out that in the case of those who had stated their experiences it had to be borne in mind that they were their own drivers and looked after the cars personally, and he thought this had a very material effect on the reduction of expenses, and more particularly with respect to the cost of tyres. Mr. Steen expressed his view that the bulk of cars were too lightly tyred, and that many canopies were so heavy that the strain on the tyres tended to shortening their lives, and that tyres should never be run under eighty pounds pressure, and in reply to an inquiry, gave it as his experience that non-skid chains, while they slowed the car about three miles per hour in ordinary running, increased the speed considerably on greasy roads and aided considerably in lengthening the lives of tyres. His experience was that the chains would run about 700 miles, after which the expense of renewal amounted to about 20s. per wheel. It was pointed out that all the costs quoted apply to pneumatic tyred vehicles, and that in no case was the owner's insurance premium included in the figures submitted.

CASES DISMISSED.

AT Woking, on Saturday, Claude Browne, of Onslow Gardens, Kensington, was summoned for driving a motor-car to the common danger at Ripley. Mr. Staplee Firth defended. Sergeant Jarrett alleged that the defendant had covered a measured distance at thirty miles an hour. Mr. H. J. Swindley gave evidence against the police stop-watches. Tests had proved, he said, that the 30s. stop-watch which Sergeant Jarrett used could be unconsciously stopped and started again, so that it would show a car as covering five miles in as many seconds. On the Thames Embankment motor-cars travelled up to 17½ miles an hour, and this at a spot passed by 800 vehicles in sixty minutes. The magistrates found there was a doubt as to the speed at which the defendant was going, and dismissed the case.

AT the Derby Borough Police Court, on Tuesday, Mr. A. J. Eggleston, of Osmaston Road, Derby, was summoned for driving a motor-car at a reckless speed at Derby, on February 23rd. Police-constable Evans having given evidence and the defence having been heard, the Chief Constable said he brought the case forward so that motorists should understand that speed had nothing to do with dangerous driving and as a warning to others. The Bench, after consultation, dismissed the case.

MR. WILLIAM FORSTER, of Colherne-road, Kensington, was summoned, before Mr. Lane, K.C., at the West London Police Court for driving a motor-car at a speed exceeding 20 miles an hour. Police-constable 37 F. R. deposed that on Sunday afternoon, Feb. 14th, he timed the defendant's car with a stop watch over a measured distance of 220 yards along the Kensington-road, and calculated that he covered it in 16sec., or an average of 28 miles an hour. Another officer confirmed his estimate, and Police-constable 41 F R., who gave the signal, stated that he stood 12 yards east of the starting-point and waved his handkerchief as the car passed him. The defendant denied the charge, and called witnesses to prove that the road was full of traffic, and that there was a brougham in front of his car over the whole distance. Mr. Lane, K.C., said he was not satisfied that the estimate of the stop watch was correct, and, indeed, it was very liable to infirmity in the hands of persons who had not been trained to its use from their youth. He dismissed the summons.

A FINE AND A DISMISSAL.

AT Beaconsfield Sessions, at the instance of Major-General Upton Prior, of Gerrard's Cross, Buckinghamshire, Mr. Dudley Truman was summoned for driving a motor-car at a reckless speed at Chalfont St. Peters, also for failing to sound a horn or bell giving warning of his approach. The complainant was out for a walk with his three dogs, and in a narrow portion of the road he put his hands up for the defendant to stop, fearing that the animals would be run over. Mr. Truman did not obey the signal, with the result that one dog was sent by the car flying head over heels. For the defence, the allegation of recklessness was denied, and it was stated that the dog backed into the car, and that a horn was sounded. The bench fined the defendant £2 and 10s. 6d. costs for reckless driving, the other part of the charge being dismissed.

ENGLISH v. ROMAN.

AT Hailsham Petty Sessions, Inverness Watts, of Heathfield, was summoned for not having a proper number on a motor-car. Mr. Lawson Lewis prosecuted, and stated that defendant's identification plate on his motor-car bore the letters A.P. ccxxxiii., instead of the regulation number 233. On this being reported to the Chief Constable, Major Lang, he wrote to the defendant pointing this out. Mr. Lewis contended that by the provision of the Act the lettering and numbering of the plates should conform with the model issued by the authorities, and should be in English capital letters and ordinary English numbers. Police-constable Snelling testified to seeing the car with the plate in question attached, which he "could not understand." Robert Jenner, clerk from the office of the Justices of the Peace at Lewes, stated that a copy of the model plate was issued to each applicant for a motor-car license. Defendant denied that he failed to reply to the Chief Constable's letter, and urged that it was nowhere stated that Arabic numbers had to be used. Roman numerals were employed in all Acts of Parliament and on coins. The Bench were unanimously of opinion that defendant had evaded the law, which had been clearly explained to him, and imposed a fine of £1 and costs—£1 9s. 6d. in all.

CLUBS AND ASSOCIATIONS.

NOTTINGHAMSHIRE.

AT the annual meeting of the Nottingham and District Automobile Club, held at the Black Boy Hotel, Nottingham, it was decided that in future the Club should be known as the Nottinghamshire Automobile Club. The opening run will take place to-day (Saturday), to Meldon, members meeting at the Red Lion, Nether Broughton, at 2.30 p.m.

NORFOLK.

AT the annual meeting of the Norfolk Automobile and Launch Club, Lord Claud Hamilton was re-elected president, Mr. Edward Reeve hon. solicitor, Mr. F. W. Burton-Fanning hon. treasurer, Mr. J. E. Warne Hewlitt hon. sec. of the motor-car section, and Mr. H. L. Clark hon. sec. of the motor-launch section. It was agreed to continue the club room at the Royal Hotel, Norwich, and also to hold the opening meet of the Club on Easter Saturday.

HERTFORDSHIRE.

THE opening run of the Hertfordshire Automobile Club has been postponed to Saturday, the 26th inst., the route followed being from St. Albans to Hatfield, Hertford, and Stevenage. The start will be from St. Peter's Street at 2.30 p.m.

As a result of the Club's action in the matter of the application of the Corporation of St. Albans for power to impose the ten-mile speed limit on the City roads, several influential tradesmen and residents, in addition to most of the local motorists, have forwarded objections to the Local Government Board and the Town Clerk. The local feeling is that such a limit is totally unnecessary, the Act providing amply for the safety of the public, and that any purely local restrictions such as those sought for would have the effect of causing motorists to avoid the city as much as possible, and lead to a great deal of money, which now finds its way into St. Albans, being spent elsewhere.

MANCHESTER.

THE members of the Manchester Automobile Club have just had their fourth annual dinner at the Albion Hotel. Mr. Frederic Smith presided. In proposing the toast of "Automobilism" the Chairman drew a contrast between the year 1900 and the present time. He remembered riding on a car in the former year which was running something like a small traction engine, and he happened in his innocence to remark that they were going very well. "Don't say anything," whispered his companion, the driver, "or we shall have a breakdown." How different it was now. The modern motor-car had become a wonder of mechanical design and construction, and as beautiful in its simplicity of control. Smooth, silent, reliable, it was as different from its prototype as the modern locomotive was from the "Puffing Billy." He believed there was a great future before automobilism; it would be a source of pleasure and health and convenience to mankind. When they got a perfect pneumatic tyre, an approximately perfect road, and a careful user of the road, there would be no limits to its importance as a friend of humanity. Mr. D. Q. Henriques responded, and gave an amusing account of his motoring experiences. The toast of the visitors was proposed by Mr. Arrowsmith and responded to by Mr. Lennox Lee, and also by Mr. G. Haworth. A vote of thanks to the Chairman, proposed by Mr. J. A. Morris, terminated the proceedings.

GLOUCESTERSHIRE.

THE first annual meeting of the Gloucestershire Automobile Club was held under the presidency of Dr. H. P. Fernald. There were also present Dr. Halliwell, Messrs. A. H. Wyatt (treasurer), H. Dyer (hon. sec.), F. J. Bennett, F. M. Bostock, A. Arthur Dale, E. A. Stretton, C. Bullock, A. Meats, F. Sims, G. F. Ticehurst, S. H Wellington (Gloucester), A. G. Sanders, J. Wheway, and H. E. Ranken, of Beckford Towers. The minutes of the last meeting having been read by the hon. sec., the hon. treasurer produced the balance-sheet, showing a balance in hand of £26 16s. 9d. The chief item of revenue was thirty-four members' subscriptions of a guinea each. The balance-sheet and annual report were both adopted. The hon. treasurer read a number of proposed alterations in the club's rules, the chief of which was the change of its name from the "Cheltenham and Gloucestershire Automobile Club" to the "Gloucestershire Automobile Club." On the proposition of the president, seconded by Mr. Meats, the alterations were adopted en bloc.

After a vote of thanks to Mr. Wyatt for drawing up the report, the president remarked that his year of office having concluded, he was bidding good-bye to the position he had held with so much pleasure, one reason being that he was leaving the town to practise in London. He should not be surprised to hear that next year they had brought the membership up to 150 or 200. Gloucestershire ought to furnish 300 or 400 members. Mr. F. J. Bennett took the chair *pro tem.*, and proposed a vote of thanks to the retiring chairman and the hon. sec., who had also signified his intention of vacating his office. He remarked that Dr. Fernald had been their moving spirit. He was sure it was a sorrow to all of them that Dr. Fernald was removing from Cheltenham, and particularly that he was severing his active connection with their club. However, it would be gratifying to them all to know that he would continue his membership. Mr. Bennett also commented upon the excellent services rendered the club by their hon. sec. Mr. Dale seconded and referred to the many ways in which the kindness and generosity of Dr. Fernald had been manifested. The motion was adopted with much cordiality. Dr. Fernald, the hon. secretary and the hon. treasurer also returned thanks. Mr. Bennett remarked that it would be a satisfaction to them to know that they had a worthy successor to Dr. Fernald, and when he told them that that gentleman was Mr. A. H. Wyatt, he thought a unanimous election was assured. He mentioned Mr. Wyatt had served them admirably in the position of treasurer, and well deserved the promotion which he (the speaker) would formally propose. Mr. Dale seconded with much pleasure, and the motion was agreed to amidst applause. Mr. Wyatt took the chair and acknowledged the compliment paid him. Mr. F. M. Bostock was elected hon. treasurer, and Mr. A. Arthur Dale hon. sec., and the following were balloted as a committee, with the officers as *ex officio* members:—Dr. Halliwell, Messrs. F. J. Bennett, A. Meats, E. A. Stretton, S. H. Wellington, A. G. Sanders, H. E. Ranken, E. Sims, G. F. Ticehurst, H. Dyer, and W. R. Hughes. Dr. Fernald and Mr. A. Arthur Dale were appointed as representatives of the club to attend the Motor Union meetings in London.

EXHIBITION AT MANCHESTER.

THE Manchester and District Cycle Trades Association, Limited, is to be congratulated on the excellent show of motor-cars, motor-cycles and accessories now being held at St. James's Hall, and which was opened on Monday by the Earl of Shrewsbury. Altogether there are close upon a hundred exhibitors, the vehicles displayed comprising all the leading types. Messrs. J. Walmsley and Company attract attention with the Crossley *chassis* as well as with De Dietrich, Gladiator, and Oldsmobile cars, Darracqs and De Dions are shown by Mr. T. Garner, Panhard and Talbots by Messrs. Joseph Cockshoot and Company, 6, 8, 12-h.p. Brown cars by Messrs. Brown Bros., the Cotterean cars by Messrs. McNeill, Hutchison and Borthwick, Wolseleys and Lanchesters by the Bolton Motor Company, Limited, Vinot, Panhard, Lancaster, and Enfield cars by Messrs. Newton and Company, Humberettes by Messrs. Humber, Limited, Peugeots, Stars, Argylls, and White steam cars by Messrs. Bennett and Carlisle, Rothwell cars by the Eclipse Machine Company, and Lanchesters by Mr. R. Ramsbottom. The Belsize Motor-Car and Engineering Company, Limited, show their new three-cylinder car, and the "Belsize Junior;" Messrs. Horsfall and Bickham display the new models of Horbick cars, including the "Horbi k Minor," illustrated in a recent issue; Messrs. R. and W. Brownswood exhibit the Sunbeam car, the Protector Lamp and Lighting Company a neat little two-seated car, and the Eagle Engineering and Motor Company the Eagle light car and runabout. There is also a large display of motor-cycles and motor-car accessories.

MESSRS. DAVID CARLAW AND SONS have a garage for fifty cars at 11, Finnieston Street, Glasgow.

THE Maudslay Motor Company, Limited, have established a London showroom at Albert Gate Mansions, Knightsbridge, W.

"NOTES ON AUTOMOBILES" was the title of a paper read at a meeting of the Rugby Engineering Society last week by Mr. B. Hopps.

FROM the Gobron Motor Company comes a copy of a new catalogue of Gobron-Brillie cars, which are made in 12-h.p., 18-h.p., and 25-h.p. sizes, and with various types of bodies.

A COMPANY has been formed at Munchwilen (Thurgau) Switzerland, to establish public services of motor-cars between Fischingen and Munchwilen and between Turbenthal and Munchwilen.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to THE EDITORIAL DEPARTMENT, MOTOR-CAR JOURNAL, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

The Editors do not hold themselves responsible for the opinions expressed by their correspondents, or for statements and facts which do not appear in the editorial columns.

The Editors and Publishers beg also to state that they will accept no responsibility for unsolicited contributions, even if used, unless payment for same is directly specified in forwarding, and the terms arranged before publication.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, MARCH 19, 1904. [No. 263.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

The British Eliminating Test.

THE Bill to enable the eliminatory trials for the Gordon Bennett motor-car races to be held in the Isle of Man passed through both branches of the Manx Legislature on Tuesday. In the Bill as sent down by the Council the House of Keys introduced a clause confining the races to any three days not including Sunday. Another amendment making it imperative on the A.C.G.B.I. to bear the expenses entailed on the Highway Board was withdrawn, it being left optional with the Board to charge expenses. The course selected is one of fifty miles, the roads being of fair width and excellent surface. The starting point is west of Douglas, then by way of Laxey, Ramsey, Sulby, Ballaugh, St. John's, and Fox Dale to Ballasalla, and thence back to Douglas. There is much rejoicing among Manx people that their island has been selected for the trial, and the Legislature is to be congratulated upon the expedition with which the matter has been carried through.

◆ ◆ ◆

Local Government Regulations.

ON another page we make reference to the regulations of the Local Government Board, issued during the present week, and which will be found to confirm the forecast we published in the *Journal* of January 2nd last. These seem to have been drawn up with due regard to common sense, and, altogether, motorists have no need to complain of the attitude the Board has adopted since the Act was passed. The use of search lights on motor-cars is prohibited, and the hope expressed that motorists will themselves consider the question of the very dazzling lamps which some employ, so that there need be no need for further regulations on this point. Copies of the order and circular are now on sale from Messrs. Eyre and Spottiswoode, and there will doubtless be many questions arise, with which motorists would do well to make themselves acquainted. During the last few days we have received several enquiries with regard to the points raised in the elucidation of the Act, and to these we propose to refer in our next issue.

◆ ◆ ◆

Roads in Ireland.

IT is gratifying to hear that certain local authorities in Ireland, recognising the educational influence exerted by the motor-car tour of last year, are beginning to set their roads in order in view of the touring season, which, should the weather ever settle down to old ideas of self-respect, will commence ere long. A local gentleman in co. Clare has just secured a writ of mandamus in the superior courts of Dublin, insisting on the Clare County Council putting a certain public road into good condition and repair. Elsewhere also we hear of public-spirited men taking steps to secure the local authorities doing their duty in this respect. While on this subject, we would emphasize, as we did just after the Gordon Bennett Race of last year, the necessity of the authorities in the South of Ireland supplying the signposts which have, hitherto, been so conspicuously absent where they were most required. This was forcibly pressed upon us when, making for Cork, we found ourselves stranded at Dungarvan, owing to the absence of signposts on the road from Arklow, and instinct having, on that occasion, led us to a wrong conclusion.

◆ ◆ ◆

Horse v. Motor.

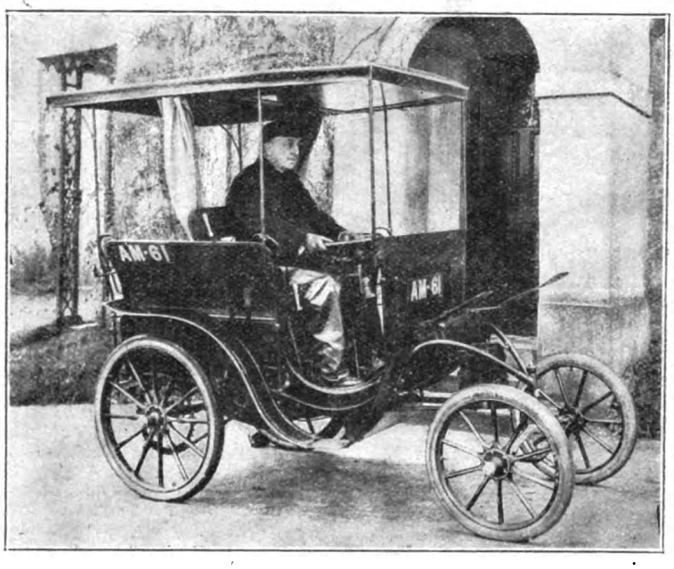
FOLLOWING upon the confession of Sir Oswald Mosley as to the future of horse-breeding in this country comes a declaration by Sir Walter Gilbey, who, at a meeting of the Hunters' Improvement Society, complained that horse-breeding was not a flourishing industry in this country, and said that it was very disheartening to see the figures relating to the importation of foreign horses into England. He believed the motor-car had come to stay, but there was nothing like rivalry, and he considered that more horses would be seen in Hyde Park during the next ten years than had ever been seen before. For one reason, ladies did not look nearly so pretty in a motor-car as mounted upon a fine horse. We have always recognised the popularity of the horse for the Park. What we contend is that by the adoption of the motor-car he will be spared many of the burdens and hardships now imposed on "the friend of man."

◆ ◆ ◆

Stop Watches no Evidence.

SOLICITORS throughout the country are expecting the new Motor Car Act to become almost as valuable as the horse so far as their professional engagements are concerned. Certainly, from the reports of cases heard recently, there seems a reasonable hope of successful defences, and one result has been the employment of counsel far more freely than last year, when a summons was invariably followed by conviction. In a case heard at Steyning on Monday, Mr. Humphrys showed considerable discretion in the way he handled the police evidence with regard to stop watches, and by quoting other cases in Surrey and the method adopted in East Sussex was able to shake the faith of the magistrates in the police stop watches. From that point to a dismissal of the case was an easy step.

◆ ◆ ◆



Another Motor List.

WHEN the new legislation came into operation we refrained from publishing the cases where motorists were fined, as such convictions, publicly recorded, served as useful police information. Many of the summonses were the result of mere carelessness, so that it seemed unjust to give the police the opportunity of branding motorists as to first, second, and third convictions. But from letters received from motorists there is evidently much interest felt in the prosecutions throughout the country, and as it is clear the publication of these will be of service to motorists in warning them as to the places where the police are active, we propose in our next issue to give a weekly list, without names, of the offences with which motorists are charged.

A Clerical Motorist.

A WELL-KNOWN clerical motorist is the Rev. W. C. K. Sylvester, Vicar of Chitterne-All-Saints cum Chitterne-St. Mary, on Salisbury Plain, near Codford, Wilts. He is the youngest son of the late Dr. George Mayris Sylvester, of Trowbridge, Wilts, and a descendant of the old family of the Sylvesters, who have resided in Wiltshire for the past 200 years, but who originally came from Burford, in Oxfordshire, where, in the parish church, there is an aisle called "The Sylvester Aisle," the same being full of monuments erected to their memory, and dating back for over 300 years. At the time of the great rebellion (Charles I.), the then head of the family advanced a considerable sum of money in support of the Royal cause; but, needless to say, like most others, never saw it again. Mr. Sylvester has been accustomed to a mechanical means of locomotion from his earliest childhood, naturally beginning with the humble perambulator, and then aspiring to a velocipede; a curious kind of machine, which consisted of a sort of box arrangement, as a seat, fixed between two large wheels on a triangular-shaped frame; a small wheel being at the apex to

guide with, the same being moved by a long straight handle resembling that of a bath-chair. The movement of the whole was imparted by a pair of long treadles acting directly upon the axle. Then, after some years, an advance was made to a tricycle, and that in turn superseded by a freewheel back-pedalling brake bicycle (after a process of evolution from the fixed wheel), and last, but not least, a motor-car. The one he now drives is a 5-h.p. Stirling light dogcart. Being four miles from a station and eight from the nearest town, Mr. Sylvester finds it far less expensive and more convenient in the long run to keep a car than to possess a horse and carriage.

◆ ◆ ◆

The Aero Club Display.

AMONG the exhibits in the North Gallery Annexe, at the Agricultural Hall next week, will be found the original Beedle airship and a model, an important display by Messrs. Spencer Brothers of balloon apparatus, including a model of Stanley Spencer's airship, and the Rev. J. N. Bacon's collection of photographs. Dr. Barton will show a propeller, and propellers will also be exhibited by Mr. W. A. South and Mr. W. Cochrane, whose model dynamic flying machine will be on view. Aeroplanes and kites have been promised, and there will be a quite unique collection of pictures, photographs, and curiosities, lent by Sir David Salomons, the Hon. C. S. Rolls, Mr. Griffith Ewer, and other well-known aeronauts. This interesting section of the Exhibition has been organised by the Aero Club.

1905.

LONG ere one exhibition is closed the most enterprising firms are considering the next. The chief places at this year's show were booked a twelvemonth since, and by the time these lines appear in print settlements with regard to the positions of representative firms at the 1905 display will be made. This is a matter which few people delay, there being always a familiarity of position associated with stands at an Exhibition that is regarded as a useful asset by those acquainted with the practical value of such trade displays.

◆ ◆ ◆

Motor-'Buses v. Tram Cars.

AT a meeting of the Eastern Section of the Scottish Automobile Club, held at Edinburgh, Mr. John Stirling has been speaking on this subject—one with which he is fully acquainted from the practical side. Dealing with the older invention, he said there was no doubt that the early tramways served a useful purpose. The idea that tramways were a modern necessity took hold of many minds, but he ventured to make contradiction of this idea and to say that tramways were now no longer a modern necessity. so far, at any rate, as their cities and large towns were concerned, nor were they now the most satisfactory or economical method of moving the population of great centres from place to place. Tramways, with their huge cars, constituted a perpetual street obstruction. They ran on their fixed lines, and all other traffic must make way for them. Alongside the remarkable growth and development of electrical engineering, and especially that department of it relating to locomotion, there had been arising and advancing steadily a new competitor which promised to become, at no great distance, a serious rival to the tramways. This was the evolution and perfecting of the motor-omnibus. A discussion followed, in which Sir J. H. A. Macdonald, K.C.B., took part. He fully endorsed and amplified the views expressed by the lecturer. Mr. Eunson, from Dunedin, New Zealand, who is at present in this country to study the question of motor-car traction in place of expensive tramway systems, addressed the meeting, and said that he and many other tramway directors were fully alive to the likelihood of motor-cars proving their superiority over the present tramway system. Amongst other speakers were Mr. John Wilson, Mr. Norman D. Macdonald, Mr. Alexander M'Kenzie, Councillor Macfarlane, and the chairman, Mr. John Macdonald.

◆ ◆ ◆

Lamps.

A SUGGESTION has been made for a competition of head lights, side lights, etc., used on motor-cars, and the A.C.G.B.I., it is suggested, might well organise a test to help motorists to determine the best kind of lamp suitable for their purpose. This is well worth the consideration of the manufacturing firms, as well as of agents, and, in view of the attempt to secure new regulations from the Local Government Board on the subject, the idea is one to be welcomed. There are many good types of lamps on the market, but motorists must often be in a quandary as to the pattern best suited for their requirements. The details of such a competition would require careful consideration. In fact, before committing themselves with regard to the practicability of the proposal, the trade will probably want to know something more of the details than is at present available.

◆ ◆ ◆

Railway Excursions.

FROM information received from all parts of the country, we are satisfied that the attendance of provincial visitors at the Exhibition will be large and representative. The Great Western Railway Company will be running excursions to Paddington from Birmingham and Wolverhampton and district on the 19th, 21st, and 23rd. On the Saturday and Wednesday there will also be cheap bookings from all the towns in the

Digitized by Google

Thames Valley. On Monday three and four-day trips will be run from the West of England. The Midland, Great Northern, L. and N.W.R., Great Eastern, and other lines will also provide facilities for cheap excursions, so that everything has been done to secure the interest of those who are likely to develope into motorists, as well as of those already owning cars.

◆ ◆ ◆

Motor 'Buses at Eastbourne.

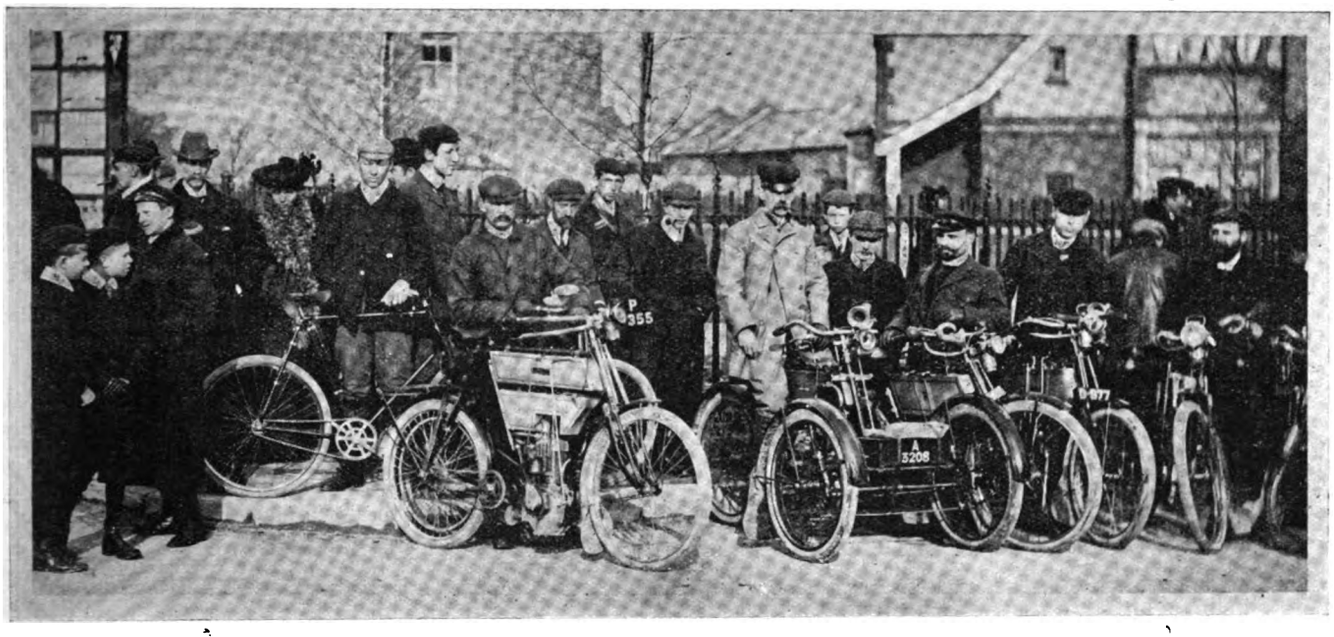
At the last meeting of the Eastbourne Town Council, an interesting report on the working of the motor-'bus service was brought forward. Although a profit of only £67 has been made on the venture from its inauguration to the end of last year, there is no doubt in the minds of local people that its success is entirely sure. At the rate of progress disclosed by the accounts, the Town Council should be in a position to repay the whole capital expenditure in seven years, whereas the Local Government Board have granted ten years for the loan. 294,922 passengers were carried, the total receipts therefrom being £2,069. Among the items included in the expenditure were, wages £367, general repairs £84, tyre repairs £8, repairs to machinery £205, petrol oil, waste and cleaning materials, £365, tyres worn out and depreciation on tyres still running, £626. The latter item, it will be seen, was greater than that under any other heading, but it should be minimised in the future. When that is done a good profit should result to the Corporation from their enterprise. 36,800 miles were run at a total cost of 1s. 1·6d. per car mile, the cost of tyres was 4.09d. per car mile, the cost per week of each car being £17 9s. These figures should give confidence to other local authorities intending to embark upon similar ventures, and also to assure the public that there is a financial future before the motor-omnibus.

◆ ◆ ◆

One good Turn Deserves Another.

Having regard to the usefulness of the motor-car to the police, as illustrated in the police courts last week, we are glad to see that the authorities in the Metropolitan area are proving friendly to motorists. An advertisement in the daily papers this week reads:—"Metropolitan police.—Found, in the South-Eastern district, during last month, a pair of motor-lamps.—Apply, East Dulwich Police Station, S.E." But then this is in London, and not near Ripley. One can hardly imagine Sergeant Jarrett—who lost another case at Woking the other day—going out of his way to assist some careless motorist.

◆ ◆ ◆



Our Directory of Numbers.

Provincial motorists whose numbers have not yet appeared in our Directory are invited to call at the office in the Exhibition and leave their names, addresses, and numbers for publication in future lists. Considerable interest has been taken in the lists already published, hence the suggestion that further numbers should come to hand during the period of the Exhibition, when the attendance of motorists is likely to be unprecedented.

◆ ◆ ◆

Motor-car Imports and Exports.

No less than 538 foreign motor-cars were imported into this country during last month, their value being returned at £185,499. "Parts" were responsible for £21,496, bringing up the total imports for February to £206,995, as against only £120,772 in the preceding month, and £94,735 in February, 1903. So far this year, that is to say for the first two months, the imports stand at £327,767 or roundly £60,000 more than in the same period of last year. We are glad, however, to be able to record an upward move in the exports of British automobile productions. Thus last month sixty-five vehicles were shipped, these with the "parts" being valued at £28,195. For the two months ending with February the exports are returned at £56,831, or £13,000 more than in the corresponding two months of 1903.

The Opening Run of the Motor Cycling Club. The Gathering at Purley Corner.

◆ ◆ ◆

The Stupidity of Pedestrians.

We are glad the President of the Manchester Automobile Club has been emphasizing the stupidity of the average pedestrian with regard to ordinary street traffic. The danger of the motor-car is comparatively small in comparison with the danger, both to themselves and to others, caused by that vacuous stupidity which too often marks the ordinary man in crossing a busy thoroughfare. Two-thirds of the accidents that occur in the streets of large towns are the direct result of carelessness on the part of the individuals concerned. How they are to be obviated it is difficult to say. The use of recognised crossing places might do something to minimise the evil, but that it would effectively stop it is too much to hope for in view of the carelessness of the average human being.

"Quiet to Ride and Drive."

A CURIOUS case was heard at the Lambeth County Court the other day in which there figured as the central feature a horse, warranted "quiet to ride and drive." This would not, however, face motor-cars, and the purchaser, who brought an action for breach of warranty, admitted that, whilst it was all that could be desired in every other point, its objection to the modern automobile, when seen on the road, was such as to destroy the value of any warranty as to its quietness among traffic. Judge Emden, whose practical experience as a motorist has frequently stood him in good stead when hearing actions in connection with road traffic, held, in view of the large number of motor-cars now in use, that the term "quiet to ride and drive" must receive a broader construction than it had done in the past. This should be borne in mind by all who deal in horses, and the fact that the Bench is beginning to recognise motor-cars as ordinary features of traffic must be regarded as a triumph for the mechanical vehicle.

◆ ◆ ◆

Lights on Vehicles.

THE Committee of the Motor Union of Great Britain and Ireland, the annual meeting of which will be held at the Agricultural Hall, London, on Tuesday next, has adopted Mr. Rees Jeffrey's suggestion concerning the steps that might be taken to better the existing law and practice as regards the lighting of vehicles. The recommendations are as follows:—1. A general and systematic attempt to strengthen the local bye-laws. This might be done by one or more of the following methods: Arranging a deputation to the Home Office and inviting that department to bring pressure to bear on the local authorities to adopt bye-laws in districts which are at present without them, and to improve them in those districts in which existing bye-laws are only partial in their operation. Circularising the local authorities. Moving the local clubs to organise deputations to meet the responsible committees of the local authorities. Inviting the co-operation of the County Councils Association and the Association of Municipal Corporations. 2. Including a Universal Lights Bill in the political programme of the Motor Union, and taking the following steps to press the measure on the attention of Parliament. Introducing a Bill into Parliament, either alone or in concert with the C.T.C. and the N.C.U. Asking the President of the Local Government Board to receive a deputation in support of such a measure. Suggesting to members of the Union that they should invite their Parliamentary representatives to vote in favour of a Universal Lights Bill.

◆ ◆ ◆

Care Required.

THERE is trouble among the Brighton motorists, who have been threatened with having the Front closed for traffic on Sunday mornings, owing to the reckless, or alleged reckless, driving of motorists who are not resident, during the last few Sundays. The matter has been before the Brighton Town Council, to which body the inspector of police has complained that no heed is taken of the regulations by motorists. Not only had he been unable to overtake cars rushing along the front on his bicycle, but a mounted trooper called into requisition in a friendly way had also failed to accomplish the task. Several Councillors have expressed themselves in strong terms against the conduct of motorists who are thus bringing the movement into disrepute, and we would ask for reasonableness on the part of those who drive, especially when visiting towns in which they are non-resident.

◆ ◆ ◆

Continental Touring.

LAST week, at the Automobile Club, Mr. Roger H. Fuller read a paper on Continental Touring, in which he gave some useful information with regard to routes to Paris, some of which will appear in the guide-book shortly to be issued by the Club. Touring in France does not differ very much in cost from what it is in the British Isles, and the roads, generally speaking, are excellent, with the exception of those in towns and villages. In Spain, however, they are quite unfit for modern racing cars, and even with touring cars require much patient driving. Mr. J. Pennell was in the chair, and gave some of his own interesting experiences as a motor-cyclist on the Continent. Lieut. Windham opened the discussion, and emphasized a point Mr. Fuller had mentioned with regard to free garage accommodation at Continental hotels, an innovation which hotel keepers in this country might make with considerable advantage both to themselves and to motorists. The discussion took a general turn, and Mr. Schlentheim, making reference to the question of routes to Homburg for the Gordon Bennett Race, advised motorists to go through Holland. He had gone that way to Germany, and had found the road was fine and wide. There were no duties on the German frontier, and the distance was about 300 miles. A hearty vote of thanks was accorded to both lecturer and chairman at the conclusion of the meeting.

◆ ◆ ◆

Exhibition Events.

SEVERAL interesting social events will take place at the Agricultural Hall next week. On Tuesday the annual meeting of the Motor Union will be held; Wednesday will be the Club day (when the charge for admission will be raised to half-a-crown), and the annual meeting of the Automobile Mutual Protection Association will also be held on that day. On Thursday a reception will be held by the Ladies' Automobile Club, and on Friday the Auto-Cycle Club will have a meeting. These events will prove of considerable interest to exhibitors, who may confidently look forward to a very busy time.

◆ ◆ ◆

Kentish Enthusiasm.

TECHNICAL education in motor-car work is being developed with almost surprising rapidity throughout the country. Many times have we recently referred to developments in this direction in London, and we are glad to learn of the success of the classes established at Tunbridge Wells, at which the Mayor was one of the first students. In fact, at that place it has been found necessary to open a second class, so great has been the number of applications for membership, and it is evident that, given a supply of information on automobile topics, the demand will grow.

THE King and Queen went to Esher on Wednesday, His Majesty using for the first time in public his new Mercedes motor car.

THE Committee of the Corporation of the City of London has asked the Local Government Board to approve of a speed limit of eight miles an hour for motor-cars when passing through the City of London.

HAVING memorialised the Local Government Board to restrict the speed of motors to ten miles an hour in the borough, the Dover Corporation were on Tuesday notified that the Board will hold a local inquiry into the matter.

AT the last meeting of the Automobile Association of Bengal the following officers were elected:—Dr. Neild Cook, Chairman; Mr. Oakley, Vice-Chairman; Mr. Rolfe, Hon. Secretary; to the Committee Messrs. E. S. Martin, Dent, Birkmyre, Whiteway, and H. Marah were elected.

THE Side-slip Trials of the A.C.G.B.I. will start on the 18th prox., with a 1,000 miles Endurance Test. On completion of this, tests will be made on the track of the new Clement-Talbot works near Ladbroke Grove, W. A number of observers will be required for the Endurance Test.

Digitized by Google

MOTORING AND HEALTH.

AMONG doctors motoring seems to have been welcomed both on account of the facilities it provides for paying the maximum of visits in the minimum of time, and also because of the invigorating effects of a rapid spin through the country. Sir Henry Thompson and other leaders of the profession have borne testimony on this point, and now Professor Hugh Galt has been giving the members of the Western Section of the Scottish Automobile Club what he describes as "the medical aspect of motoring." Life in a city, it was pointed out, resulted in the absorbing into the system of various poisons which made themselves felt in the form of malaise, biliousness and other similar troubles usually ascribed by the medical profession and laymen to a man being in the condition known as "run down." For this condition a motor-car run was of great value. It stimulated the kidneys, the liver, and to a less extent the bowels, and the increased circulation had the effect of removing from the system the poisons thus released. Motoring, according to the professor, had the effect of increasing the circulation of the blood, the heart's action being accelerated with a corresponding oxygenizement of the blood usually from air of the purest kind.

Of course there must be some regard to the constitution and health of the person riding in a motor-car. These very qualities inspired in anyone of sound health might be inadvisable, and even harmful, to a person of impaired heart or delicate health, unless taken with a due regard to the condition of body. But ordinarily to a person of fairly good health the value of automobilism is apparent. After a week's hard work of a sedentary character there is nothing so re-invigorating as a brisk motor trip of many miles, the change of scene and the contact with the fresh air having a most beneficial effect on the whole system. Just as motor ambulances will soon be recognised as part of the equipment of every ambulance station, so will motor-cars be considered a necessary feature of every convalescent home. Patients in such institutions will find their recovery hastened by automobile rides, under, of course, medical advice.

During the discussion at the Scottish Club Dr. Robb raised the question of the effect of motoring on insomnia, and Professor Galt extolled motoring as an absolutely unfailing specific for that distressing complaint. The brain cells were invigorated by the increased circulation; the run through the pure air had the effect of soothing the irritated nerve centres, and the insomnia patient who had gone through this experience in the forenoon, and proposed seeing the sights of the town in the afternoon, usually saw the sights of the town in his dreams while sound asleep in the smoking-room of the hotel. The advantages of this, or any other really interesting open-air hobby; the ability to get almost immediately change of air and change of scene; the evils of monotony on both mind and body, but especially the mind; and the mental training in the direction of resource and self-reliance were all referred to and commented on in a way that should cause many people to regard the motor-car from at new aspect.

But there are points in connection with this view of the motor-car which should not be ignored, viz., the effect of motoring on the eyes, and the want of exercise associated with the pleasures of driving an automobile. Of course, in the early days of the modern motor-car, the vagaries of the vehicles then in use provided plenty of opportunity for enforced exercise in the form of mounting and re-mounting to attend to matters that would go wrong, and to difficulties that would arise without any apparent cause. But those times are past and punctures provide the main excitement of that kind with which the motorist is entertained while riding. And after a drive of many miles the limbs become stiff and cramped. Under those circumstances Sir Henry Thompson recommends that "opportunities should be found once or twice during a long journey of say, seventy or eighty miles, to take a short but smart walk for a few minutes to keep the muscles in order, and make the blood circulate through them." Care, too, should be taken to secure protection against wind and wet by the adoption of the special garments to which so many leading tailors have given close study of recent years. As to the eyes, the use of goggles becomes absolutely necessary when any great speed is attained on the road, especially when roads are dusty and winds are lusty.

These reflections should encourage those who have not yet committed the plunge into the car world to take advantage of the early spring for trial runs, so that they may obtain their automobiles in full time for the summer season, when they can realise for themselves the health-giving pleasures of the motor-car.

The arrival at a Poseda causes excitement on the part of the Natives.

At the Puerta del Sol, in Madrid.

MOTORING IN SPAIN. *La France Automobile.*

A SQUAD of about a dozen men of the Army Service Corps from London and Chatham have gone to Granton to study the mechanism of the new Army motor lorries.

CONTINENTAL NOTES.

THERE will be one neutralisation less on the Cup course now that the route from Oberursel to Saalburg has been altered. Instead of leading through Oberstedten and Dornholzhausen, the Homburg Schlosspark and the Glockensteiner Weg are now to be taken in. The first and original road was the shorter and more direct one, but was twice neutralised, whilst the longer way about will only have the one neutralisation of the Homburg Schlossweg. It is now stated that the drivers of the three Austrian cars will be Warden, Werner, and Braun.

◆ ◆ ◆

THE proposed automobile tax at Frankfort-on-the-Main has been averted, thanks to the efforts of the Frankfort Automobile Club.

◆ ◆ ◆

THE automobile *fetes* at Cannes this week are being favoured by splendid weather, and are so far a great success. On Sunday a gymkhana was held, and on Monday the programme included a hundred kilometres touring test from Cannes to Grimaud and back, and an interesting hill-climbing contest, in which the following took part:—M. Gallice (12-h.p. Clement), M. Burton (60-h.p. Mercedes), M. C. Loubet, (10-h.p. Peugeot), Doctor Durand (22-h.p. Mors), M. C. Quinson (12-h.p. Gladiator), M. C. Mounier (8-h.p. Renault), M. Delaunay-Belleville (35-h.p. Panhard), M. Rouff (20-h.p. Rochet-Schneider).

◆ ◆ ◆

ANOTHER test of anti-skidding tyres is being organised, consisting on this occasion of a run from Paris to Nice and back. A start will be made on the 30th inst. From the 4th to the 7th April the vehicles fitted with the competing devices will be exhibited in Nice and Monte Carlo, the return journey to the French capital being fixed for April 8th.

◆ ◆ ◆

THE Oberpfalzischer Automobil Klub has just been formed at Regensberg to encourage the automobile movement in the Upper Pfalz district of Germany.

◆ ◆ ◆

THE commission appointed by the Italian Ministry of Public Works to inquire into and report upon the question of automobile regulations in Italy recommends (1) that the speed in towns and villages shall not exceed 7½ miles an hour; (2) that in open country no speed limitations be fixed, motorists to travel at any speed they may deem prudent; (3) that motor-cars shall show a white and not a red light at the rear, and (4) that a stricter examination for driving licences be enforced.

◆ ◆ ◆

AT a meeting of the Technical Committee of the A.C.F. the commencement of the Concours de Carburetters was fixed for May 1st.

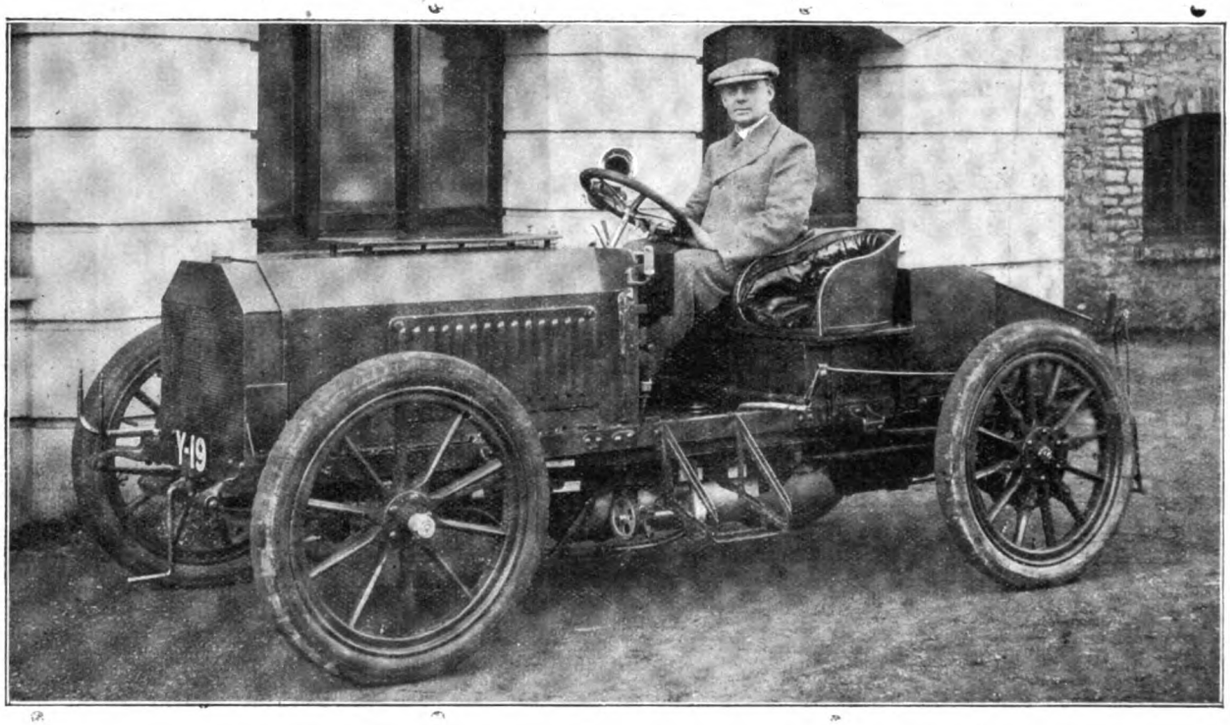
◆ ◆ ◆

THE question of the speed of automobiles has lately been raised in the Portuguese Parliament, and it has been decided that it must not exceed 18½ miles per hour in open country, and 5½ miles in towns and villages.

◆ ◆ ◆

IN our last issue we were only able to mention that the highest number of points in the recent anti-skid trials organised by the Automobile Club de Seine-et-Oise was gained by the Gallus ferré device of M. Edeline. The general classification according to the points gained by each device is as follows:—1. Gallus ferré (395 points); 2. L'Empereur (368); 3, Gallus demi-ferré (361); 4. De Fornier (345); 5. Bergougnan (366); 6. Fouilloy (320); 7. Durandal (310); 8. Lucas (290); 9. Houben (284); 10. Clerget (251); 11. Excelsior (250).

The awards are:—



CATEGORY A. *Removable anti-skid devices.*—1. L'Empereur; 2. De Fornier; 3. Fouilloy; 4. Durandal; 5. Houben; 6 Excelsior.

CATEGORY B. *Anti-Skid tyres.*—1, Gallus ferré; 2, Gallus demi-ferré; 3, Bergougnan; 4, Lucas; 5, Clerget.

CATEGORY C. *Smooth Tyres fitted with anti-skid devices.*—1, Eyquem; 2, Moche; 3, Sainsbury.

CATEGORY D. *Non-skids for motor-bicycles.*—1, Bergougnan; 2, Durandal; 3, Lucas; 4, Billet.

Some of the competitors were not classed by the jury, owing to accidents other than to the anti-skid devices themselves. This applies to the Chameroy, which is being permitted to complete the trials; to the Samson tyre and the Billet tyre, both the cars on which these tyres were fitted having continually broken down, thus preventing the tests being completed.

Mr. John Hargreaves, Templecombe, on his 65-h.p. Napier Car.

This enthusiastic sportsman has lately received the 100-h.p. Napier racing car, which he will drive in the eliminating trials for the English team for the Gordon Bennett Race. If successful in the preparatory event it is his intention to take part in the "Motor Derby," after a course of racing practice on Continental roads.

NEW MOTOR-CAR REGULATIONS.

THE new regulations of the Local Government Board with regard to the use and construction of motor-cars have been issued this week. According to these, the width of cars is now permitted up to seven feet two inches.

Every vehicle exceeding two cwts. in weight unladen, drawn by a motor-car, is required to have a brake and shall carry a person competent to apply the brake efficiently.

One interesting clause obviously refers to tri-cars and other additions to motor-cycles. Two independent brakes have to be fitted to motor-cars, of such efficiency that the application of either to the motor-car shall cause two of its wheels on the same axle to be so held that the wheels shall be prevented from revolving. The exception is in the case of a "motor-car having less than four wheels." This condition shall apply as if instead of two wheels on the same axle, one wheel was referred to.

Article IV. of the new regulations contains one or two new clauses, and drivers must not now travel backwards for a greater distance than may be requisite for the safety "or convenience" of the occupants of the car, and of other traffic. Motorists, too, must drive with a full view of the road ahead, and if they quit the car, must take precautions against it being started in their absence.

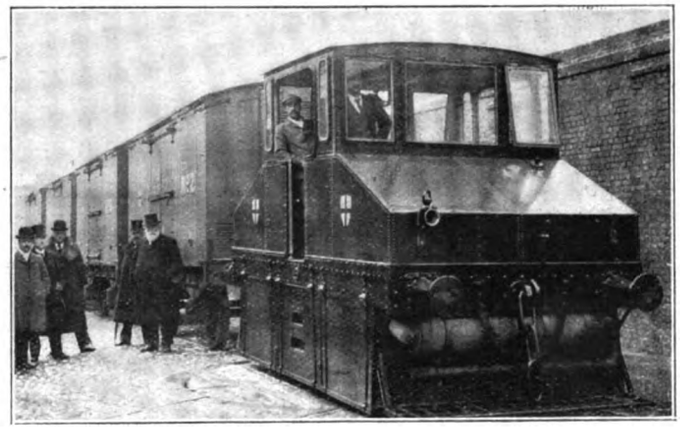
The question of stopping the vehicle has evidently been reconsidered by the Local Government Board, and motorists now need only stop on the request of a police constable in uniform, or of any person having charge of a horse.

In the circular accompanying the regulations, there is an appendix with reference to the notices and sign posts to be put up under Section 10 of the Motor Car Act. These have been previously referred to, but may be summarised on the present occasion as follows:—For the ten mile, or lower limit of speed, a white ring, 18 inches in diameter, will have to be placed upon a post not less than 8 feet from the ground level, with a plate indicating the limit in figures. For the total prohibition of motor-car traffic, a solid red disc, 18 inches in diameter, will have to be provided; a hollow red equilateral triangle with 18 inch sides will indicate caution at dangerous corners, cross roads, etc., and two of the other notices under the Motor Car Act will require to be set forth on diamond-shaped boards.

THE Peterborough Motor Company have lately extended their works.

AMONG the events that will attract motor-cyclists to the Exhibition at the Agricultural Hall next week will be a meeting of the Auto-Cycle Club, at which Mr. Victor Hart will read a paper on "Some Suggestions for the Auto-Cycle Club's 1,000 miles trial." The meeting will be held in one of the rooms at the Hall on Friday, the 25th, the chair being taken at 7 p.m. There should be a good muster of members of the club, who will receive invitations for the meeting from the energetic secretary, Mr. F. Straight.

THE R. L. Engineering Company, Limited, of Verulam Street, Holborn, W.C., is bringing out a new car fitted with a 3½-h.p. Rulex engine at a price which is exceptional, even in these days of cheapened light cars. They have also one fitted with a 4½-h.p. engine. These cars are equipped with a patent two-speed gear and free engine, and can be geared up to forty miles per hour. They will be at the Exhibition. The R. L. Motor Engineering Company, Limited, have well-equipped works, and are going thoroughly into the automobile industry.



THE opening run of the season of the Motor-Cycling Club took place on Saturday last, the destination being Brighton. The meeting place was at Purley Corner, and there were quite fifty machines assembled just before the start. Excellent running was made to Crawley, where a fifteen minutes' halt was made. One or two members fell out on the latter part of the run to effect trifling adjustments, but practically everyone got into Brighton well before lighting-up time. In the evening a dinner was held at the Old Ship Hotel, at which about forty members were present.

A NEW PETROL LOCOMOTIVE.

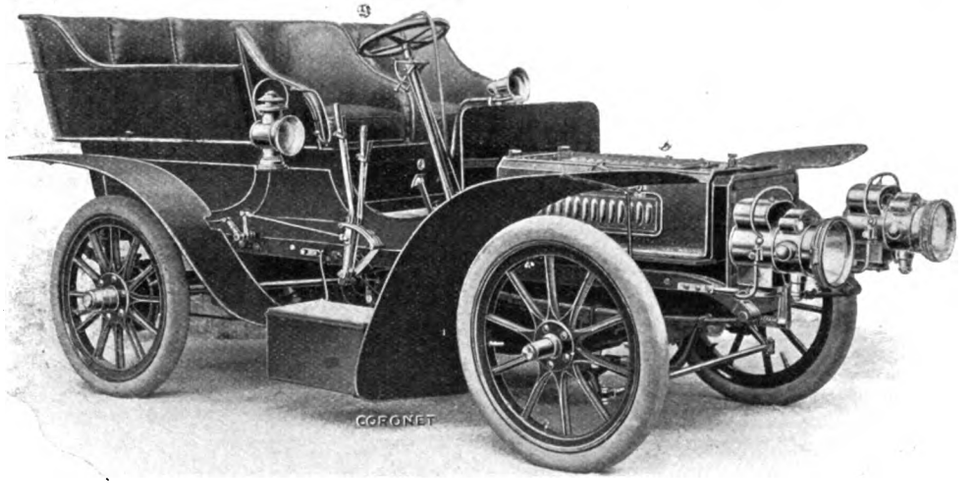
THE locomotive shown in the accompanying illustration has been designed and built by the Maudslay Motor Company, Limited, of Coventry, to the order of the City of London Corporation, for the special purpose of drawing trucks on a standard gauge line between the Corporation meat market and the London, Brighton, and South Coast Railway sidings. The full load consists of four trucks, weighing when loaded about fifty tons. The maximum gradient is exceedingly stiff, being 1 in 36. As the line to be traversed runs partly through the streets and partly through the market, the locomotive is geared to travel at a slow speed only, and has two speeds of 2½ and 5 miles per hour respectively in each direction.

The petrol motor is similar in design to the Maudslay Company's standard pattern, and has three cylinders, 9 in. bore by 9 in. stroke, and develops 80-b.h.p. at 450 r.p.m. Half compression cams are fitted, and for greater convenience an 8-h.p. single-cylinder engine is provided for starting purposes. The water and petrol tanks are of sufficient capacity for a whole day's run, and the motor is cooled by a large tubular radiator fitted with a fan. The mechanism is all covered in to conform with the Board of Trade regulations. The weight of the locomotive complete is about twelve tons.

Westinghouse brakes are fitted in addition to the ordinary hand brakes, as also a sanding apparatus for use when the streets are greasy.

The official trial of this locomotive took place on the 29th ult. The trucks shown in the photograph were loaded with paving stones to bring them up to the contract weight (fifty tons). The locomotive drew them all over the system with perfect ease, and it was evident to those present that it would have been capable of drawing the same load at a much higher speed or a much heavier load at the same speed. The trial included stopping and re-starting on the steepest gradients. The running of the locomotive, and especially the ease with which it was controlled and reversed, gave complete satisfaction to everyone concerned.

MOTOR boats will be among the attractions of the Berner's Hall at the Exhibition next week.



THE Imperial Motor Company, Limited, has been registered with a capital of £10,000, to adopt agreements with Messrs. A. Giovanelli, J. S. Stewart-Wallace and A. Carlisle-Herts, and to carry on the business of manufacturers of and dealers in motor- or other cars, wagons, cycles, and vehicles of all kinds, etc.

IN order to meet the demand for a light two-seated car at a popular price the Duryea Company are putting on the market a two cylinder 8-h.p. vehicle, which will embody their well-known features of central engine and direct drive with single chain on to a live axle. Two speeds and reverse will be available by means of a concentric gear on the engine shaft. The company are hoping to have one of the new vehicles on view at the Agricultural Hall Show next week.

Digitized by Google

THE "CORONET" PETROL CARS.

THE CORONET MOTOR COMPANY, LIMITED, of Coventry, are bringing out two new types of petrol cars of 8-h.p. and 16-h.p. respectively. The 16-h.p. car is fitted with one of the "Coronet" four-cylinder water-cooled governed engines; each cylinder of which is a separate casting with its water jacket. The bore is 3¾ inch and the stroke 4⅜ inch. The pistons are of good length and are fitted with three eccentric rings. The crank shaft has a bearing between each throw of the crank. The valves are of large diameter and mechanically operated by one cam shaft, which is supported by a central bearing, and, together with its gear wheel and governors, runs continuously in oil in a dust proof case. Two large inspection plates are fitted in the lower half of the crank case. The normal speed of the engine is 1,000 revolutions per minute. Although nominally rated at 16-h.p., the brake power on test is 20 to 22-b.h.p., with the motor running at normal speed, and 25 to 27-b.h.p. at 1,400 revolutions per minute. The power from the motor is transmitted to the gear-box through an internal leather-faced clutch entirely free from end thrust either to the motor or gear box, whether the clutch is "in" or "out," a universal joint being arranged between the gear box and clutch. The gear gives three speeds forward and one reverse, all controlled by one lever. The top speed is a direct drive with all the gear wheels out of mesh. The change gear offers some novel ideas of much interest; it is of the ordinary sliding type, but the sliding is done on all-round shafts, there being no square shaft or wheels sliding on tongues or rings, an arrangement enabling all parts to be accurately ground after hardening, and ensuring, if properly fitted and meshed, as thoroughly silent a gear on all speeds as is possible! The transmission from gear box to the road wheels is by cardan shaft and live axle. The road wheels are mounted on the outer tube of the axle; the driving shaft from the differential runs through this tube and drives the hubs through steel star clutches firmly fixed to the driving-shaft; by this method there is claimed to be no possibility of the road wheels spreading. The differential gear in the rear axle is of the spur wheel type. The wheel base of the car is 7 ft. 10 in., and the tread 4 ft. 3 in. The frame is of hydraulic pressed steel. Three brakes are fitted—one on the differential and one each acting on drums connected with the rear road wheels, all brakes being of the same size. The steering gear is the Coronet Company's special irreversible type. The car is fitted with phosphor bronze bearings, the makers having adopted these in preference to ball bearings. The body work of the car is by the Coronet Company, and is upholstered in best leather. The 8-h.p. car is similar in design to the 16-h.p. and is fitted with a governed engine giving 10-h.p. on the brake at 1,200 revolutions.

The Coronet 16-h.p. Car.

MOTOR-CYCLING NEWS.

ONE of the most remarkable charges yet heard against the motor-bicycle is that of farmers out in Indiana, who complain of the motor-cycle riding of a young priest, the Rev. Father Adam Baron, of Linton, Ind. The agrarians say that the machine frightens the cattle in the fields and they become so excessively nervous that they lose flesh! The Rev. Father Baron is an enthusiast both in the work of his calling and in respect to the motor-cycle. He has charge of two parishes fifteen miles apart, and by virtue of using a motor-cycle he is able to preach at both places every Sunday. Father Baron has become popular with his parishioners because of his enterprise, but his dash when on the road has made him unpopular with the farmers, who are threatening suit for damages on the ground that the loss of flesh by their cattle caused by nervousness, due to fright at the motor-bicycle, has resulted in a depreciation of the market value of the animals.

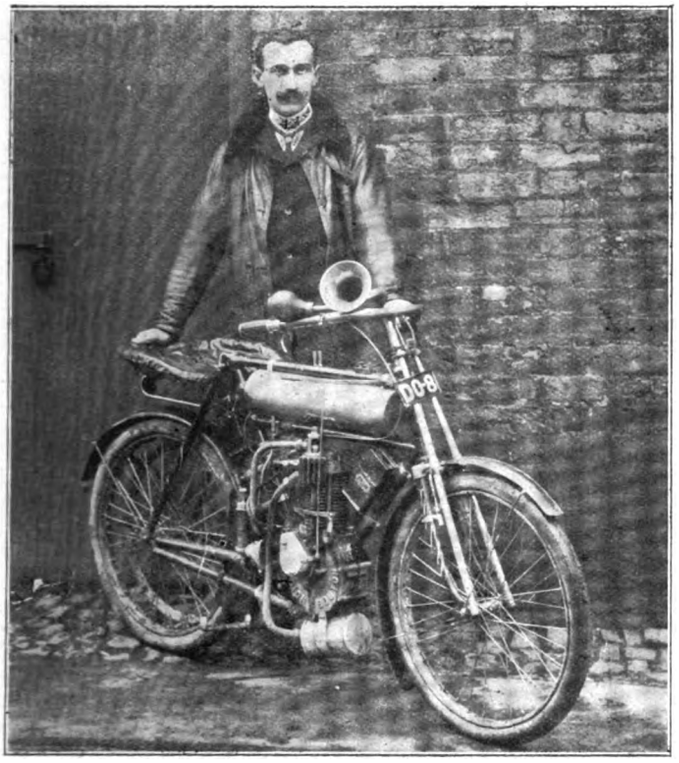
◆ ◆ ◆

NOW that the riding season is commencing a word of warning may be given to those riders who are this year making their debut in the motor-cycling world against being too venturesome. The art of "tap-twiddling" may be quickly learned, but that of riding through traffic needs much practice, and until a rider feels that he has full control over the machine it will be well for him not to indulge in high speeds. The *debutant* is already more than probably a cyclist, and may imagine the management and control of the motor are the only things he has to learn. There is, however, a considerable difference between the average speed attainable on a bicycle and a motor-cycle to become accustomed to which needs more than a day's practice. We have been led to make these remarks by the fact that on Saturday last a boy named Gredge, aged 16, whilst riding his motor-bicycle at Ilford, collided with a van. The impact of the collision smashed the machine and threw its rider with such force that he was picked up unconscious and taken to the London Hospital, where he was found to be suffering from severe abdominal injuries.

◆ ◆ ◆

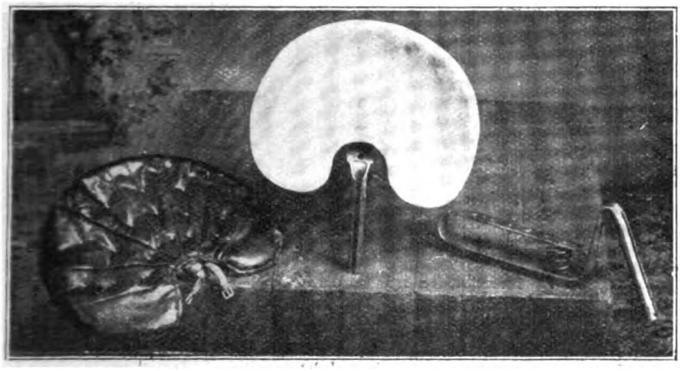
"O. L." WRITES:—"I have not lately seen any correspondence in the *Journal* on the subject of clutches for motor-cycles. They are not an absolute necessity with one cylinder motors, but now that there are two and four-cylinder motors, I think that it will be absolutely necessary to have a free engine. I should very much like to hear other correspondents' opinions on this subject."

◆ ◆ ◆



A MOTOR-CYCLE tour on the Continent is being arranged by the C.T.C. for Easter, and every effort is being made to render the trip thoroughly enjoyable. The tour will extend from March 30th to April 6th, the party crossing from Southampton to Havre on the night of the 30th inst., returning from

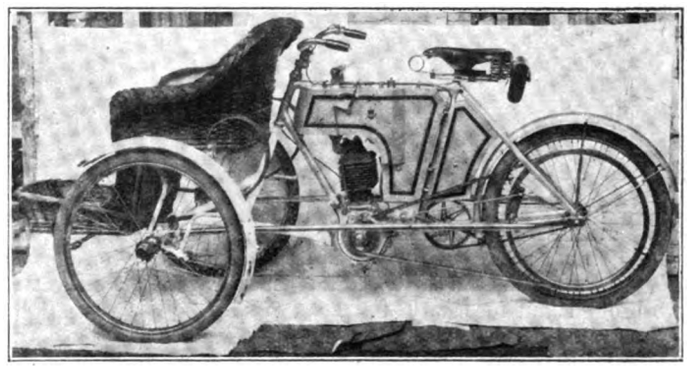
Digitized by Google



France on April 5th. The chief places to be visited will include Trouville, Caen, St. Lô, Coutances, Granville, Avranches, Mont Saint Michel, Domfront, Falaise, Lisieux, Brionne, Bourgtheroulde, Rouen, and Caudebec.

◆ ◆ ◆

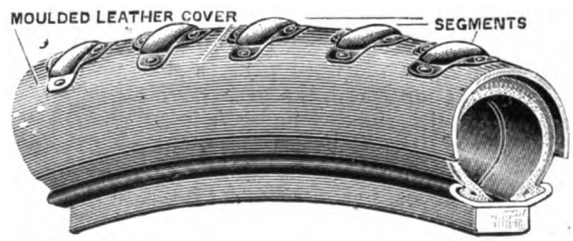
We are indebted to Mr. Richard W. Curtis, of Holbeach, Lincolnshire, who is acting as agent for Mr. Robert Cooke, of Decoy Farm, Spalding, for the accompanying photographs of an



improved seat for motor-cycles. It consists of a piece of spring steel forged to a special shape, being made semi-circular, and is inserted into that part of the frame which usually contains the ordinary seat pillar post. Being made concave, it admits of the use of the usual saddle post at the same time, if required. An auxiliary steel spiral spring is connected with the top and bottom of the larger spring for strengthening purposes. A well-dished seat made of aluminium or suitable metal or material is attached to the spring by means of bolts and nuts in such a way that it can be adjusted to any desired position, the seat being

upholstered or padded in different styles. The first illustration shows Mr. Cooke with his motor-bicycle, to which is attached one of the improved seats. In the second picture, the various parts of the seat are shown separately. We may add that the new seat can be applied without trouble to any make of motor-bicycle. In an interview we learn that Mr. Cooke, originally trained for an engineer, developed into a farmer, and having farms both in Lincolnshire and Norfolk, some fifty miles apart, he found motoring essential. He now rides regularly, often upon the roughest roads and grass fields, and finds no inconvenience, thanks to the new attachment. The seat, which is broad and comfortable, causes no inconvenience in mounting or pedalling. The spring and saddle will be on view in the Berner's Hall at the Show at the Agricultural Hall, which opens to-day (Saturday).

◆ ◆ ◆



The Rex Motor Manufacturing Company's latest production in the way of two-seated motor-cycles is shown below. It is known as the "Triette"; the motor power is supplied by a standard "Rex" engine of 3¼-h.p. A notable feature of this motor is the baffle-plate silencer incorporated with the exhaust valve chamber, and recently this construction has been further improved by the addition of an air passage between the cylinder proper and the exhaust valve chamber, in

order to prevent overheating. The disposition of petrol tank, carburettor, lubricating oil tank, coil and accumulators (two), is somewhat different from any other make of machine. The tank or casing is extended downward almost to the bottom bracket and between the cylinder and seat post. The accumulators and coil are carried in a separate compartment fixed to the rear of the latter, this arrangement permitting of a large petrol storage. The transmission is by V belt; the Rex foot-brake enables the rider to place his foot on the brake lever when riding in the ordinary position. The brake is extremely simple, consisting merely of a bell-crank lever operating through a direct connecting rod on a pivoted shoe, which in turn is brought in contact with the inner surface of the belt pulley.

◆ ◆ ◆

Herewith we illustrate Edwards's newest patent non-skidding device, as applied to a motor-cycle tyre. It will be exhibited in this form and also as applied to motor-car tyres, at the forthcoming show at the Agricultural Hall. It will be seen that it is an adaptation, in metal, of the principle of the original Edwards' non-slipping cover for bicycle tyres which was so popular some years ago. Experiments and trials extending over

many months have demonstrated that motor-cycles and cars fitted with this tyre are absolutely safe from skidding under all conditions of road surface. The improved non-skidder consists of a specially prepared toughened chrome leather cover, moulded so as to fit all sizes and makes of tyres. On the tread of this cover steel segments are fixed with bifurcated rivets at suitable intervals.

◆ ◆ ◆

The committee of the Auto-Cycle Club have decided to make the use and fitting of silencers optional in motor-cycle races held in enclosed grounds.

The Alldays Three-seated Car.

THE ALLDAYS LIGHT CAR.

MESSRS. ALLDAYS AND ONIONS, LIMITED, in response to enquiries for a small car of rather more power and size than their well-known "Traveller" voiturette, have brought out for the 1904 season the "Alldays" 6½-h.p. light car illustrated herewith. In designing this vehicle care has been taken to make every part as simple as possible, whilst providing ample strength and wearing surfaces to every working part. Smooth and comfortable running is ensured by the use of extra long and flexible springs. The frame is constructed of channel steel, bent in one piece, and stayed by two cross sections, the engine and gear-box being bolted to two longitudinal members riveted to the front and two cross sections of the frame. The motor, of the vertical single cylinder type with outside fly-wheel, developing 6½-h.p., is fitted with mechanically-operated interchangeable valves. The fly-wheel forms the outer portion of the friction clutch, which is leather faced, and designed to eliminate all end thrust when driving. The cooling water is carried in a combined tank and radiator placed in the front part of the bonnet, the circulation being maintained by a slow-running pump driving direct from the cam-shaft, to which it is attached by a flexible coupling. The crank case is made in two halves, the upper half having extended arms for bolting direct to the frame of the car; the lower half can be readily detached, and is also provided with a bottom inspection plate which provides for making adjustments to the connecting rod. A universally-jointed shaft is fitted between the engine and gear-box, in addition to the one between the gear-box and the rear axle, thus preventing any undue strains on the bearings of the engine or the gear shafts, which may be caused by any springing or distortion of the frame. The gear-box is arranged for two forward gears and a reverse, with a direct drive on the top speed, the gear wheels being of ample width to ensure quiet running and a minimum of wear. The rear axle is of the "live" type, running in an oil-tight dust-proof casing, fitted with a spur-gear differential instead of the usual bevel type. The two halves of the axle run in plain bearings, but ball-thrust bearings are provided for taking the side thrust due to the bevel drive. The brakes are of the expanding metal-to-metal type, that on the countershaft being operated by a pedal, which also disengages the clutch, while the one on the differential is operated by a hand lever at the side. A second pedal is provided to disengage the clutch only, while the change gear is controlled by a side lever. The petrol and lubricating oil-tank is mounted at the rear of the dashboard, and holds sufficient petrol for a run of about 130 miles, while the lubricating oil capacity is equal to a run of 250 miles. The levers for controlling the ignition and mixture are conveniently mounted on the inclined steering column. Any suitable type of body can be fitted, but of the two standard types, one is a body with a phaeton seat for two passengers, having a large and roomy platform at the back for luggage, and underneath this a cupboard for carrying an extra tyre, etc.; and another has a three-seated body. This car, which is shown in the accompanying illustration, at first glance appears to be of the usual tonneau order, but a closer inspection reveals the fact that it possesses only one front seat—the driver's seat—and that the space usually occupied by a second seat is left vacant and forms a passage by which to enter the tonneau from the dash platform, in place of by a door at the back. The car, which appears to be of sound construction and design, will be on view at the Exhibition at the Agricultural Hall.

A COMMERCIAL TRAVELLER'S CAR.

MESSRS. DE DION, BOUTON AND COMPANY have lately completed a car for the use of one of the travellers of Messrs. Michelin and Company, the well-known tyre manufacturers. So far as the *chassis* is concerned this is a standard 8-h.p. De Dion; it is in the carriage work that the special features of the vehicle lie, as will be seen from the illustrations on pages 53 and 54. In place of the usual tonneau, the rear part of the body consists of a neatly finished chest having double doors, one dropping down and the other lifting up. The chest itself is divided into four compartments, thus enabling the various classes of samples carried to be separated and conveniently arranged. As the car is to be used in all weathers, the front seat is fitted with a special hood which projects forward a greater distance than usual, so completely protecting the driver and passenger from rain.

THE Speedwell Motor and Engineering Company, Limited, have issued a booklet entitled "The Pleasures of a Light Car," which deals with the advantages of the popular Speedwell light cars.

OWING to the attention drawn to the Sainsbury Anti-Skidders by reason of their entry in the recent French competition, many enquiries have reached Sainsbury's Anti-Skidders, Limited. From the experience gained in these trials they are perfecting the device by incorporating several minor improvements. These modifications will be embodied in the Anti-Skidders they are running in the English trials, at the conclusion of which they hope to be able to present to the motor public an article more satisfactory in every way than those hitherto supplied.

HERE AND THERE.

It is reported that the Cockerill Company, of Seraing, Belgium, is about to take up the construction of motor-cars.

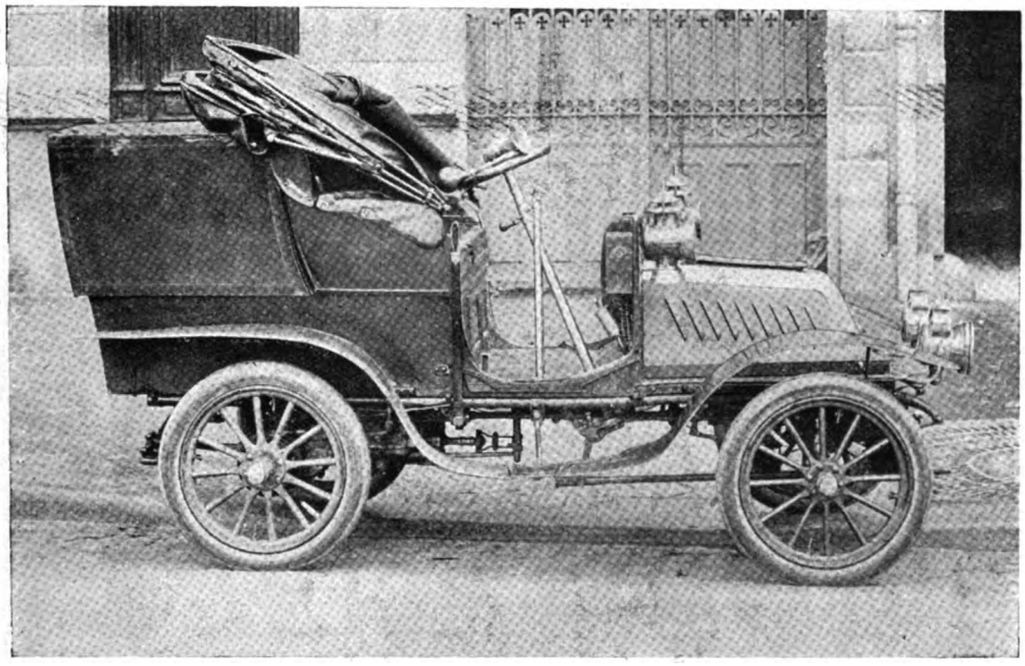
The Southern Motor Club has signed the affiliation agreement with the A.C.G.B.I., in accordance with scheme 2.

The British Automobile Commercial Syndicate, Limited, are making a special feature of the teaching of "Driving and Repairing" of motor-cars.

The International Westrumite, Limited, is the title of a company formed with a capital of £320,000 to adopt an agreement with Mr. L. S. Van Westrum.

Dr. Hopkins Walters, who took the initiative with the Reading Club in connection with the recent federation proposals, has been elected an honorary member of the Southern Motor Club.

Sir David Salomons has offered to present to the London County Council, for placing in a prominent position in London, one of the earliest locomotives in use in the country. It is the Invicta, an engine constructed by Stephenson, and of the same type as the Rocket.



The engineering students of McGill University, Montreal, Canada, are constructing a 12-h.p. petrol motor-car.

The Marquess of Anglesey has, at Newport Pagnell County Court, been ordered to pay £15 and costs for injuries caused by his motor-car to two bullocks belonging to a local farmer.

J. S. Critchley, Ltd., have taken over the Stanley Works, 306, King's Road, Chelsea, S.W., and will carry out any motor-car work either in the shape of repairs or alterations. Special provision will be made for experimental work.

The report of the directors of Vickers, Sons, and Maxim, Limited, for 1903 states that the expectations expressed in last year's report with regard to the Wolseley Tool and Motor-Car Company have been fulfilled, and there continues to be a large demand for the motor-cars manufactured by them.

Messrs. Horsfall and Bickham have sent us a copy of their new catalogue of "Horbick" cars, which for 1904 are being made in sizes from 6 to 14-h.p., with various types of bodies. The list gives detailed illustrations of the new popular-priced 6-h.p. "Horbick Minor" car

The De Dion-Bouton Commercial Traveller's Car. (See page 52.)

The annual supper of the Scottish Motor Manufacturers' and Traders' Association has been held in the North British Hotel, Edinburgh. Mr. John Stirling, the president of the Association, occupied the chair, and was supported by Mr. Paterson, vice-president, Mr. Hewit, Mr. T. M. Sleigh, secretary, Messrs. Spencer, John Wilson, L. Morelli, W. L. Sleigh, Kingsbury, Sangster, and W. Flint. The toast of the Association was proposed by Mr. Hewit, and replied to by Mr. Stirling.

Messrs. J. Rothschild et Fils have received orders to construct a motor-car body with side entrances for Major Courtenay Morgan. This will be the first body undertaken to be built entirely in London. Previously Messrs. Rothschild received all their bodies from the French factory, and they were finished and upholstered at the London works; arrangements have now been made and a staff of French workmen drafted over for the purpose of building all the bodies in England, and exactly similar work will be made in this country as has hitherto been turned out in France.

In their Little Guide series Messrs. Methuen and Co. are including some famous cities, as well as many pleasant counties. The latest volume deals with Rome, Mr. C. G. Ellaby contributing the letterpress and Mr. B. C. Boulter supplying some charming illustrations.

In consequence of the strong opposition to the proposed regulation limiting the speed of motor-cars within the borough of Blackpool to ten miles per hour, the Town Council of Blackpool have, with the consent of the Local Government Board, withdrawn their application.

At a meeting of the Associated Chambers of Commerce Mr. Levenstein (Manchester) proposed:—"That having regard to the great advantages resulting from the extensive employment of untaxed alcohol for industrial purposes, this association is convinced that the retention of the existing duty on pure alcohol for such purposes is a very serious obstacle to the progress of British industry, and that a letter be forthwith addressed to the Chancellor of the Exchequer, asking him to receive a deputation on an early date for the purpose of demonstrating to him the importance and urgency of exempting from duty pure alcohol for industrial use. Mr. Tyrer (London) seconded, and it was carried.

THE Automobile Club of Victoria now numbers 87 members, and an inaugural dinner was being arranged for when the mail left.

THE value of the automobiles and parts exported from the United States during January last amounted to only £17,907, as compared with £22,874 in January, 1903.

A MOTOR CAR service is being established between Kidderminster and Bewdley, with headquarters at Mr. T. W. Bowen's motor house in Mill Street, in the former town.

THE Aberdeen County Council has decided to apply to the Secretary of Scotland for an authorisation restricting the speed of motor vehicles in certain places to ten miles an hour.

MESSRS. W. WATSON AND COMPANY have removed from Hoylake to commodious premises in Newington, Liverpool. Three years ago they ran a public service of motor-cars in Chester, and have been running cars for hire ever since that time.

MR. A. H. BUNNING, of the Rathmore Cycle Depot, Hawthorn, Victoria, has lately completed the construction of a steam car which will develop about 6-h.p. and seat three passengers. The car has a tubular frame and chain drive. The engine is of the twin cylinder type and the boiler is of the wire-bound tubular pattern, tested up to 2,000 lbs. pressure.

A MEETING has been held at Llandaff in connection with the proposed motor-car service from Cardiff to that little city. Although no resolution or definite understanding was arrived at, the explanation of the proposed South Wales and Monmouthshire Motor Omnibus Company, given by Mr. Roberts Jones, solicitor, of Cardiff, proved very acceptable to the meeting.

IN the area of the West Riding (Yorkshire) County Council there have been registered 262 motor-cars and 247 motor-cycles. Four transfers of ownership have been registered, while 13 manufacturers and dealers' general identification marks and 763 licences to drive motors have been issued. The total fees received amount to £554, of which £229 has been for annual fees.

IN connection with the cross-Channel motor-boat race from Calais to Dover on the 8th August a Dover town challenge cup is to be offered.

AN inquiry into the application of the Winchester Town Council to restrict the speed of motor-cars in its district to ten miles an hour will be held at Winchester on Thursday next.

A FLORAL fete will be held at the Royal University, Dublin, on April 14th and 15th, among the attractions being a competition for the best decorated motor-car. For this the Wolseley Company have presented a silver cup.

MESSRS. DENNIS BROS., LIMITED, have sent us a photograph of the new factory they are erecting in Guildford. The extension is a three-storeyed building forming an addition to their present establishment. The ground floor is divided to contain the engine-room, in which is being installed a 75-h.p. gas engine and a Dowson gas plant to drive electric motors, and a large dynamo for lighting the whole building. On the ground floor there is also allotted a large smiths' shop with twelve forges, and a garage with several inspection pits, which is to be confined to adjustments necessary to new cars, when undergoing their test runs. On the same storey is a large mess room and lavatories for the workmen. On the first floor is a large room in which all the stock used in the construction of the cars will be stored. On the same floor is the upholsterers' shop, and an extensive body-building department. The second floor will be used entirely as an erecting shop. An idea of the size can be gleaned from the fact that it will be possible to have over fifty cars in erection at one time. The working area of the new factory is 38,000 square feet; the building is heated by hot water, and is equipped with a large lift giving access to all floors.

THE young Sultan of Johore, who paid an official visit on Saturday last to Mr. Lyttelton at the Colonial Office, is an enthusiastic motorist. His Highness, who drove to Downing Street in a motor-car, accompanied only by a couple of aides-de-camp, is thirty years of age and speaks English with fluency.

Rear View of the De Dion-Bouton Traveller's Car, showing Sample Chest. (*See page* 52.)

SOME USEFUL NOTES.

IT is frequently stated that the valves of a car (inlet and exhaust) are absolutely interchangeable; this is not so. It will always be found that ground surfaces only fit in the places in which they are originally ground.

◆ ◆ ◆

WHEN using a loose starting handle which engages direct on the crank-shaft, it is a good plan to put a little oil on it, as if by any chance the handle sticks a little, it will be carried round when the engine starts.

◆ ◆ ◆

USERS of cars having the Panhard type of clutch which pulls out through the gear box should note that there should always be ¼ in. clearance between the fork and the spring box.

◆ ◆ ◆

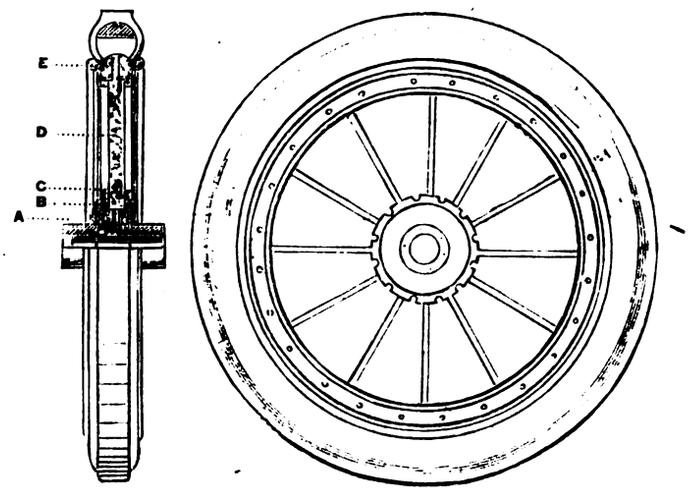
PETROL is the best material for cleaning a dirty plug; wash it well first, and then set fire to the tip, and finally polish up with fine emery paper.

◆ ◆ ◆

THE "Grappler" motor tyres are the subject of a booklet just issued by the Hyde Rubber Works, Limited, of Woodley, near Stockport. Some hints on the use and preservation of tyres are given, an idea of the utility of which may be learned from the following extract:—"It is most essential that a car should be fitted with tyres tested to carry the weight required. A very useful practice is to have a heavier class of tyre upon the back wheels, and the specified ones on the front wheels. When new tyres have been fitted, run the car gently at first for about fifteen minutes, then tighten up the driving bolts, and run on again quietly for a time in order to allow the tyres to get well into their places in the rims. Rubber is highly susceptible to the action of oils and acids, and rapid decomposition will set in if subjected to their influence. If by mishap oil is dropped on the tyres when lubricating the wheels, they should be cleaned immediately. The fabric portion of the tyre is very susceptible to the effect of water. It is for this reason that a puncture that lays bare the fabric is most to be dreaded. The water is quickly absorbed and decomposition sets in. Water sometimes finds its way into the casing owing to the tyres being insufficiently inflated."

◆ ◆ ◆

AN American contemporary gives some useful hints with regard to the care of the painted parts of motor-car bodies. Such delicate work requires a certain amount of attention to keep it in proper condition, and the better the painting the more sensitive it will be to certain conditions, but the more durable it will be if given intelligent care. Water should never be allowed to remain on the paint; it will make a spot wherever it rests, dulling the lustre of the varnish. Warm water and soap are to be avoided as injurious to varnish. A sponge, chamois leather and cold water should be used in cleaning. Sponge off mud, dust, etc., taking care to keep the sponge well cleared of grit, so as not to make scratches, and dry with the chamois leather. There is no objection to using a hose, as long as the water is removed from the paint at once. For brightening up carriage paint that has become somewhat dull there are several good "renovators" on the market. These should be applied with cheese cloth and then rubbed completely off with fresh pieces of the material. The paint should be rubbed until no discoloration of the cloth is produced. This will improve the paint considerably; but disastrous results will follow if any of the renovator is left on.



◆ ◆ ◆

SPARKING plugs frequently short-circuit across the porcelain; this can always be stopped by smearing a little oil on the latter.

MESSRS. OCKS, LIMITED, has been registered with a capital of £12,000 to acquire the business of manufacturers, importers, vendors and exporters of motor-cars and accessories now carried on by Mr. H. L. Cocks at 77 and 78, High Street, Marylebone, W., as La Société des Automobiles Francaises, and to carry on he said business.

A NEW MOTOR-CAR ROAD WHEEL.

FOR a long time considerable attention has been devoted to the matter of increasing the lateral stability of road wheels for motor-vehicles, and numerous new types or methods of construction have from time to time been brought under our notice. The illustrations given herewith depict an improved road wheel which is made under Harvey's patent by Messrs. Ireland and Johnson, Wolverhampton. It will be seen that the wheel proper is of wood, as usual, the nave and spokes, however, being reinforced by, or rather encased in, metal sheaths. The hub proper consists of two metal flanges, A, mounted upon a bearing sleeve of bronze, having between them the wooden nave, B. Into the latter are recessed the reduced ends of the spokes, through which and the flange fixing bolts are passed, as shown in the drawing. The tubular steel casing, C, of the spokes is also let into the nave for a certain distance, so that the greatest strength possible can be obtained at the junction of the spoke with the nave. In order to give still greater strength to the spokes, a metal casting, C, is placed around the nave, with its inner periphery slightly below the edges of the hub flanges. At their outer ends the wooden spokes, together with their steel casings, are recessed into the felloes of the wheel. This construction, in conjunction with an oval section spoke, gives an exceedingly strong wheel, particularly laterally, so that the risk

A—Metal Flange.
B—Wood Nave.
C—Metal Ring.
—Wood Spoke.
—New Flange Fix

of collapse in turning sharply or when travelling round bends at speed is very much reduced. It is claimed to be impossible to break the spokes or buckle their casings.

SEVERAL entries have already been received for the races to be held during the automobile week a Ostend; they include Baron de Caters, who will drive a Mercedes, Messrs Hautvast and Augieres (Pipe), Coppee (Panhard), H. Fournie and A. Fournier (Hotchkiss).

THE drivers of the various cars in the eliminating contest for the French Gordon Bennett team will, it is expected, be as follows:—

De Dietrich: Jarrott, Baron de Forest, Gabriel.
Panhard-Levassor: H. Farman, Tart, Teste.
Mors: Salleron, Lêger, Lavergne.
Turcat-Mery: Rougier, de la Touloubre.
Gardner-Serpollet: Le Blon, Chanliaud, Pelzer.
Gobron-Brillie: Rigolly, Duray, Alex. Burton.
Darracq: Baras, Béconnais, Wagner.
Clement-Bayard: A. Clément, Hanriot, Guders.
Georges Richard: Stead, Théry, Caillois.
Hotchkiss: H. Fournier, A. Fournier, X...

CORRESPONDENCE.

THE AUTOMOBILE AND CYCLE ENGINEERS' INSTITUTE.

To the Editor of *The Motor-Car Journal.*

Sir,—For some time past a large proportion of the members of the Cycle Engineers' Institute have held the opinion that the time has come when the Institute should endeavour to widen its sphere of influence by embracing all forms of road locomotion. Probably the fact that a number of its most influential members—many of whom were founders of the Institute—have now entered the automobile business has been an important factor in the movement. It is only necessary to mention the names of some of the members of the- Institute, such as Mr. Austin, of the Wolseley Tool and Motor-Car Company, Mr. Craig, who has had so much to do with the design of more than one well-known car, and Mr. Garrard, of the Clement Talbot Co., who have attained important positions in the profession of automobile engineering, to show that in including the younger trade the Institute is following its natural line of development and evolution.

It is understood that at the general meeting, to be held in the near future, the council will recommend members to adopt a resolution to the effect that the name of the society be altered to that of the "Automobile and Cycle Engineers' Institute." The step has been taken after considerable deliberation and frequent consultations with engineers directly and exclusively engaged in the trades connected with the motor business, and it is believed that some of the official organizations connected with the latter business are of opinion that the proposed extension at the Cycle Engineers' Institute will meet the requirements of automobile engineers to a more complete extent than would be possible if an entirely new institute were formed, which, under existing circumstances, would only include a portion of the men interested in road locomotion. It is assumed that, in the event of the resolution being passed, more or less radical alterations will be made in the constitution of the body, in order that the younger trade shall be represented in an adequate manner on the council and official positions of the re-constituted body.—Yours truly,

A. S. Hill,
President of the Cycle Engineers' Institute.

BENZ v. LIGHT CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—I almost regret that I wrote my first letter, as the gentleman owning the car I referred to cannot spare the time to give the information which my letter has created a desire for. He says that to do it thoroughly would require several drawings and much technical description; that even then not one engineer in five, nor one amateur in five hundred, could do the job successfully, and that if a mess were made of it he would be blamed. I will try to describe what I remember of the improvements that were made in the car. I spent my holidays last summer with the owner, and I was desirous of learning the "whys and hows" of things with the view of getting a motor-car myself.

The alterations consist of a new valve chamber casting to admit of larger valves. The inlet valve is made 1¼ in. diameter, double the area of the former one; it requires a shorter lift and is mechanically operated. The exhaust valve is also 1¼ in. in diameter. The port hole in the cylinder is also made twice the area, and the compression chamber was reduced to give greater compression. Larger exhaust pipes and a very large silencer (five times larger) were fitted, as well as a Star carburettor, which contributes greatly to the power and to the economy of petrol when once it is started. At first it was very difficult to start the engine with this carburettor (which is its great fault); but this has been overcome, so that the engine is now quite easy to start. We have now got a very powerful engine—the power is more than doubled. Formerly, the engine would run, when the car was standing, at about 600 or 700 revolutions per minute; but putting a little pressure on the fly wheel with a handful of cotton waste would instantly reduce it to half, thus showing that the power was lost in internal work and heat. Now it will run at 1,200 revolutions and all the pressure you can put on it in the same way will not appreciably reduce the speed. There is less heat in the jacket-water, and it can be run as slowly as before with less liability to stop. It can be run at a high speed, too, almost without noise, except the clicking of the cams. At the highest speed it will run at the vibration is terrible. The vibrations are not large in amplitude; they are very small, but very penetrating, and will start every bolt and nut about the car. This brought a surprise, and necessitated something being done, called balancing, which I don't understand. The next consideration was how to turn this great increase of power to advantage. This involved putting the largest pulleys that could be got on the countershaft. To further gear down, 30 in. artillery driving wheels were substituted, with a stronger axle and stronger springs and more powerful brakes. The full power is not used on the level road, only on hills. The car carries five gallons of petrol or paraffin, as it runs equally well with either, but the smell of the latter is not agreeable. The best paraffins, "water white" or "white rose," are nearly as dear as petrol, and even they are not odourless. The car will run over forty miles on one gallon. There are no extra water tanks that I am aware of. The water is so effectually cooled that, I repeat, the car can run two days (100 miles a day) without calling for water or fuel.

The vehicle was run some time after the improvements were made with one belt, but since then some other little improvements have been added, and the other belt brought into use again. The engine is started from the seat, seldom from the back. There is one little drawback—the car has to be handled with more care than formerly, owing to the machinery generally being of too light a construction to permit of any injudicious use of the extra power, but it is a delightful little car in its owner's hands. During my holidays I rode some scores of miles in the car. On one occasion we were away three days. The first day was fine. The next was about as foul "as they make 'em," it rained unceasingly, but we went through it all, "splashing, dashing like a fish." Our outer garments defied the rain and the car defied the roads, which enabled us to enjoy ourselves under the worst conditions of weather. I still believe that the old Benz cars have got plenty of grit in them, but——.—Yours truly,

W. H. W.

IGNITION AND OTHER QUERIES.

To the Editor of *The Motor-Car Journal.*

Sir, Would you kindly tell me in your *Journal* why it is that motor-cycle makers keep so persistently to high tension ignition instead of using the magneto? If a wire becomes disconnected, is the magneto machine seriously injured owing to its working without the electric current flowing? Would any danger of violent electric shock, or fire, owing to the burning of the magneto generator, arise in such a case?

I noticed that the magneto igniters shown at the Crystal Palace would give a spark even when turned quite slowly; are magneto-ignited engines really any harder to start than those fitted with high-tension ignition?

Do pupils learning to drive at polytechnics have to have licences to drive?—Yours truly,

Cecil Jackson.

[The reason that cycle makers usually fit the high tension ignition in preference to magneto is, that it is much cheaper and more simple to fit. With reference to a wire becoming disconnected, nothing is likely to be seriously injured, nor would there be any possibility of getting a severe shock. The up-to-date magneto machines give great satisfaction with regard to starting easily, these being made to give a spark at a very low speed, making them quite as satisfactory as the high tension. Students learning to drive at the Polytechnics all have licences, although steps are being taken to try and do without this during their course of instruction.]

CHARGING ACCUMULATORS.

To the Editor of *The Motor-Car Journal.*

Sir,—As owner of two large cars and one motor-tricycle I have for several years had more than an ordinary experience with respect to accumulator charging for electrical ignition. In all I have fourteen accumulators, which I keep charged by means of my Boron cells, four in number. I obtained these through the advice of a friend of mine who had discarded the various dry cells as useless and was about to adopt accumulators. I had previously tried two makes of primary cells which had been much advertised but which only gave me incomplete results. Since employing this as a means of electric power I have never had any trouble with my accumulators, and I would most emphatically advise any owner of a car or tricycle to invest in one of these sets. I have no interest in the Boron Company save that of a satisfied user of their cells.—Yours truly,

Eustace Morgan, M.D.

THE MOTOR-CAR ACT.

To the Editor of *The Motor-Car Journal.*

Sir,—Will you allow us to call attention to what appears to us to be an injustice to dealers and would-be purchasers of motors? We had examined and repaired a motor-tricycle we had to sell, and a probable customer came into our place (at Birmingham) on Saturday, February 20th, just before six o'clock. Seeing the machine, he asked us to let him try it. We did so, and at 6.15 p.m., whilst he was relighting the lamp, an officer asked him if he had a licence. He replied, stating the circumstances under which he had got the machine, but he was summoned and fined, last Thursday, £1, and 9s. costs, for not having a licence. Now, we had paid £3 for a dealer's licence, and we have also a driver's licence, and it seems hard that we cannot let a probable purchaser try a machine unless he has got a licence first. Besides, it was impossible for him to get one first, as it was too late.—Yours truly,

J. Edmonds and Sons.

STEAM V PETROL.

To the Editor of *The Motor-Car Journal.*

Sir,—I notice in your last issue a letter from "Steamer." I am entirely in agreement with him *re* the steam car fitted with paraffin burner compared with the petrol, but I do not agree with him *re* a wheel valve to use as a starting valve, in place of the usual starting lever supplied on most steam cars. Nothing could be simpler, it being applied quicker. I have run this kind of car for two years, and can always start slowly, say at half or one mile per hour, if necessary; in fact, a cautious driver will do this. If the hand is applied simply to the lever it is impossible to start slowly, but with the hand resting on the car I adjust the lever by the thumb and first finger with ease. I have known

Digitized by Google

cars fitted with return water system, but then the steam is passed through the condenser. "Steamer" states he exhausts direct into the water tank; it would be interesting to know how long he can run in this way. I should consider the tank, in fact the whole car, gets very warm, and this I object to very much, and have fitted an automatic air arrangement to cool the seating.

There are many reasons why the steam car is going out of fashion with the public, viz., they were too lightly built, especially the wheels, the spokes of which were only bicycle gauge. I had mine taken out and replaced with No. 7 gauge, as I could not go a 30 mile journey without some out on my return. This has stopped a nuisance; in fact, I go over any roads without thinking of such a thing as a broken spoke. I have also fitted steam, air, and water pumps, superheater, water-lift, force draught, cut petrol supply down from seat, enlarged fuel and water tanks, also the water pipes, Klinger gauge, improved lubrication. I altered the hand pumps to work from seat, also the blow-off cock, which both entailed taking up footboard and putting your hands among a bed of hot pipes. The blow-off arrangement is most important, and is used every time the car is used, five out of six boilers have been scorched through this not being done. These are details only, but they make the car what it should be; there is no worry with a vehicle fitted up in this way, and I contend it is only this that has made the steam car go out (so to speak) of fashion. A practical man can make this kind of vehicle preferable to any petrol car at the price.—Yours truly,

VAPEUR.

THE MEASUREMENT OF GRADES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Referring to your article on "The Measurement of Grades," I think you will find that old locomotive practice consisted of taking the rise, dividing by the *actual length* of the slope, and multiplying by 100 to get the percentage grade, or in other words by putting $sine \times 100$, instead of $tan \times 100$, as you do. I believe the present practice still remains as I have mentioned. Of course, with locomotive gradients there is little difference between one method and the other; but if motor-cars are to be taken up the side of a house, as I noticed was being done at the last show (though on the poster only), there is considerable difference. By the older method you will see that 45 deg. would be a gradient of $\frac{1 \times 100}{1 \cdot 414} = 70$ per cent. or a little over.

It all turns upon whether we are to measure the rise in terms of the road length or in terms of an imaginary horizontal base that cannot be obtained directly. The method you describe is best mathematically; but is it best conveniently? The opinion of your correspondents would be valuable. Some of them might be able to say what is done on the Swiss railways, where "one in one," as on Mont Pilatus, is not uncommon.—Yours truly,

WILFRID J. LINEHAM.

THE COMING OF THE TWO-SEATED CAR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—The Automobile Club's Show at the Agricultural Hall is now close upon us, and there will doubtless be many who will visit this show to order their two-seated cars. It is now perfectly plain that there is an extremely good market for the two-seated car of any price from £150 to £190; but the question is, Which type of two-seated car is going to last?

In the writer's opinion, all the little single-cylinder cars are underpowered *at times*. Given a fine day and perfect roads, it will indeed be a poor car which cannot trot along at twenty miles an hour with two or even three people up. This is one side of the question, and the other is this—pouring rain, roads fearfully heavy, the little car doing its best on the slow speed.

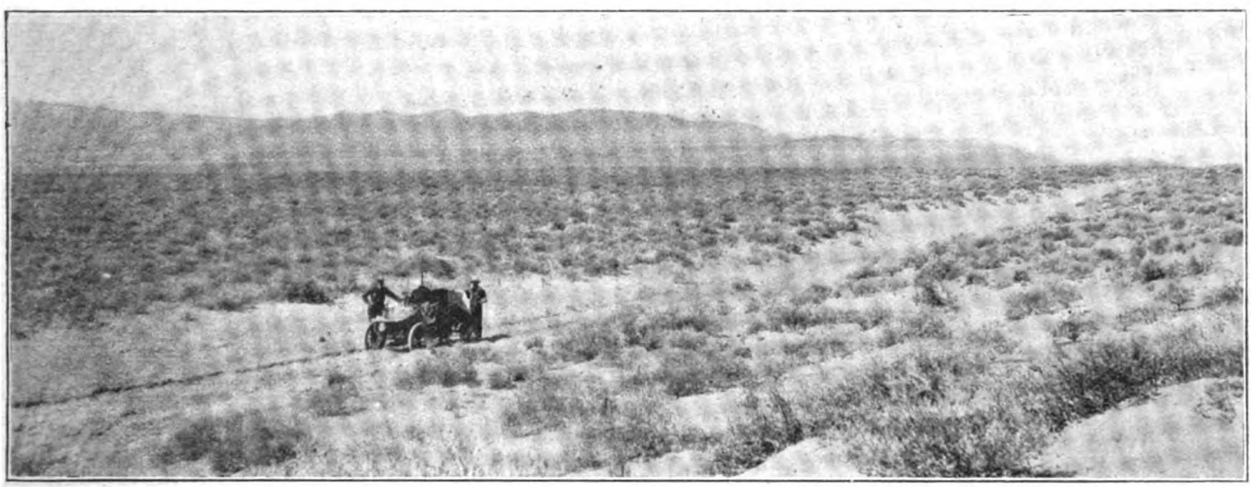
Now, the price that people are paying for little cars is about £175, *e.g.*, Wolseley, Belsize, Horbick, Siddeley, Baby Peugeot, Little Star, and others, and it is reasonable to suppose that a purchaser will go to another £10 or so to secure a little car, just exactly as the above-mentioned, only with a two-cylinder engine instead of the single-cylinder. Now a car of this type is, without a shadow of doubt, bound to be a success. It is cheap, it will easily carry three when required, as there is ample power, and there is the beautiful smooth running of the two-cylinder engine compared to the kicking of the single cylinder.—Yours truly,

C. A. R.

CHANGING SPEEDS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I should be greatly obliged if some of the readers of the *Journal* would give me their advice as to changing speeds, or rather as to the manipulation of the clutch when changing gear. What I am particularly anxious to know is whether it is better to let the clutch in as quickly or as slowly as possible. One friend has recommended the former while another is equally in favour of letting the clutch in slowly, and between the two I am in a quandary.—Yours truly,



F. J. R.

PROPOSED LAMP TEST.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—It would be of very great interest to a vast number of your readers if the question as to which lamps are most suitable for motor-cars could be clearly demonstrated by a series of reliability trial runs and competitions. Looking back on some of the most serious accidents which have shocked people, it was too often the case that the powerful headlights have failed in the task they are intended for. Hardly a day passes now but one reads of motorists being summoned and heavily fined because their tail lights have not been burning, though they might have been lighted over and over again. I think this is a matter of great urgency, to which the attention of the A.C.G.B.I. should be drawn, as the most suitable body to include in their programme of this year's trial runs also a reliability competition for motor-car lamps, to be used as headlights, sidelights, or tail lights. Perhaps motor-car owners who might be interested in such trials will give their views of the practicability of such a competition.—Yours truly,

E. BAEDEKER.

Motoring Across a Nevada Desert.

CLEAN VALVES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In answer to query of "W. A. W." in your issue of March 12th, I think he will find that the reason of one cylinder fouling its valves with soot is because t is cylinder gets more lubrication than the other. This can be remedied by cleaning out the small pipes which conduct the lubricating oil to the pistons and crank chambers It is best to do this with a piece of flexible picture-wire.—Yours truly,

W. H. CRUNDALL.

THE FRENCH ANTI-SKIDDING COMPETITION.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Being one of the successful competitors at the anti-skidding competition held in France recently, will you kindly permit me space to make a few remarks? Although the French competition was a very exhaustive one and excellently managed throughout, I think the jury made a mistake in dividing the different apparatus into so many cate-

Digitized by Google

gories, and as a result it made their task all the more difficult. In dealing with an anti-skidding competition of this kind I maintain that one class should be ample and that all should come under the same category. I would allocate the points on the following basis :—

Skidding under sudden application of the brakes ...	150	points.
Skidding on curves	150	,,
Wear and tear of the apparatus	100	,,
Effect of Anti-Skidder on speed of car	60	,,
Ease of adaptation and of fitment	20	,,
Ease of replacement of worn out parts	10	,,
Advertisement selling price	10	,,
	500	

In dealing with these points it will be necessary to have an extended trial of 600 or 700 miles, or more if possible, in order to test the endurance of the different devices, and so far as the skidding itself is concerned I think 50 yards on both specially prepared macadamised roads and sets would be sufficient.

It would almost seem that the public have an incurable tendency to confound the Anti-Skidder with the unpuncturable tyre. This is confounding two very desirable qualities for a tyre, but they should be treated independently of each other. Therefore I hold that in the French competition they fell into the error of confounding these two points, and in order to deal with all the various forms of anti-skidders they were obliged to classify them into four categories, whereas had they eliminated the three and treated with the Anti-Skidder pure and simple, then the public would have known the best device on the market, but the fact of taking the tyres into consideration makes the question of merit still an open one.

I pen this with a view to bring the point under the notice of the Automobile Club of Great Britain and Ireland, so that they can deal with it in their forthcoming anti-skidding competition.—Yours truly,

W. R. McTaggart.

DRIVERS.

To the Editor of *The Motor-Car Journal*.

Sir,—I would like to congratulate "Mechanic" on his practical suggestion for a way out of the difficulty, and to suggest that the test follow somewhat on the lines of that instituted by the Board of Trade for marine engineers. As a preliminary qualification the test should require the production of the candidate's indentures, or a proof that he has worked for at least three years with some engineering firm. If this were carried out, and the test made really searching, I feel sure that thousands of good men would soon secure their "First," "Second" or "Third-class" motor-engineer's certificate. If the certificate were kept up to a good standard, very few cases like the one described by "Chirurgeon" would occur.—Yours truly,

Ad Sum.

To the Editor of *The Motor-Car Journal*.

Sir,—The average mechanic and driver is now displaced by the one with three months' or perhaps six months' experience. It is practically no use for a man who has had three or four years' experience, and who has a present situation in the country, to try and obtain a new berth in town. He must leave his present position and go to town, and wait, perhaps, two or three months, or even more, before he obtains one. While there and out of work he sees the new and, may I say, the modern driver (with his long experience of around the park) obtain a situation for the enormous weekly wage of 25s. If a man asks £2 10s. to £3 to attend to a 16 or even 24 to 30 horse-power car he is looked upon as a lunatic. Taking, for instance, a car worth £800 to £1,000; does a gentleman want a man who runs his engine hot, takes off a wing or two, or when the engine is missing pull out a book on "how to motor," or would he prefer to have a mechanic who avoids all such calamities and keeps his valuable plaything in proper trim? If so, then the only thing is to judge between the two specimens of mechanic and driver, and see in the end which costs him the most.—Yours truly,

B. W.

To the Editor of *The Motor-Car Journal*.

Sir,—In the *Journal* you remark that the correspondence on drivers has called forth the denunciation of the certified driver. Are the mechanics justified in their remarks? They would have owners believe that it is dangerous for anyone but a mechanic to drive their car. A man who has been thoroughly taught the working and management of a car, can do running repairs, and show a responsible certificate, should at least be allowed to compete. Thorough mechanics of several years' standing, as nearly all of them claim to be, should not be out of work for several months, as there is a demand for such men at the motor works. If they are not thorough mechanics then it is dangerous for them to tamper with valuable cars, as your correspondent "Chirurgeon" can testify. All owners may not feel justified in paying mechanics' wages all the year round, especially if they are near a competent repairer, and a car carefully used should run a long time without requiring that gentleman's attention.—Yours truly,

Certified.

Accumulator Charging Sets.—Replying to Messrs. F. S. Filby and Co., the makers of the charging sets illustrated in the *Journal* for the 5th inst. are Messrs. Everett, Edgcumbe and Co., 151 and 152, Great Saffron Hill, London, E.C.

NOTES ON AUTOMOBILES.*

By B. Hopps.

Automobilism has now reached a stage when it may justly claim the attention of any engineering body. The motor-car was primarily designed as a pleasure vehicle, but it is steadily coming to the front as a means for conveying goods, etc., and may in this connection become of considerable importance, as, for example, in postal and military transport, and also in forming feeders to our main railways, thus cheapening the conveyance of country produce to the towns.

By far the greater number of motor-cars running to-day are driven by oil engines using either petrol or alcohol as fuel. There are several factors which go to make the petrol engine the most satisfactory motor for driving automobiles. In the first place it is a very compact, and is practically self-contained, requiring no equivalent to the boiler or the heavy storage battery. Fuel and cooling water can conveniently be carried, to enable the motor to run for long distances without stopping for replenishment. The petrol motor has the further advantage of being extremely light for the power developed, the weight of an average engine being in the neighbourhood of 18 lb. per h.p. Satisfactory engines have been built weighing as low as 5½ lb. per h.p. Other points favourable to the petrol engine are the fact that it requires but little attention when running, the lubrication being entirely automatic. It can be instantly started at any time, and is comparatively cheap to run, costing on an average for petrol and lubricating oil for a 16-h.p. car carrying four passengers, about 0·75 of a penny per mile, equivalent to ·58 of a penny per ton mile.

The most serious disadvantage of the petrol engine is its inability to exert an increased torque at low speeds. For this reason it is necessary to introduce a change speed gear, to enable the car to climb steep grades. A great deal of attention is at present being paid to improve the flexibility of the petrol engine, as, for example, by increasing the number of cylinders, and therefore the impulses per revolution. To this end several of the leading makers are introducing six, and even eight-cylinder engines in their new models. Whether the advantage gained by this multiplicity of cylinders will out-balance the additional complication remains to be seen. A second disadvantage of the petrol engine is that it requires starting either by hand or by some auxiliary power. It is a fact, however, that some four-cylinder engines will restart by themselves, providing they have not been standing too long; this is owing to one out of the four cylinders always coming to rest with the piston on the firing stroke; if this cylinder is then fired, the engine will start away without any further trouble.

Considering now the component parts that go to make up a modern petrol car: We have in the first place the engine. The general type in use to-day has vertical cylinders working on the Otto cycle, *i.e.*, an impulse every other revolution. In all but the smallest-sized engines two or more cylinders are used, thus providing a more regular turning moment, and less vibration. General practice shows the following relation between size of engine and number of cylinders used :—

Up to 8-h.p.	Single cylinder.
From 8 to 12-h.p.	Double cylinder.
From 12-h.p. upwards	Four cylinder.

From the exhibits at the recent shows, it appears that three-cylinder engines are receiving considerable attention from the leading makers. They are undoubtedly cheaper than the four-cylinder type, take up less space, and are probably quite as flexible in their running qualities.

Cylinders, pistons, and piston rings are usually made from cast iron; cylinder, combustion head, and valve seats being cast in one. Steel tubes have been tried for cylinders with varying success. Crank shafts and connecting rods are of best steel forgings, though nickel-steel is largely used for this class of work, bearing liners are of phosphor bronze, and crank-chamber cases of aluminium alloy. Valves are of the mushroom type, and are generally of nickel-steel, which metal seems better able to resist the burning action of the hot gases. With a few exceptions, two valves only are used per cylinder, *i.e.*, inlet valve and exhaust valve. The exhaust valve is held to its seating by a spring, against which it is lifted by a cam keyed to a shaft, running at half the speed of the engine main shaft and driven therefrom by the gear wheels, generally enclosed in the crank-chamber case. The inlet valve is either automatically operated by the suction of the piston, or—which is a more modern practice—is mechanically operated in the same manner as the exhaust valve, and from the same shaft. There has been considerable controversy as to which is the most effective method, but, judging from results, engines with mechanically-operated inlet valves are quieter in running and have a wider speed range than those with automatic valves; the latter, however, are simpler and cheaper, and more often used on smaller engines.

The automatic inlet valve is made as light as possible, and is held to its seating by a comparatively weak spring, the tension of which is overcome by the suction of the piston on its downward stroke drawing in the explosive gases through the valve opening. At the bottom of the suction stroke the valve should immediately close, and allow the explosive charge to be compressed by the upward movement of the piston. In actual practice, when the exhaust valve closes after the exhaust stroke, the combustion space is filled with burnt gases, which are slightly above atmospheric pressure; the piston has therefore to travel some distance on its downward stroke to allow these gases to expand before sufficient suction is obtained to open the inlet valve. It is therefore late in opening, which

* Abstract of a paper read before the Rugby Engineering Society.

Digitized by Google

is detrimental to obtaining the full power of the motor. Again, at the end of the suction stroke the valve tends to remain open longer than is necessary, owing partly to its own inertia and that of the inrushing gas—a portion of the cylinder charge is therefore blown back before the valve has time to close. This has a greater tendency to occur with large valves. To overcome the valve inertia and to reduce the lift, one firm uses three small valves arranged in a triangle, giving the same area as a large single valve. It is obvious, from what has been said, that with automatic valves a great deal depends on the strength of the inlet valve spring, and to obtain the best results this should be varied with the speed of the motor. It is interesting to note that with an engine running at 1,000 revolutions per minute, the inlet valve must open and close in three-hundredths of a second. Under these conditions the inertia of the valves must play an important part in the operation of the engine. The mechanically-operated valve is held to its seat by a strong spring, against the tension of which the suction of the piston has no effect. The opening and closing is definitely determined by the shape and position of the cam by which it is lifted. The disadvantages inherent to the automatic valve are, therefore, to a great extent overcome.

Nearly all motors with the exception of the smaller sizes are governed. The method usually adopted is to vary the amount of explosive mixture delivered to the cylinder. This is accomplished either by introducing a throttle valve in the inlet pipe, or by varying the amount of lift on the inlet valve itself; in either case a centrifugal governor is used to obtain the necessary motion. This method of governing is theoretically bad, as it reduces the compression, and, therefore, the economy of the motor. In automobile engines, however, economy plays but a secondary part where simplicity of construction is of primary importance. Another method is obtained by varying the lift of the exhaust valve, thus retaining more or less of the exhaust gases in the cylinder, which prevents a fresh charge from entering until they are expanded below atmospheric pressure Whichever method is used, an arrangement is generally provided in the shape of a foot or hand lever, which enables the governor to be cut out and rendered inactive; the speed of the engine may then be accelerated beyond the normal. Such a device is known as an accelerator.

At the speed at which petrol engines are run, the time allowed for the explosion stroke is about three-hundredths of a second. Quite a considerable part of this short space of time is required for the explosive gas to actually ignite, from the instant the firing spark occurs. To obtain the full expansion value of the gas, it is found necessary to advance the period of ignition, that is to say, to cause the firing spark to occur at some time before the piston reaches the end of its upward compression stroke. The amount of advance to be given to the spark will depend on the speed of the engine. At starting, the spark is arranged to occur just as the piston passes the dead centre on its downward explosion stroke. If attempts were made to start the motor with the spark advanced, the slow piston speed at starting would give time for the charge to ignite before the piston reached the top of the compression stroke, the piston would therefore kick back, and probably cause some personal damage in the shape of a broken arm or wrist.

The temperature of the burning gases inside the cylinder of a petrol engine is in the neighbourhood of 2,000 deg. F. To keep the cylinder walls at a temperature below the flashing point of the lubricating oil it is usual, with all but the smallest motors, to water-jacket them. With small motors up to 3-h.p. placed in an exposed position—as, for example, on a motor-bicycle—the rush of air when the machine is in motion, against radiating ribs cast on the outside of the cylinder, is sufficient to keep it cool, except when such a motor has to climb a long steep grade at a necessarily slow speed. Then the cylinder may over-heat—this is followed by a loss of power from the motor, probably due to the inrushing gases striking the hot cylinder walls, and immediately expanding, thus preventing any further gas from being admitted. The result is a lower mean pressure on the explosion stroke, and therefore less power. It is also obvious that too high a cylinder temperature may burn up the lubricating oil, and cause the piston to seize.

The exhaust gases on leaving the cylinder are driven into the atmosphere at a comparatively high pressure, and unless some silencing device is used, the rapid expansion produces a noise that can only be compared to that of a Maxim gun. To deaden this sound it is necessary to slowly expand the gases, and eventually exhaust them at a low constant pressure, but this must be done without creating an unnecessary back pressure, which would otherwise reduce the power of the engine.

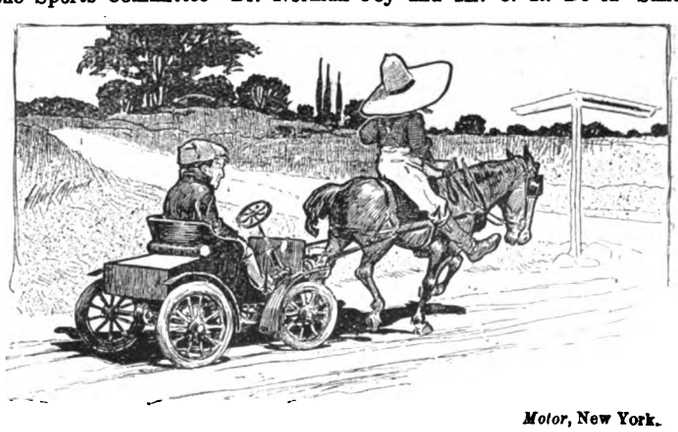
Petrol is the name given to spirit obtained by distilling petroleum. Its specific gravity ranges from ·68 to ·72; its boiling point is about 38 deg C. It is extremely volatile at all ordinary atmospheric temperatures, and when mixed with air in the proportion of one volume of liquid petrol to 10,000 volumes of air, forms a highly-explosive gas, which, when compressed and ignited, expands from three to four times in volume.

Passing from the engine and its accessories, the next important feature is the transmission gear. The engine is connected to the gear-box through a clutch by means of which the driving power may be gradually applied, as in starting, or may be temporarily disconnected to enable the gear wheels to be moved in and out of mesh when changing speeds. To further reduce shocks to the mechanism, some makers transmit the power between clutch and gear box through a stiff spiral spring, which is very effective in taking up any sudden shocks. The general type of clutch is the cone variety, in which the engine flywheel forms one portion, and a leather-faced cone forms the driven member. The rim of the engine flywheel is overhung, and the inner face is turned conically. The engine shaft is extended beyond the flywheel boss, in order to carry the main portion of the clutch; the two portions thus mounted together on the same shaft cannot get out of line A strong spring is arranged to press the faces of the cones together, but in such a manner as to cause no end thrust on the engine or gear box bearings. The clutch is, therefore, nominally in engagement, but can be released by means of a foot pedal, which compresses the spring, and draws the cones apart This type of clutch may give trouble by slipping caused by water, or an excess of oil getting on the face of the leather. An adjustment is always provided whereby the compression of the spring may be increased. There are other forms of clutches, a novel one being a magnetic variety which has the advantage of being very gradual in its action, and easily controlled, and in which all degrees of slip can be obtained without causing excessive wear. It requires, however, a battery or small dynamo to excite the magnetising coils, which can be controlled to a nicety by a small rheostat.

The gear box, after the engine, is the most important piece of mechanism in a petrol car. Innumerable schemes have been devised for obtaining a variable speed ratio between engine and road wheels, but so far the Panhard type gear seems to be the only really successful system, and is generally adopted. It consists of two sets of gear wheels of different diameters. One set is rigidly fixed to the shaft they drive, whereas the other set, driven from the engine, is movable by means of a lever under the driver's control, and allows each gear wheel to be slid into mesh sideways with a corresponding gear wheel in the fixed set, thus providing various speed ratios. The gears are enclosed in an aluminium oil-tight case, which is filled with grease and oil.

The two accepted methods of transmitting the power from gear box to road wheels are either by a live back axle or side chains with a fixed axle, the former method for cars up to about 25-h.p. and the latter for larger-powered cars. It is necessary with the live axle to divide it at some point to accommodate the differential gear, and this undoubtedly constitutes a weak point, and limits its use for high-powered heavy cars, although it has the advantage of requiring less attention, and being quieter in running than chains.

The gear box is connected to the live axle by means of a flexible shaft and a bevel gear, inside of which is arranged the differential gear, which compensates for unequal turning of the road wheel when rounding corners. The flexible shaft is arranged to telescope, in order to allow for the alteration of centres, as the car frame rides on the springs. With the fixed axle, the bevel and differential gears are located in the gear box, from which a shaft projects each side, on the ends of which are keyed sprockets, which drive through chains to chain wheels fixed to the road wheel hubs. In either method of drive radius rods are fitted from the back axle to a joint on the car frame, their function being to relieve the back springs of any driving strains, and, in the case of the fixed axle, to afford a means of tightening the driving chains.



CLUBS AND ASSOCIATIONS.

EASTERN COUNTIES.

The Eastern Counties' Automobile Club has issued a neat pamphlet containing a list of members, the rules of the club, a directory of local petrol dealers, and other useful information. An interesting programme of club runs has been arranged, commencing on May 28th with a trip to Felixstowe. The meet will take place at the Great White Horse Hotel, Ipswich, at 3 p.m., and tea will be taken at the Felix Hotel, Felixstowe, at 4.30 p.m.

BERKSHIRE.

On Saturday the general meeting of the Berkshire Automobile Club was held at the Great Western Hotel, Reading, Sir Gilbert East, Bart., in the chair. On the motion of the chairman, Mr. Carew Gibson was elected to the committee, and the proposed rules were unanimously adopted. Suggestions were then invited for the membership of the Sports Committee and other matters connected with the arrangement of meets, &c. The names of two gentlemen were proposed as members of the Sports Committee—Dr. Norman Joy and Mr. C. R. De la Salle.

Motor, New York.

Digitized by Google

The chairman had already given an invitation for the first of the sports fixtures, to be held at Hall Place on the Saturday in Whitsun week (May 28th) and to take the form of a "gymkhana." It was further resolved that, beginning with this fixture on May 28th, there should be "meets" or other fixtures at different places on the last Saturday and second Wednesday in each month, except August, up to and including September. The club, it was incidentally mentioned, has already seventy-one elected members.

WOLVERHAMPTON.

The sub-committee appointed by the Wolverhampton Automobile Club for the purpose of finding quarters for that organisation has gone fully into the matter, and the committee have agreed to secure three rooms in the new London Buildings, Lichfield Street, Wolverhampton, for a term of three years, from the 25th of March, which will be converted to the purposes of the club. The annual subscription, it is suggested, will be two guineas. There is no doubt that the accommodation provided will do much to promote the prosperity of the club. At the annual general meeting, the following officers and members of the committee were appointed:—*President:* Mr. J. Osmond Evans; *Vice-presidents:* Alderman Levi Johnson (Mayor), Sir Alfred Hickman, Bart., M.P., Mr. H. Norman, M.P., Captain Burnett (Chief Constable, Wolverhampton), Mr. J. H. Cooksey (Town Clerk, Bridgnorth), Mr. E. Lisle, and Mr. W. Owen; *Committee:* Messrs. F. C. Bishop, T. Cureton, G. Evans, W. H. Evans, H. W. Jenks, T. Lisle, T. Mills, and T. Young; *Hon. Treasurer:* Mr. A. E. Jenks, Southbank, Compton, Wolverhampton; *Hon. Secretary:* Mr. S. R. Rhodes, Lichfield Street, Wolverhampton. It was resolved for the present not to affiliate with the A.C.G.B.I., but to devote the amount which would be necessary for that purpose towards furthering the interests of automobilism locally.

MIDLAND.

In the annual report of the Midland Automobile Club, the membership is recorded as having increased to 116. Reference is made to the various competitions and runs held during the year, and the hope expressed that members of the club will make more use than hitherto of the club headquarters at the Grand Hotel, Birmingham.

NOTTINGHAM.

The Nottinghamshire Automobile Club had a run to Melton Mowbray on Saturday, and a hill climbing competition at Abb Kettleby Hill, some three miles distant. Upwards of forty cars took part in the run, and a good many in the competition, which was over a measured mile, the first six being as follows:—Mr. W. Foster, 24-h.p. Georges Richard, two passengers, 1; Mr. H. Belcher, 25-h.p. Humber, two passengers, 2; Mr. W. Bartleet, 18-h.p. six-cylinder Napier, four passengers, 3; Mr. R. Sutton Clifford, jun., 18-h.p. Mercedes, three passengers, 4; Mr. W. H. Arnott, 14-h.p. Gladiator, three passengers, 5; Mr. E. W. Wells, 14-h.p. Daimler, two passengers, 6. The annual dinner of the club was held the previous evening, Mr. C. E. Lucas in the chair. A very enjoyable evening was spent.

SOUTH LINCOLNSHIRE.

A committee meeting of the South Lincolnshire Motor Club was held at the headquarters, the Red Lion Hotel, Boston, on Monday, the chief business being to arrange meets for the coming season. Dr. Miller occupied the chair, and there was a full attendance of the Committee present. The following meets were arranged for:—

April 4th (Monday), Spalding.
April 28th (Thursday), Boston.
May 7th (Saturday), Holbeach.
May 19th (Thursday), Woodhall Spa.
June 2nd (Thursday), Spilsby.
June 16th (Thursday), Wrangle.
June 23rd (Thursday) Horncastle.

Later meets will be arranged at a subsequent meeting of the committee.

A DRUNKEN DRIVER SENT TO PRISON.

H. W. Sewell, a motor-car driver, after finishing his work with his employer went for a ride on his own account one day last week. He came into collision with a cab, injuring several persons. Upon the police stopping him it was discovered he was drunk, and at the Marylebone Police Court he has been sentenced to a month's imprisonment.

MOTOR-CAR REPAIRS.

At the Bow County Court, Wm. George Conningham, a motor expert, brought an action to recover £8 4s. 7d. from Dr. Noble, of Church House, Hoe-street, Walthamstow. The claim was made in respect of repairs which had been done to the doctor's motor-car from time to time. The doctor admitted most of the items, but took exception to charges of three guineas and £1 3s. respectively for repairs, and a small sum for oil, which he said had been charged for at too high a rate. The judge said he thought some reduction should be made in the charges for repairing the car after it broke down, for it was evident that a great risk was taken in running it in such a condition. He should also reduce the charges for oil, and give a verdict, with costs, for £6 2s. 7d. or two guineas less than the amount claimed.

CASE DISMISSED.

On Monday, at the Steyning Petty Sessions, John T. Hampton, of Haywards Heath, denied driving a motor-car at a greater speed than 20 miles an hour at Henfield on the afternoon of February 28th last. P.C. Thomson said that a measured half-mile along the Woodmancote road was covered in 1min. 13secs., which was about 24½ miles an hour.

Mr. E. E. Humphrys, instructed by Messrs. J. E. Dell and Loader, of Brighton, defended, and elicited from witness that when he set the watch going he did not look to see if it started directly. He questioned witness closely as to the system of timing, pointing out, during the course of it, that an ordinary stop-watch and not a chronograph was used, and also questioning the measurement of the distance. P.C Collyer, who also gave evidence, had a watch in his possession which Mr. Humphrys intimated was the proper kind to use. For the defence, Mr. Humphrys stated that during the five years his client had been driving he had never had an accident and never been summoned, nor even cautioned. A watch of the nature used by the witness Thomson was absolutely unreliable. Mr. Humphrys further contended that, as his client had slowed up to almost a walking pace on negotiating the corner, around the other side of which was the constable Collyer giving the signal, he could not have been going at his top speed (18 miles an hour) on passing that official. Reverting again to the stop-watch question, Mr. Humphrys declared that Major Lang, the East Sussex Chief Constable, used the electric signal, because he had come to the conclusion that stop-watches were unreliable, while, in a case in Surrey, a summons had been dismissed because it was thought that the stop-watch in question might have "hung fire," such as the one used by P.C. Thomson was likely to do. Superintendent Hooker having questioned defendant, Ernest Adams, principal assistant to Mr. Booth, of Preston-street, Brighton, gave expert evidence on stop-watches. In the case of a watch similar to that possessed by P.C. Thomson, he said, should it happen that the balance wheel—which was stopped in that kind of watch—was in a resting position, it would require other than the power of the main spring and the hair spring to make it go, and they could not absolutely rely on their always acting properly. He intimated that under this condition a slight vibration was required before a watch of this class would go even directly after being wound up. Eventually the magistrates decided, under the circumstances, to dismiss the case.

MOTORIST v. MOTORIST.

At the Basingstoke County Court, Earl Russell has brought an action for damages sustained by his motor-car in a collision with one belonging to the War Office at Basingstoke, on September 26th last. After a lengthy hearing, his Honour Judge Gye delivered judgment for the defendant with costs. He had, he said, had considerable doubts as to what that judgment should be till he was half-way through the case. At the outset he would like to say that Lord Russell had disproved the truth of the saying about the man who was his own lawyer. He had never heard a layman conduct a case with so much skill, patience, and good temper as Lord Russell had done. The facts were that up a somewhat narrow street Lord Russell drove his motor-car at a speed of nine or ten miles an hour, that the Market Place was full of stalls, and being therefore unable to cross that he had to turn the corner into the London Road. Just as he was doing that the military motor-car was approaching in the opposite direction at a rate which the driver said was about four or five miles an hour. The evidence given on behalf of Lord Russell was that he had turned the corner and drawn the motor in fairly close to the kerb, short of the lamp-post. Lord Russell said the car had stopped dead, and almost immediately the collision occurred. It was admitted that there were waggons on the other side of the street, and that the military car, in order to pass these, had to go towards the wrong side of the road, which it was entitled to do. Having passed the waggons, the military driver was just steering his car back to its proper side, when he saw the plaintiff's car quite close. Immediately he saw that he shut off the power and put the brakes on. This was only done at a point of time which allowed the military car to run a yard and a half before the collision occurred. That, Lord Russell said, was evidence of negligence on the part of the defendant, but the answer might be that Lord Russell's car was going a great deal faster, and covered several yards while the defendant's car ran a yard and a half. In conclusion his Honour said he found that the accident was caused by Lord Russell turning the corner at too fast a pace, and that there was no evidence of negligence on the part of the defendant. The result of that was judgment for the defendant, with costs.

A motor service will be inaugurated from Llanstephan to Carmarthen on the 2nd prox.

With reference to the non-stop run of the 6-h.p. Wolseley from London to Edinburgh, the Northern Counties Motor Garages, Limited, write that they have a large garage at 27, Pilgrim Street, Newcastle-on-Tyne. A resident engineer is always in attendance, and the garage can be opened any hour of the night by simply pressing the electric bell fixed on the left hand side of the door

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, MARCH 26, 1904. [No. 264.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

AS was recorded in a recent issue, His Majesty King Edward has lately added a 18-24-h.p. Mercedes to his fleet of motor-cars, and on Tuesday of last week made his first run on the vehicle, of which we give an illustration on page 66. The car, which is the second of the 1904 18-24-h.p. models turned out from the Cannstatt works, was ordered last year through Messrs. Arnold Spitz, & Co., of Vienna. The illustration shows Herr Eidlitz, of that firm, at the wheel. The vehicle is superbly finished and equipped, and forms a notable addition to His Majesty's numerous stud of cars, which now, we believe, includes examples of English, French and German construction.

◆ ◆ ◆

Activity at Winchester.

THE Local Government Board having appointed one of its inspectors to hold an inquiry at the Guildhall, Winchester, on Thursday, the 24th inst., with respect to the City Council's application to have the ten miles limit put in force on all the roads in the Borough, the Club Committee of the A.C.G.B.I. appointed Earl Russell and the Hon. J. Scott Montagu, M.P., as a sub-committee, to watch over the interests of the Club at the inquiry and to instruct counsel on behalf of the Club. On Saturday last Earl Russell and the Administrative Secretary visited Winchester and instructed Mr. Warner, solicitor, and through him, Mr. Ricketts, to appear at the inquiry on behalf of the Club. The Hampshire Motor Union will also be represented by Mr. Ricketts in opposition to the proposal, and amongst the witnesses to be examined are Earl Russell and the Admistrative Secretary, on behalf of the A.C.G.B.I.; the Hon. John Scott Montagu, on behalf of the Hampshire Motor Union; and a number of local motorists, hotel proprietors and leading ratepayers who are opposed to the proposed speed limit being put into force.

◆ ◆ ◆

The Exhibition.

THE reputation of Cordingley's Motor Car Exhibition as the place for actual business as well as for gaining publicity has again been demonstrated this week, and the attendance of buyers and really interested persons as distinct from mere sight-seers has been extremely satisfactory to exhibitors, who seem to have been well pleased with the business done and the enquiries they have had. It now remains for these introductions to be keenly followed up by the firms concerned.

◆ ◆ ◆

Some popular Features.

AT 10 p.m. to-day (Saturday) the Exhibition will close its doors, and the event of the year will be over. Those who have not already visited the Hall have therefore little time to lose, and will no doubt take the last chance that remains to see a show that has been welcomed by press and public as attractive beyond the ordinary range of exhibitions. To this popularity the Air-Ship Section has contributed its quota, while the presence of a band and the general pleasing character of the display made by exhibitors must be regarded as other factors in the success.

◆ ◆ ◆

Up in the Air.

IN the Aero Club's exhibition is a model of Dr. Barton's air-ship, the central point of interest being the Beedle air-ship. In one corner Messrs. Spencer, the well-known balloonists, have a display of balloon cars, tractors, grappling irons, ropes, and other "things of the air" with which their name has been connected for three generations. Mr. Spencer is confident of the ultimate success of their airship schemes, and they are now actively engaged on another which should be ready for further experiment in the autumn. It was rather curious to hear that there is a brisk demand for balloons, several English gentlemen having lately purchased such luxuries. There is apparently something attractive in the idea of taking tea in the clouds as a minor pleasure in connection with a garden party.

◆ ◆ ◆

The Motor Union.

THE annual meeting of the Motor Union was held at the Agricultural Hall on Tuesday, Lt.-Col. Holden, the new chairman of the A.C.G.B.I., being in the chair. The report for the past year was moved by the chairman, and having been seconded by Mr. C. T. Langridge, was adopted, after some discussion. The various items on the agenda were severally considered and adopted with the exception of the clause relating to the revised rules, which was referred back to a small sub-committee to be appointed by the general committee. The findings of this will in due course be submitted to the members of the Union, in general meeting, for consideration. The proceedings terminated with a hearty vote of thanks to the chairman, and a similar vote, proposed by the chairman to Mr. Roger Wallace, K.C., the late chairman, as an appreciation of the enormous amount of labour and time he had given to the Motor Union.

◆ ◆ ◆

A Motor May Day.

DESCRIBING the parade of motor vehicles along the Thames Embankment last May Day we ventured on the suggestion that the assembly of heavy vehicles might become an annual institution, and that "Motor May Day" would be an appropriate addition to the calendar of events. The idea is about to be realised, and the first work of the newly-formed Motor Van and Users' Association will be to arrange for a Motor Van Parade that will be associated with the early springtime. This was decided upon at a meeting held at the Agricultural Hall, London, on Tuesday, when a fund was opened to meet the expenses of the Parade. These will necessarily be heavy, but the educational value of the event should prove sufficient to induce firms interested in the development of the movement to subscribe with the liberality and promptitude that has characterised other branches of the industry in the organisation of trials and the like.

Digitized by Google

The Motor Van Users' Association.

At the meeting of the Motor Van Users' Association, already referred to, some useful appointments were made. Colonel Crompton, R.E., was elected chairman, Mr. E. Shrapnell Smith, hon. treasurer, these two gentlemen, with Mr. Douglas Mackenzie, being also appointed to represent the society on the general committee of the Motor Union. Mr. W. Rees Jeffreys is the secretary. The election of Mr. Staplee Firth as solicitor was confirmed upon which fact both that gentleman and the Association are to be mutually congratulated. Mr. Firth's services in connection with the Motor Union have proved of such value to automobilism that it is gratifying to know he will continue to act as solicitor to that body, and, altogether, it would appear that the legal rights of users of heavy vehicles, as well as of motorists generally, are to be keenly guarded.

◆ ◆ ◆

Cardiff and Motor-'Buses.

The outcry raised in some of the outlying districts around Cardiff at the refusal of the Corporation to grant licences to the South Wales Transport Company to run motor-'buses from Cardiff to Llanishen and Llandaff has had its effect, and already the question has been mooted that if it would pay a private company to run motor-'buses over these routes it would also prove profitable to the Corporation. One or two members of the latter body have decided to bring the matter before the Corporation. In addition to Llandaff and Llanishen, other districts which might well be served in this way are Whitchurch and St. Mellon's.

◆ ◆ ◆

A New Record.

On Tuesday of last week Messrs. Mann and Overton subjected one of their 24-h.p. Georges Richard cars to a long distance non-stop trial. A start was made from the Automobile Club House in Piccadilly, W., and the run was *via* St. Albans, along the main road to Nottingham. Unfortunately, about thirty-eight miles from the start, the engine was brought to a stop accidentally, in changing gear when encountering a herd of cattle on the road. The stop was only momentary, and the journey was recommenced, the route after Nottingham being *via* Lincoln, Newark, and along the great North road to Hatfield and St. Albans. At this point a return was made to Nottingham, practically the same route being followed, the round trip being made four consecutive times. Altogether 1,038 miles were covered, no less than 1,001 of which consisted of an absolutely non-stop run so far as the engine was concerned, while, as for the car itself, it was only stopped once in this long journey owing to an understanding when changing drivers, this change being made at St. Albans at the end of each round. Petrol was carried into a large tank in the tonneau, whence it was run into the ordinary fixed tank. No water was taken in after the start, and at the conclusion of the trial only seven pints were found to have been used. Mr. J. T. Overton and Mr. Ross Browne shared the onus of driving, the Observers being Messrs. F. Straight and C. Stevens, appointed by the Automobile Club. This notable journey creates a new record in non-stop runs on the road. The accompanying illustration depicts the car and its passengers at the end of the trying journey. We may add that the vehicle is on view at the Exhibition at the Agricultural Hall.

◆ ◆ ◆

Rules of the Road.

Occasioned by our remarks on the speed of pedestrians in last week's issue, Colonel J. R. Magrath writes suggesting that it is not those who walk on the roads who are foolish, but rather the rules by which they are governed. He points out that whereas mounted people are required to keep to the left, the roadway pedestrians are advised to keep to the right when walking along the path; and to absent-minded persons this is a source of confusion, often resulting in accidents. We quite agree with the gallant Colonel that uniformity in this matter is as advisable as it is necessary in many others, but the point to which we wished to give importance was the indecision which characterises a good many people when attempting to cross a roadway, and the noise of a motor-car or even a horse-drawn vehicle is heard. Every driver knows the risks that are run on this account, and hence our comment of last week.

Digitized by Google

Marine Motoring.

In view of the interest taken by visitors to the Exhibition in the motor-boats on view, some importance attaches to the annual general meeting of the Marine Motor Association, which has just been held at the Golden Cross Hotel, Charing Cross, S.W. There was a fair attendance of members. Major Lindsay Lloyd was elected president, and Captain R. T. Dixon and Mr. H. G. A. Rouse vice-presidents. The membership now includes close upon 100 of the leading owners in the kingdom. A new treasurer was appointed in Mr. B. Redwood, while Mr. Linton Hope was re-elected hon. secretary. Evidently the organisation of owners of motor-boats is proceeding at a rapid rate.

◆ ◆ ◆

Alleged Police Perjury.

Cases of alleged perjury by the police have lately been too frequent to be comforting either to members of the force or to motorists who run the risk of falling victims to the over-zealousness of officialism. A case of this kind has been mentioned at the West London Court, and one heard at the Epsom Petty Sessions has just been dismissed. A constable was summoned for wilful perjury in giving evidence against a motorist. But although the evidence of the gentleman who hired and drove the car was given in corroboration of the dealer, who was apparently wrongly summoned, the magistrates, while acknowledging that mistakes had been made, dismissed the case.

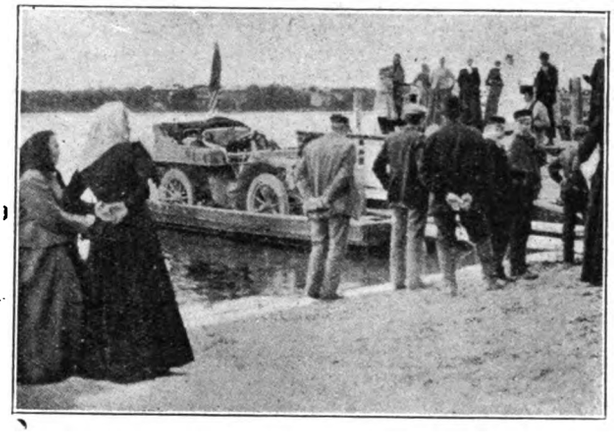
◆ ◆ ◆

Innkeepers and Motorists.

We understand that the Innkeepers' Bill which was introduced into Parliament last session is again to be brought forward, but the prospects of further legislation on the subject with which it deals are rather far removed in the present state of political parties. The provisions which it seeks to enforce are such as will commend themselves to everyone in the habit of touring or travelling on the great roads of our country. The licensed victuallers are often in a much better position than those in any other class of trade to cater for the creature comforts of people who journey by road. Especially is this noticeable in country districts and in small villages, where, as a rule, the public inn, now grandiloquently designated as an hotel, is the only place where the wayfarer, whose appetite has been whetted by a long motor-ride, can find refreshment. To restrict, therefore, the facilities of obtaining both food and drink is an unwise policy which the licensed victuallers cannot afford to pursue, in view of the unsettled state of public opinion.

◆ ◆ ◆

Colonial Automobilism.



Some idea of the progress of automobilism in the colonies comes to hand with the last issues of the New Zealand journals just received. These are devoting columns to the publication of notices on "Motors and Motoring," which not only record Colonial doings, but also comment on the advance being made by the motor-car movement throughout the world. At Auckland a motor-wagonette is now plying for hire, and amateurs there have combined in an automobile association. Great doings have taken place and a carnival was held on a recent day, in which motor-cars were prominent. At Rotorua, near the New Zealand capital, a motor-'bus syndicate has been started, and has already proved a success, so that the automobile movement at the other end of the world is as varied and healthy as it is at home.

◆ ◆ ◆

Motor 'Buses at Eastbourne.

Our reference to motor-'buses at Eastbourne last week has brought a letter from Mr. J. K. Brydges, the borough municipal engineer, who points out that "the large expenditure on account of the tyres was entailed in consequence of the wrong size and type of rubber tyres being fitted in the first instance, owing to there being no reliable data to go upon as a guide in this respect. I think all those now running motor-'buses have come to the conclusion that twin tyres on the driving wheels are a necessity, single tyres being so liable to sideslip. No doubt, the cost of tyres per car mile, 4·09d., will be largely reduced in the future, and, as a matter of fact, we have a guarantee from a firm with whom we are now doing business to maintain tyres at 2 2-5 pence per car mile, so that the cost will certainly not exceed this, and should they be purchased in the ordinary way without a guarantee the chances are that the cost will not exceed 2d. per car mile." The profit of only £67 to which we referred was the net profit after deducting £169 for interest and the redemption of the sinking fund, so that the gross profit was really £236. When the additional 'buses that are now on order for the Eastbourne service have been delivered there will be nine at work, consisting of seven single deck and two double deck cars, two of the former and one of the latter being driven by steam, generated from a paraffin burner, and the others driven by internal combustion engines.

◆ ◆ ◆

Crossing the Ferry. [*Motor, New York.*

◆ ◆ ◆

A Social Colonial Club.

The Automobile Club of Victoria has been holding several meetings, at which the question of trade or amateur has been exercising the minds of the speakers to a considerable extent. Several resolutions on the subject of members of the trade being allowed on the committee have been considered, and after much discussion it has been decided that the trade element shall be wholly eliminated from the committee. Attempts to introduce even three members of the trade were unsuccessful, and it is evident that the Australian Club has decided to get on social lines rather than those of encouraging and developing the industry.

◆ ◆ ◆

Dealers' Marks.

Very curious is the way in which the various local authorities have assigned marks to dealers. In most places a haphazard distribution of letters has been made, without any settled plan by which the traders can identify one another's vehicles. In some small places the initials of firms have been allowed as the index letters. Perhaps the most satisfactory method is that which was followed at Birmingham, where, as far as possible, the first and last letters of the firms' names have been combined as the mark. Thus L R. indicates Lanchester Company, W.Y. at once establishes the identify of the Wolseley Company's vehicles, and so on. This is really an adaptation of the suggestion we made that the names of the counties should be considered by the Local Government Board in assigning letters.

Nothing like Leather.

THE leather trades, which, a few months ago, were seriously alarmed at the advance of the motor-car, are now beginning to adapt themselves to the altered condition of things. This is the right policy, and one that coachbuilders have carried out with considerable advantage to themselves. It is true that the motor-car will, of course, affect the number of horses employed; but, on the other hand, the leather trade will find an increased outlet in travelling bags, tool kits, leather upholstery for carriage seats, etc., and the score and one other things which have to be constructed of leather. There is no reason for weeping and wailing. All that the leather trades will have to do is to study the details of automobilism, and to attempt to cater as efficiently for the motor-car as they have hitherto done for the horse.

◆ ◆ ◆

The Catalogue of the Show.

GREAT success has attended the catalogue of the Exhibition, and visitors have rightly regarded it as a comprehensive guide to the automobile industry at the present time. The catalogues at successive shows give a good idea of the progress of the industry, and are filed by many motorists as a real index to the advance of the automobile movement. The catalogue of the show, which closes to-morrow can be obtained in the Agricultural Hall by visitors, or will be sent, post free ninepence, from the permanent office of the Exhibition, 39-40, Shoe Lane, E.C. Some idea of the development of motor-car exhibitions may be gleaned from the fact that the catalogue of last year's Exhibition at the Agricultural Hall contained 184 pages that of the Crystal Palace Show this year only 164, and was sold at one shilling. That of the present exhibition at the Agricultural Hall extends to 200 pages, and is published at sixpence in order to secure the widest possible publicity for exhibiting firms.

◆ ◆ ◆

The South African Club.

FROM the Automobile Club of South Africa comes a handbook which gives a good idea of the popular favour with which automobilism is being received among the governing classes of the Colony. In addition to a report of the annual meeting and a membership roll containing sixty names there is a useful table of distances between Cape Town and various places in South Africa We welcome the growth of such organisations in the colonies and abroad, for their existence should make easy the way of motorists from other lands journeying along their roads.

◆ ◆ ◆

The Use of the Highway.

LAST week, at the Automobile Club. Mr. Morsby White read a paper on the use of the highway, and gave the following advice:—When overtaking give plenty of room. The driver of a vehicle is not entitled to try experiments as to how little space will suffice for a car to get by. If foolish or malicious driving of a vehicle caused a motorist damage, the driver must answer for it, though the motorist might have lost his head or acted hastily, thereby perhaps contributing to the accident. The driver had no right to deliberately put anyone in a difficult position where, unless he was absolutely cool and courageous, an accident might occur. Again, no one was entitled to take advantage of another person's neglect and ride over him. If a driver shouted and another did not hear him he must stop to avoid the threatened accident. If he was going too fast to stop, it was evidence of contributory negligence on the part of the driver. A driver was bound to have his vehicle in proper order. Supposing he had no brake, that was evidence of negligence, and would turn almost conclusively against him. A driver, however, was not liable for a latent defect in the workmanship or in the material of the machine which caused an accident. To leave a car unattended on a public thoroughfare might be negligence. Suppose two children commenced to play with it and one of them started it, and somebody was thereby hurt, the owner of the car would be liable. Again, if a mischievous person removed a car that had been left at the roadside unattended and placed it in the roadway, whereby an accident resulted to somebody coming along the road, the owner of the car would be liable for the damage done as well as the mischievous individual who removed it. Finally, it could not be too clearly or widely recognised that no action lay against a road authority for the bad state of the road or for any accident arising therefrom.

◆ ◆ ◆

A Dictionary of Motoring.

MR. R. J. MECREDY has been well advised in issuing in volume form the dictionary of motoring, which ran through some issues of his Journal. Since they appeared the pages have been brought well up to date, and the book should be of value to motorists, both novices and experts. The arrangement is alphabetical, and the pages contain full definitions of every term used in motoring, with special articles on roadside troubles, electric ignition, and similar important subjects. The illustrations and explanatory diagrams are extremely clear, and add much to the lucidity of the letterpress. Altogether the book is the most practical of the kind yet brought to our notice, and Messrs. Mecredy, Percy and Company, Limited, should find the demand quickly run this dictionary of motoring into a second edition. As an instance of the completeness with which the book has been written, we may mention that the chapter on roadside troubles, occupies some seventy-five pages, and apparently deals with nine hundred and ninety-nine of the thousand difficulties which beset motorists when on tour.

◆ ◆ ◆

The Side-Slip Test.

THE track at the new works of Messrs. Clement Talbot, near Ladbrooke Grove, W., where the side-slip competition will take place, is of wood pavement, which will be made greasy. The cars will have to make a right-angle turn on the grease, to describe "S" curves, and also to be subjected to brake tests. The power absorbed by the device will be tested by running the car down hill by gravity, both with and without the device fitted, and measuring the distance between the stopping places in each case. Points will be given for ease of attachment and renewal, and for price, and a device which gives the best control of the car under all possible conditions—that is to say, whether for side-slipping of front or back wheels, or of forward skidding—will be considered the better. Eighteen cars will actually take part, and each of these will carry a hon. Observer throughout the whole of the 1,000 endurance miles to see that nothing is done to the device.

BELGRAVIA GARAGES, LIMITED, has been registered with a capital of £1,000.

THE Brush Electrical Engineering Co., Limited, are about to open a showroom at 105, New Bond Street, London, for the sale of Brush cars.

THE 90-h.p. Panhard racer on which Mr. D. M. Weigel last year established some new records has been converted into a four-seated car, and has been acquired by the Honourable Maurice Egerton.

UNDER arrangements with "Automobilia," Messrs. Laing, Waters, Furnivall and Company have commenced periodical auction sales of motor-cars on the premises of the former concern in Oxford Street, W.

THE Duke of Sutherland has been elected president of the Automobile Club of Great Britain and Ireland, and the following will act as vice-presidents:—The Earl of Dudley, Lord Lieutenant of Ireland; the Earl of Onslow, Minister of Agriculture; Lord Stanley, the Postmaster-General; and Sir David Salomons, Bart. The new chairman is Lieutenant-Colonel H. C. L. Holden, R.A., F.R.S., superintendent of the Royal Gun Factory at Woolwich.

Mr. Carnegie's Motor House.

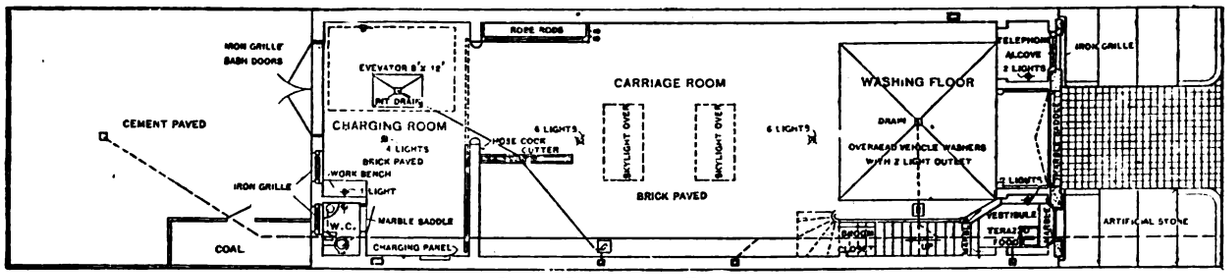

Fig 1.—Plan of Motor House.

EIGHT thousand pounds is not a very considerable sum to Mr. Andrew Carnegie, who has made dozens of presents of libraries to various communities, endowed universities, and in a hundred ways endeavoured to share his wealth with the world, but it is a large amount to spend at his initiation to the ranks of automobilists. Mr. Carnegie is noted not only for his generosity but for his economy as regards the expenditure of money for his own pleasures, and so the outlay may be said to be a considerable one, half of it going for five cars which he will keep for his use and the balance for a motor-house which will be erected close to his new residence on upper Fifth Avenue, New York.

Contrary to the usual practice of buying cars and afterwards looking out for their care and storage, Mr. Carnegie is taking up both details at the same time, and it is understood that his five new cars will be delivered by the manufacturers direct to his new motor-house.

The cars which he has purchased are all electrically propelled, selected with regard to their serviceable qualities and special fitness for town use.

The plans for the motor-house, which will be located at 55, East 90th Street, New York, comprise a three-storey building 25 feet wide by 70 feet deep. The front will be of standard Dutch red brick, laid in English cross bond with recessed joints and marble trim. The entire ground floor is to be given over to the storage and care of the cars. The upper storeys will be fitted up in the front for living apartments for the mechanicians and drivers, with sitting rooms, bedrooms, bath and kitchen. The rear portion of the second storey will be used for the storage of extra vehicles or cars of visitors, with a large lift for easy access thereto.

The walls of the first floor will be lined with white enamelled brick and the entire floor will be paved with Flintic tiles, a French material affording a surface easily cleaned and with acid resisting qualities. A hydraulic lift is one of the innovations projected for use in the inspection pit. In the charging room, which is 14 ft. by 23 ft. 4 in., is the usual charging panel, lift, pit, work bench, and lavatory. Large double doors open from the charging room on to the cement-paved yard at the rear.

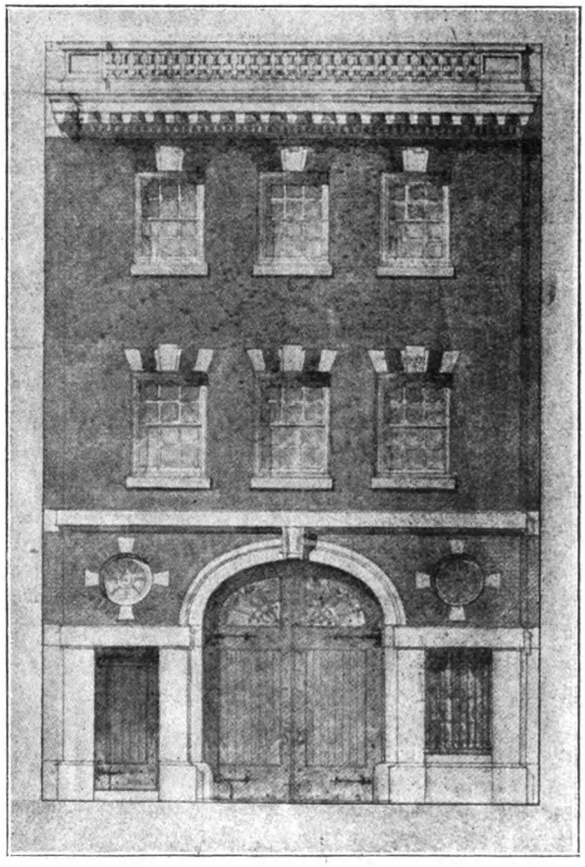

Fig. 2.—View of Exterior.

The front pavement will be granolithic; all outside wood work will be of oak with hand-wrought fittings and the double doors will have leaded lights with antique hinges and handles. Among the conveniences provided is, states the "Automobile," a telephone at the right of the entrance door, and a closet for the storage of lap robes.

The building throughout will be of Roebling fireproof arch construction, and all details of outside finish will be carried out in cut stone. The estimated cost of the building is £4,000.

MESSRS. PETO AND RADFORD, LIMITED, have issued a new catalogue of their electric storage batteries. This is arranged upon a good plan, facilitating reference and giving the user exactly the information he wants, but which has hitherto not been obtainable in so convenient a form. Specifications are given of each type of accumulator made by the firm, and these set forth the size, ignition capacity, both nominal and actual, weight, charging rate, and mileage capacity. The armoured accumulators of the firm are dealt with in the same way. Illustrated particulars are also included of the P.M. sparking plugs, the "Compound" sparking plug, the "Perfect" terminal, voltmeters, and other accessories.

MESSRS. STARLEY, LIMITED, has been registered to manufacture and deal in motors, etc.

THE United Motor Industries, Limited, have just issued a supplementary list of low-priced voltmeters, amperemeters, charging boards, and charging apparatus, known as the "F.A." series. The articles appear to be excellent value at the prices charged.

THE Devon Engineering Company, Limited, has been registered with a capital of £5,000 to acquire the business of the Devon Engineering Company, and part of the assets of the Devon Traction and Motor Company, Limited, to adopt an agreement between Messrs. W. J. Dart, P. C. Noble, and J. E. Parnell of the first part, Mr. G. T. Clarke of the second part, the Devon Traction and Motor Company, Limited, of the third part, and Mr. C. A. Pooley (for this company) of the fourth part, and to carry on the business of mechanical engineers, makers of motors, etc. The office is at Harbour Works, Paignton.

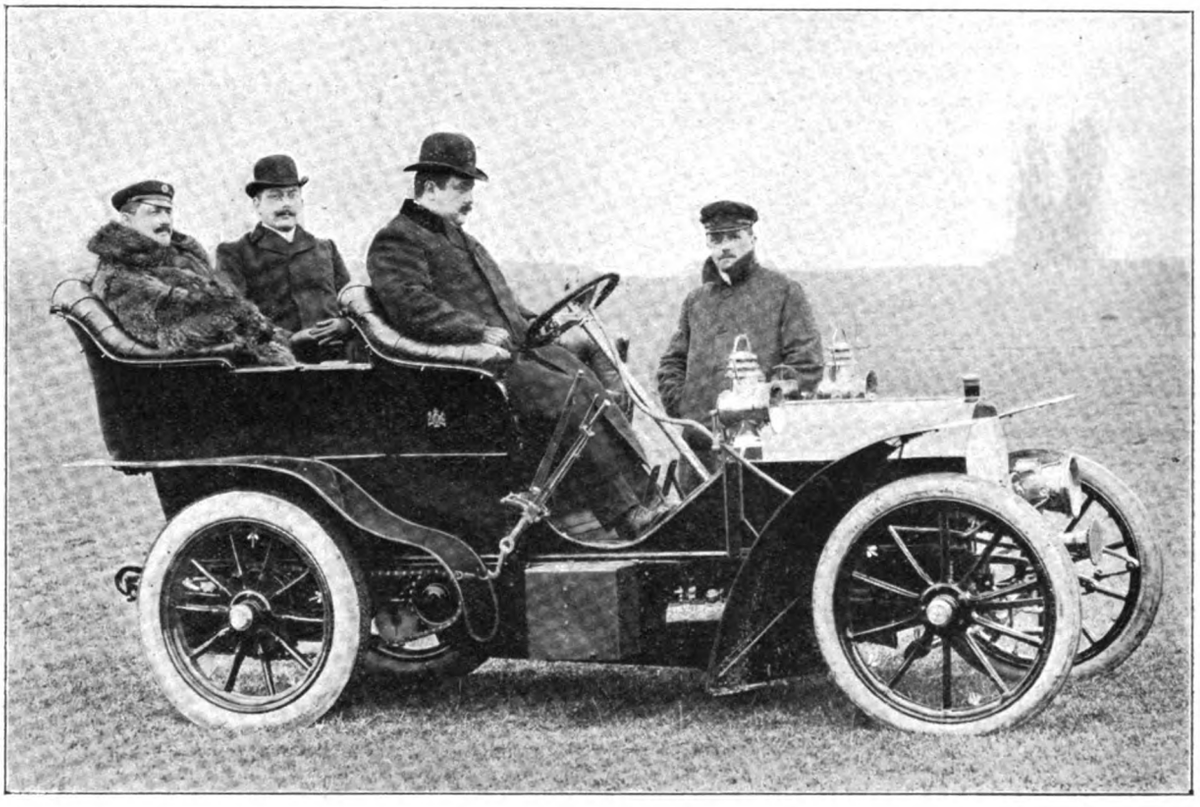
CONTINENTAL NOTES.

IT is announced that arrangements are being made to open the Gordon Bennett Cup course to competitors for one month previous to the contest, in order to allow them to study its peculiarities. The teams will probably be permitted to make high speed runs over the route from 11 to 3 o'clock each day, and special precautions will be taken by the authorities in the villages and at the sharp corners, etc., *en route*. Extra expense will be incurred on this account, and the competitors who use the course will be asked to defray it. A number of regulations have been drawn up concerning these trials, and should any driver cause a fatal accident all the cars belonging to his firm will be debarred from taking part in the great event. It is announced that the municipal authorities of Bingen have offered to place at the disposal of the Gordon Bennett race organisers a large building capable of accommodating at least 200 motor-cars. The town is about forty-five miles from Homburg, and it is stated that there are many well-equipped hotels there, where accommodation can be obtained at moderate prices. It is also stated that there are plenty of rooms still to be had in Darmstadt, which is only about twenty-five minutes' run from Frankfort. The Motor-Cycle Union of the Austrian Automobile Club has decided to organize a tour to Homburg on the occasion of the Cup race.

◆ ◆ ◆

IT is reported that the F.I.A.T. Company are building six cars for the Italian team in the Cup race. Three will be of 65-h.p., and three of 105-h.p. The actual competing cars will be selected after all the vehicles have been submitted to trial on the road.

◆ ◆ ◆



A NOVEL competition was held on Sunday last by the Antwerp Automobile Club. It was known as the "Course à l'Envelope," seventeen competitors taking part in it. Each was given a sealed envelope in which a village about ten miles away was named; they had then to drive to a café at this place, where they were given a second envelope containing fresh instructions. Altogether fifty kilometres were covered, the mysterious course being traversed in one hour thirty minutes by the winner, M. Joostens, on a Talbot car.

◆ ◆ ◆

THE Cannes Automobile week is now an event of the past. On the 15th inst. there was a series of mile trials and a hill-climbing competition. The best time for the mile was made by Mr. A. Burton, who, on a 130-h.p. Gobron-Brillié, covered the distance in 46 3-5 secs., equal to over 78 kilometres per hour. M. de Cesti on a 60-h.p. Mercedes was second in 48 1-5 secs. The hill-climb was over a 500-metre course of an average gradient of 8 per cent. and this also was won by Mr. Burton in 33 2-5 sec. or a speed of 54 kils. per hour. On the 16th a consumption trial was held, the competitors being each allowed a litre of essence. A Clement machine made the best distance in the motor-cycle class, covering 29 1-4 kil., a Renault light car did 14 3-4 kil., a Peugeot in the 650-1,000 kilog. class did 11 1-4 kil., while the best in the heavy car class was a Rochet-Schneider which had 6·3 kil. to its credit.

◆ ◆ ◆

THE Nice automobile week commenced on Tuesday by a touring competition over an 180-kilometre route. Among the entries were M. de Bary (18-h.p. Mercedes), M. Clerissy (Rochet-Schneider), M. Millo (14-h.p. Renault), Prince Lubecki (60-h.p. Mercedes), and Mr. C. Gray Dinsmore (60-h.p. Mercedes).

King Edward's Newest Car—a 1904 18-24 h.p. Mercedes. (*See page* 61). [*Allgemeine Automobil Zeitung.*

◆ ◆ ◆

THE municipal authorities of Spa, Belgium, have voted a sum of £500 towards the expenses of the "Automobile week" which is being organised by the Automobile Club de Spa.

◆ ◆ ◆

M. DE MOT, the Burgomaster of Brussels, has invited the Belgian Automobile Club to organise a fete next year in celebration of the 75th anniversary of the national independence.

◆ ◆ ◆

IT is proposed to organise an international motor-car service between Aosta, Italy, and Moutiers, France, via Pre-St. Didier, Seez, Bourg St.-Maurice and Aimé. The vehicles used will be 16-h.p. and 24-h.p. de Dietrich omnibuses.

◆ ◆ ◆

A 400-KILOMETRE automobile test, termed the Circuit du Pas de Calais, is being organised in connection with the exhibi-

Digitized by Google

tion to be held at Arras in May. This event will be open only to small cars weighing under 400 kilogs. and to motor-bicycles. The trial will include hill and speed tests, but no average speeds for the entire run beyond 30 kilometres per hour will be recognised.

◆ ◆ ◆

DETAILS of the various French cars for the French Gordon Bennett eliminating trials are gradually leaking out. It has already been stated in this column that the Panhard cars will, for the first time, be of the chainless variety. The 1904 De Dietrich will for the most part be similar to those which took part in the Paris-Madrid race, except that they will be slightly longer. The steering column will be more inclined than before, while it is reported that the engines will develop about 80-h.p. The Georges Richard Company are building three light racers, the four-cylinder motors of which are expected to develop about 75-h.p. The cars will be chain-driven, with direct drive on the top (third) speed. A novel feature will be found in the clutch, which will be of the usual leather-faced cone type, but with the addition of a positive drive which may be put into gear by means of bolts which slip into corresponding holes in the flywheel.

◆ ◆ ◆

TO utilise the energy stored in the exhaust gases, a French engineer, M. Chevalier, has hit upon a method which he deems practicable. He utilizes the flame which rushes through the exhaust port of one cylinder to ignite the fresh charge in another cylinder, and thus, of course, his plan is workable only with multiple-cylinder engines. By connecting a series of small tubes with the exhaust valves, and joining up one cylinder with another M. Chevalier has contrived that portion of the exhaust gases from one cylinder will rush as a tongue of flame into the next cylinder at the proper moment and explode the charge. When this cylinder is fired it will similarly send a flame into the next cylinder, and thus the process goes on. Valves worked from the cam shaft govern the time of the flame entering the cylinder, and by a simple and ingenious arrangement this time can be advanced or retarded, thus altering the time of firing as in electric ignition. On starting the engine the first explosion is caused by an electric spark or other device, and after that the automatic firing comes into use. It remains to be seen how the new arrangement will work in practice.

◆ ◆ ◆

AN International Automobile Exhibition was opened at Frankfort-on-Main on Saturday last. It is being held under the auspices of the Germain and Frankfort Automobile Clubs, and is proving a great success, there being close upon 200 exhibitors. All the leading German makes of cars are on view, as well as the majority of the principal French types. The exhibition remains open until the 27th inst.

◆ ◆ ◆

THE automobile week at Ostend is to be held from the 15th to the 21st July next. On the first two days there will be a touring competition, while on the 17th July a series of kilometre and mile speed trials will be held. On the 18th there will be a fifty kilometre race between Ostend and Blankenburg, while the 19th and 20th will be devoted to a second touring trial. A driving competition will be held at the Hippodrome, Ostend, on the 21st July, and on the 22nd a start will be made for Namur, where the automobile sports will be continued.

◆ ◆ ◆

THE Motor Club of Nice has decided to organise a reliability trial for motor-cycles and cars. It will probably be held on the 9th of June.

◆ ◆ ◆

THE Swiss postal authorities are about to make some trials in Berne with an Orion motor-wagon, having a carrying capacity of 1½ tons.

IT is satisfactory to learn that British makers of motor-cycles are already cultivating foreign trade. The official returns for the two months ending with February, now available, show that during that period 161 machines valued at £6,147 were exported. The shipments of motor-cycle parts amounted to £853, giving a combined total of £7,000.

THE MOTOR CAR ACT.

Transfer of Registration.

P. P. writes:—Will you advise me through your paper as to the following point. If I purchase a second-hand car which has been registered, I can by paying five shillings have the number transferred to me. Kindly say if I must pay the five shillings in my own town or where the car came from."

◆ ◆ ◆

When buying cars we should advise the purchasers to suggest that the sellers should see to the transfer of ownership being effected. This would save much trouble provided the new owner was satisfied as to the proper entry of all the necessary particulars. When the ownership of a car is changed notice of the fact must be given to the Council with whom the vehicle is registered and an application made either to cancel the registration or to continue the same under the new ownership. Should the buyer register the car in his own place, the application will be treated as a new registration.

◆ ◆ ◆

Motoring in Egypt—At the Foot of the Great Pyramid of Cheops.

Numbers of the Home Counties.

A. G., who frequently sees cars with various numbers passing through London, asks for the numbers of the places near the Metropolis.

◆ ◆ ◆

A full list of the numbers for England and Wales appeared in our issue of November 28th last. The following are given in response to the foregoing request:—London County Council, A; Kent, P; Essex, F; Middlesex, H; Surrey, P; East Sussex, A P; West Sussex, B P; West Ham, A N; Croydon, B Y; and Reading, D P.

◆ ◆ ◆

A Suggestion.

"No doubt," writes an Eastbourne correspondent, "it must have occurred to others, but it seems to me that instead of the present letter numbering, if the word shire were dropped each county could be lettered with its first and last letter without any confusion or duplicating, *e.g.*, D.Y., Derbyshire; D.N., Devonshire; S.P, Shropshire; S.D., Staffordshire; and so on."

◆ ◆ ◆

THIS idea was suggested a few months ago, but the Local Government Board apparently preferred the haphazard arrangement that now confuses everyone in place of the sensible suggestion of facilitating identification by giving the letters some readily recognised geographical significance.

D

THE MOTOR VOLUNTEERS.

PROGRESSIVE has been the career of the Motor Volunteer corps since Mr. Mark Mayhew, then an officer in the Imperial Yeomanry, gave automobile assistance to Sir Evelyn Wood and Sir Redvers Buller at the Aldershot manœuvres three years ago. This branch of the Volunteer Army has received full recognition from the War Office, its officers have been officially presented at a Levee, and altogether the favour which has been bestowed upon the corps must have been particularly gratifying to those who have devoted time and trouble to furthering its fame.

Since September last the Motor Volunteers have been continuously busy, and, although some of the services have been of the Carter, Paterson variety, other shave been of real importance and value to the military authorities. Staff officers have been enabled to undertake extended rounds of inspection in the minimum time, and it has been conclusively shown that the automobile can be relied upon in cases of emergency. For March no fewer than seventy cars have been requisitioned for service, and at the end of the month some particularly interesting work will be given the Corps. The London defences are to be visited for the purpose of conducting the Scottish Volunteer officers over them. These are practically unknown to the general public, so that those motorists who have enlisted in the Volunteers will be given an insight into military matters that should add a zest to their enthusiasm for the movement. On the 28th to 30th the corps will take part in a staff ride in connection with the Staff College in the neighbourhood of Brighton. During the past few days some of the Motor Volunteers have been taking part in a staff ride under the general officer commanding the 1st Army Corps, in the neighbourhood of Chichester, while the first days of March were occupied in a reconnaissance for officers of the Royal Artillery at Woolwich.

Some information with regard to the *personnel* of the corps will be of interest. Lieut.-Col. Mark Mayhew, the commanding officer, is not only an enthusiastic advocate of our citizen army and a motorist who has driven cars from the early days of the modern movement, but he has also encouraged the purely utilitarian aspect of automobilism, as can be seen from a visit to Battersea, where the name "Mark Mayhew, Ltd.," can be found inscribed on heavy lorries which are conspicuous in the traffic of those parts. Captain G. Skeffington Smyth, D.S.O., who served with distinction in the South African campaign, is adjutant.

For the purpose of organisation, the country has been divided into commands and sub-commands as follows:—Major W. G. Windham is in charge of the London district, which is divided into sub-commands for London (5 officers and 25 members), Hounslow (2 officers and 6 members), Oxford (1 officer and a member), Woolwich (1 officer and a member), Kingston (2 officers and 3 members), Reading (1 officer and 1 member), Colchester (1 officer and 7 members). In the Aldershot command there are 2 officers and 3 members. The York command is divided into two districts, with York and Chester as headquarters, the present composition of the command being three officers and sixteen members. Naturally the south and west of England supply a goodly contingent of these motoring volunteers. Major J. M. Benett-Stanford is in charge of the Salisbury command, which has sub-divisions with head-quarters at Plymouth, Portsmouth, and Dover, the responsible officers being Lieut. O. H. Bayldon, Captain A. H. Lee, M.P., and Captain E. Midgley respectively. In this command there are three officers and twenty-five members. Scotland supplies two officers and a member and there are two officers and two members in Ireland. These with four other members constitute the strength of the Motor Volunteers.

MOTOR-CYCLING NEWS.

THE Ormonde Motor Company have just issued a very useful descriptive handbook of their Kelecom motors and Ormonde motor-bicycles. Illustrations and descriptions are given of the various parts of the motor, such as the contact maker, carburettor, switch, chain, belt, etc. The Ormonde complete machines — motor-bicycle, tri-car, and side car, are also fully dealt with.

◆ ◆ ◆

CONSIDERABLE discussion is now taking place in motor-cycling circles anent chain-driven motor-cycles, and also as to devices destined to prevent any jerky action due to the impulse stroke of the motor being transmitted to the chain and rear wheel. The accompanying illustrations of the friction clutch and spring wheel used on the machine built by Messrs. Bruneau of Tours, France, will therefore not be without interest. The machine itself follows the usual arrangement of motor-bicycles, the 2½-h.p. air-cooled engine being located in a vertical position, just forward off the bottom bracket. Fig. 1 gives a sectional view of the clutch, which is mounted on the engine shaft. *a* is a leather-faced cone running loosely on the shaft *d* and having rigidly attached to it the chain wheel. The female part of the clutch *b* is fitted on the motor shaft, which at its end is made square instead of round. A spring *g* is held between the cap *f* and the part *b* of the clutch. By means of a lever on the

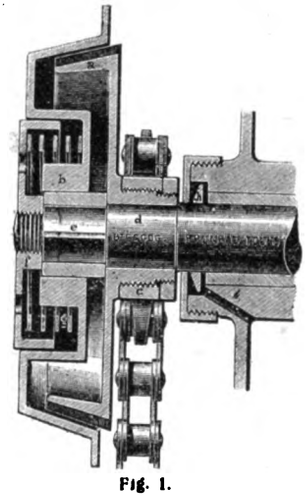

Fig. 1.

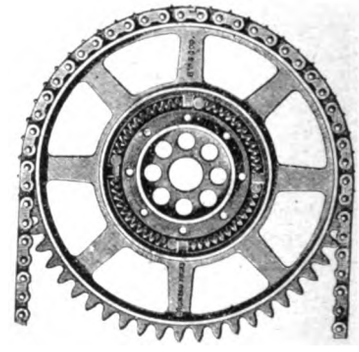

Fig. 2.

top bar of the frame the spring *g* can be compressed, bringing the two frictional surfaces of the clutch together at will. Fig. 2 depicts the Bruneau spring chain wheel connected with the rear road wheel of the machine. As will be seen, the wheel is made in two parts, the outer portion being so fitted that it can slide round a disc attached to the hub of the wheel. In a channel in the disc are fixed four spiral springs with which projections on the outer part engage. In starting a machine there is, of course, a tendency for the driven chain wheel to run faster than the road wheel to which it is connected, and it is to allow for this that the springs are introduced. Until the speed of the road wheel is equal to that of the sprocket any difference is taken up by the compression of the springs. When equilibrium is attained between the two wheels, that is to say, when they are both running equally fast, a condition which is reached after a few revolutions, the springs are no longer called into action.

THE Manchester Motor-Cycle Club hold a social gathering on Friday of this week at the Blackstock Hotel, Upper Brook Street, Manchester, when a lecture will be given by Mr. J. T. Ward on "Desirable Improvements in Motor-Cycles," after which a discussion will be held. The club is also organising a four days' tour in North Wales, the first day's journey being on Good Friday to Bangor, where the further excursions will be decided upon by those taking part in the tour.

Digitized by Google

HERE AND THERE.

POWERS are being sought by the Cambrian Railway Company to run motor-cars.

MAJOR COURTENAY MORGAN has ordered from the British Automobile Commercial Syndicate, Limited, a 24-h.p. "Fiat" car.

THE Highgate Bench has threatened to deal severely with cases in which motorists are summoned for having no lights on their cars or cycles.

THE Newport (Mon.), Watch Committee have now decided to impose the ten mile limit only between the town end of the Cardiff Road and Clarence Place.

MR. H. RAMOISY, who has for some time been connected with the London Motor Garage, Limited, is now devoting his attention to Germain cars, he having transferred his services to Captain Theo Masui.

A CATALOGUE of their motor clothing has been issued by the North British Rubber Company, Limited, who are going thoroughly into this department. Included in the illustrations and descriptions are motor-car covers, flexible buckets, rugs, overboots, and other accessories.

ONE firm, recognising the attractive properties of the Airship section at the Show, invested in some of the elephant balloons of Messrs. Spencer, and having placed them on the driving seats of their vehicles, have apparently sought thus to demonstrate the simplicity of the steering mechanism.

THE Brown and Sharpe Manufacturing Company, of Providence, R.I., U.S.A., the well-known makers of machine tools, are now turning their attention to the production of spur and bevel gears for use on motor-cars. Cylinder castings is another branch of automobile work which has been taken up by this concern.

DURING the first hours of Saturday the fitters engaged in connection with the construction of the stands at the Exhibition found their resources fully taxed, the large number of exhibitors having apparently taken them somewhat by surprise. This feeling seems to have been general throughout the stand-fitting trade, and there is no doubt that rarely before have those who have arranged stands for exhibitors at the Agricultural Hall been so busy.

AMONG the minor matters of transient interest in connection with the Exhibition must be mentioned the enterprise of Messrs. Dunhill, Limited, who every year seem to have some new idea for attracting attention to their display. "Living pictures" have again appeared, whilst the tall man of a year ago is now accompanied by two small boys, whose facial adornments add a solemnity to their appearance which has proved amusing to visitors.

THE Rex Patents, Limited, have lately brought out a combined carriage clock and speed indicator for use on motor-cars. Briefly, it is a combination of a carriage clock showing the time in the usual manner with an additional hand or pointer indicating the speed in miles per hour. The speed pointer indicates on a separate circle of figures ranging from 10 to 60 miles per hour. The figures are clear and bold and easily read at some distance. The instrument is constructed to operate from one milestone to another, or known distances of a mile, such as can be afforded by the signal cyclometer, or a cyclometer in view of the motorist. The combination can be fitted anywhere on the car, and there are no connections to make and no attention required beyond the daily winding of the clock. The indicating hand is normally at zero, a pressure on the brass slide at the side of the clock starts it, and on the completion of a mile the hand will indicate the exact speed in miles per hour at which the car has travelled. A second pressure on the stud in a reverse direction returns the hand to zero. The clock runs independently of the speed hand and indicates the correct time whether the latter is used or not.

AN automobile club has just been formed at Genoa, Italy.

FROM the Non-Skid and Non-Puncturable Tyre Company, Manchester, comes a circular of a tyre fitted with a corrugated steel tread which is claimed to give full protection to the tyre.

AN American contemporary defines a patent as a sort of thing that gives one person the exclusive right to all the litigation in connection with some sort of a thing for a certain number of years.

THE Electric Ignition Company, for whom Messrs. Brown, Bros., Limited, are wholesale agents, send a catalogue of their sparking coils, contact breakers, accumulators, switches, and other electrical accessories for automobiles.

OWING to the increase of business, the Forman Motor Company, Limited, are removing from Day's Lane to larger premises in High Street, Coventry, and from the 25th inst. all communications should be sent to the new address.

WE learn that Messrs. Van Raden and Company, Limited Coventry, have received the orders for high-speed coils and woven glass accumulators from the Wolseley Motor-Car Company for use on their 1904 Gordon Bennett racers.

MESSRS. ARMSTRONG, STEVENS AND SONS, of Birmingham have issued a catalogue of motor fittings for the coming season. Their work is characterised by general excellence, and in tubular radiators and bonnets are some good designs of interest to makers of cars.

MESSRS. G. T. RICHES AND COMPANY have just issued a new catalogue of spare parts and accessories for all the leading types of motor-cars. The list, which extends to eighty pages, is conveniently arranged and provided with an index, which considerably adds to its usefulness.

The Gordon Bennett Race.—A View near the Starting Point at Saalburg.

WHAT is claimed to be the fastest performance ever made by a woman on a motor-car has, according to telegraphic advices from New York, just been achieved by Miss Leah Russell, who drove the racing car known as "Ford 999" a straightaway mile in 53 1-5sec. under the observation of official timekeepers.

MR. HENRY SPURRIER, JUN., of the Lancashire Steam Wagon Company is about to visit the United States, with a view to a study of the engineering methods in certain American industrial establishments, and a survey of the problem of heavy motor traffic as it confronts the Americans.

THE start of the Whitsun run to Edinburgh of the Motor-Cycling Club is fixed for 10 p.m. on Friday, May 20th, from the G.P.O., London. Those riders who reach Edinburgh within twenty-four hours will qualify for a special badge and club certificate, while those who reach the Scottish capital within thirty hours will be awarded certificates, setting forth the actual performance.

The Motor-Car Exhibition at the Agricultural Hall.

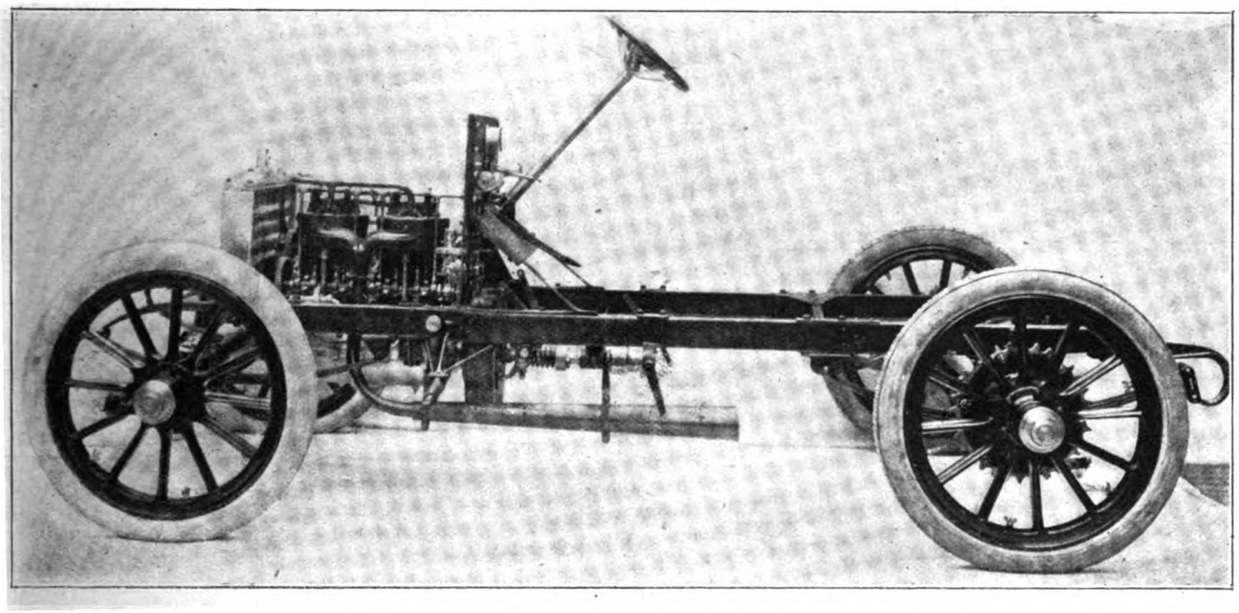

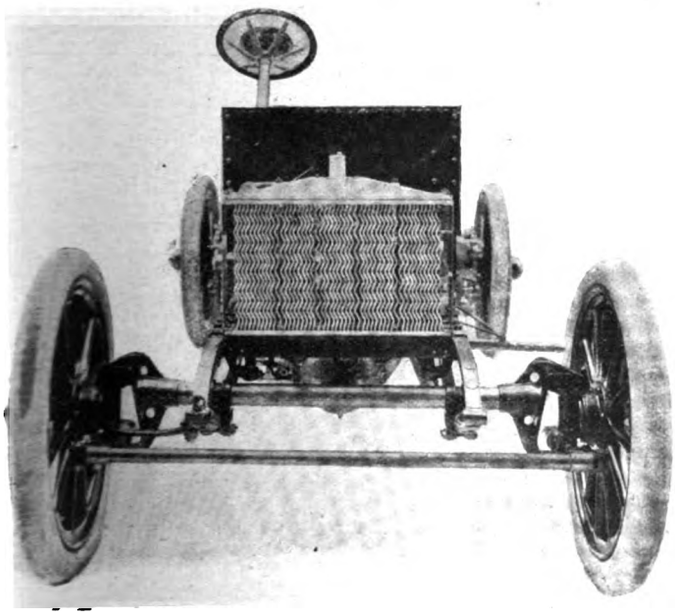

Fig. 1.—Chassis of the Hutton 20-h.p. Car, showing New Silencer.

BELOW we commence our review of the Motor Car Exhibition now in progress at the Agricultural Hall, London—an Exhibition which in the number of exhibitors and variety of automobile exhibits exceeds anything previously seen in this country. On all hands Mr. Charles Cordingley has been congratulated on the comprehensive character of the Exhibition, and so satisfactory has been the business done that many firms have already booked space for next year's show. Obviously it

g. 2.—Front View of Hutton 20-h p. Chassis, showing New Radiator and arrangement o Front Axle.

is impossible to deal with all the exhibits in one issue of the *Journal*, but exhibitors and readers alike may have an assurance that no stand will be unnoticed, and that reference will be made to the many features of real interest and value.

PETROL CARS.

One of the *clous* of the Exhibition is undoubtedly the *chassis* of the new 20-h.p. Hutton car shown on the stand of Messrs. J. E. HUTTON, LIMITED. The car, which is constructed in accordance with Barber's patents, has a frame of pressed steel. The engine has four cylinders cast in two pairs. The valves are mechanically actuated off one cam shaft; the inlets, which are located on the top of the cylinder heads, are provided with a variable lift device. The governor is mounted on the half-speed shaft. The cylinders are 90 mm. diameter by 124 mm. stroke, the normal speed being 1,000 to 1,200 revolutions per minute. The radiator (Fig. 2) is of novel design, and made of aluminium; it consists of a large number of tubes bent to a special shape, and arranged in five groups; it is stated to be very efficient, while its weight is only 30 lbs. The pump is gear driven, and the ignition is by means of a chain-driven magneto.

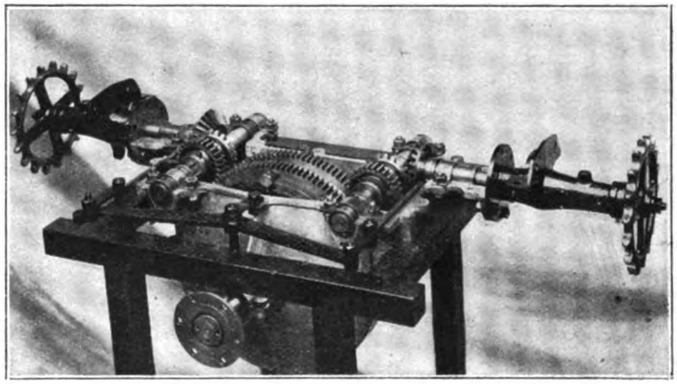

Fig. 3.—The Barber Variable Speed Gear used on the Hutton Car.

The carburettor is of novel design and automatic in action; the governor is connected up to it in such a way that when the speed of the engine becomes excessive more air is admitted, with a corresponding reduction in the degree of suction of the petrol. The valve stems are lifted by steel balls instead of the usual rollers. The motor itself is supported on the frame through four square spiral springs, which take up any vibration due to the engine. The exhaust box, too, is of original design. It consists of a taper pipe, the outer end having the largest diameter. The pipe itself has a series of holes pierced in it, through which air is drawn in and mingled with the exhaust gases, which have a straight outlet from the motor, without meeting

Digitized by Google

any baffle plates on their way to the atmosphere. A Barber variable gear (Fig. 3) is shown separately; this is quite a radical departure, and cannot be well described without drawings. It must suffice for the moment, therefore, to say that it gives infinite variation of speed between zero and the maximum, this being obtained by means of a variable throw eccentric on the driving shaft. To this are pivoted a series of arms, at the outer end of which are shoes, the faces of which, like the brake shoes, are provided with V-shaped projections, fitting into corresponding grooves in the discs surrounding the eccentric. The rotation of the discs is obtained

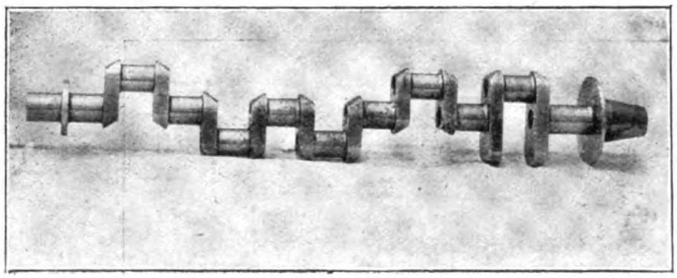

Fig. 4.—Crank Shaft of the Hutton Five-Cylinder Gordon Bennett Racer.

by a series of rapid pushes, one shoe after the other taking up the drive at rapid intervals. The periphery of the two discs, which travel in opposite directions, is provided with spur teeth, each disc meshing with its own pinion on a side shaft. On the rear ends of the latter are bevel pinions gearing with bevel wheels on the cross shaft. On the ends of the latter are sprocket wheels, which convey the power to the rear road wheels by side chains in the usual way. To obtain the reverse motion, the spur pinions, which are free to slide on their shafts, are each disengaged from their discs and brought into mesh with the other. The brakes on drums on the rear wheel hubs are actuated hydraulically, they each having in conjunction with them a cylinder and piston, which, when the oil is admitted to them, recede from one another. When the oil pressure is released a small spring lifts the band off the drum. A pedal controls expanding band-brakes on the inside of the same drums, the latter having V grooves into which fit corresponding projections on the brake shoes, the contact surface being thus increased. The brakes are metal to metal, and work in oil. The oil supply to the variable speed gear is controlled by two

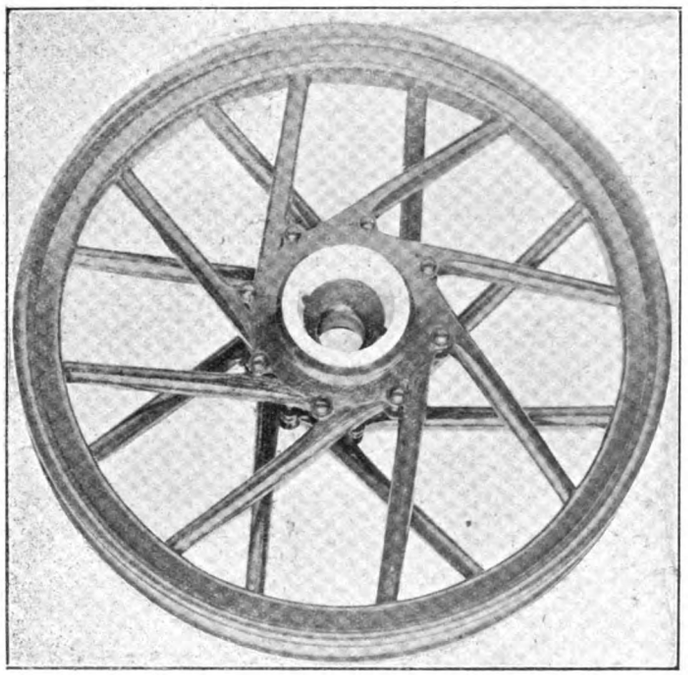

Fig. 5.—Tangent Road Wheel for the Hutton Gordon Bennett Racer.

buttons on the steering wheel. Sufficient oil is contained under a pressure of 300 lbs. per square inch, in a special reservoir on the dashboard, for three charges of the hydraulic brakes, while the variable-speed gear is kept full. The starting handle, contrary to the usual practice, is at the side of the car. The front and rear axles are of straight nickel steel tube of large diameter, supported directly on the springs. The road wheels run on ball-bearings, 1 in. balls being used for the front wheels, and 1¼ in. for the rear. The steering gear is of strong construction, the standard having a ball bearing. The front steering rod is of large diameter tubing. The steering pivots have plain bearings at the bottom and ball bearings at the upper end. A spring buffer box is introduced into one of the steering rods to take up any shock.

The crank shaft of the Hutton car for the Gordon Bennett race is also on view. An illustration of it is given in Fig. 4. Contrary to expectations, the new racer will have a five-cylinder engine. It will be noticed that one of the cranks is fitted with counterweights, these being intended to balance the action of the throw of the eccentric in the variable speed gear. It is interesting to add that as regards the working of this large engine, which is expected to develop about 100-h.p., the two outer cylinders will be fired simultaneously, the two plugs being arranged in series to obtain synchronous sparking. After cylinders Nos. 1 and 5 have fired, Nos. 2, 3, and 4 follow in the usual order. The mixture for the five cylinders will be furnished by two carburettors. Fig. 5 shows one of the wheels intended for the Hutton Gordon Bennett racer. As will be seen, it is of the tangent type, each of the wooden spokes being entirely in compression. The design is such that a wheel of extreme rigidity is obtained, and one capable of withstanding all possible side strain. Altogether, the new Hutton cars bristle with novelties, the behaviour of which on the road is being looked forward to anxiously by all motorists. Messrs. Hutton also have an excellent display of Panhard cars of the 8-h.p. three-cylinder and 10-h.p. and 20-h.p. Panhard cars, as well as a 12-14-h.p. Brooke car, with tonneau body.

Messrs. Deasy and Co. have on view a *chassis* and complete tonneau of the Martini car, which, since Captain Deasy drove one up the cog railway on the Rochers de Naye, near Caux, have come rapidly to the front. For 1904 only one type is being made, a 16-20-h.p. four-cylinder vehicle; the engine, although on the same lines as last year's model, being slightly more powerful. Mechanically-actuated inlet valves are employed, together with a combined honeycomb radiator and water tank, a feature being the provision for drawing off all the water, when necessary, from the radiator, tank, pump, and cylinder jackets. Four speeds forward and a reverse are pro-

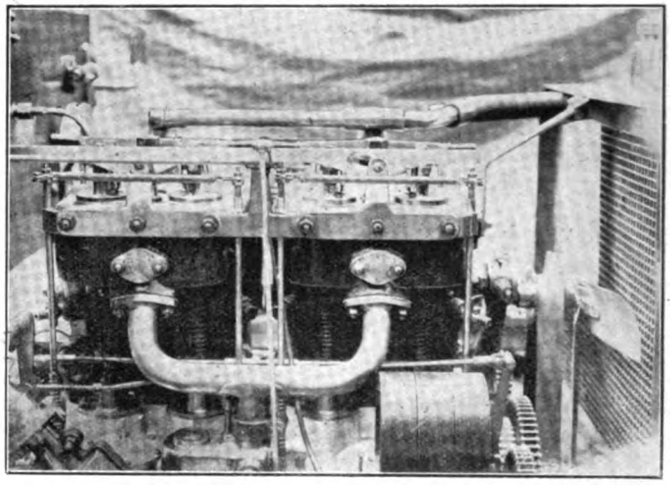

Fig. 6.—The Martini 16-20-h.p. Engine.

vided; a direct drive is obtained on the fourth, and the single lever controlling all the speeds has only a forward and backward movement. The clutch is of the leather-faced cone type, and a universal joint is introduced between it and the gear box, to prevent any strain being thrown on the latter. The main frame, as well as the secondary one supporting the engine and gear box, are of pressed steel. With the exception of one hand-controlled lubricator for the pump and radiator fan spindle, the lubrication is entirely automatic; the base chambers are provided with cocks, by means of which it can readily be ascertained whether they contain the desired amount of oil. The engine and gear box are entirely protected below, while the steering rod is placed behind the front axle, and is thus well protected in case of accident. An example of the 16-22-h.p. Rochet-Schneider cars is also to be seen at this stand.

A *chassis* and a complete tonneau of the 1904 18-28-h.p. Mercedes form the exhibit of the Cannstatt Automobile Supply Association. The principal new features of this interesting and well-known vehicle have already been dealt with in the *Journal*. We may briefly mention, however, that the vehicle varies in several details from last year's type; the engine has four cylinders, 100 mm. diameter by 130 mm. stroke; all the valves are mechanically operated and interchangeable, the inlets being on the left and the exhaust on the right, looking from the dashboard. The carburettor is located quite close to the admission ports. The magneto, which is on the right side, has in connection with it a plug switchboard, by means of which any one of the cylinders may be cut out for testing purposes. The variable lift to the inlet valves has been abandoned. The flywheel is of larger diameter than last year. The gear box shows little alteration, but an ingenious arrangement is provided for automatically opening a cock when the brake pedal is applied, allowing water to flow to the band brake on the differential shaft. The frame is somewhat longer than last year, being now 8 ft.

Digitized by Google

UNDOUBTEDLY one of the features of the Exhibition is the *chassis* of the 20-h.p. Hotchkiss car to be seen on the stand of PARIS AUTOMOBILE, over which M. Henri Fournier, the well-known racing motorist, is presiding. The leading details of the new vehicle, which is built by the great French gun-building firm of Hotchkiss, were described in our report of the Paris *Salon*. The frame is of stamped steel, and is supported on four side springs and a transverse one at the rear. The engine comprises four vertical cylinders, cast in pairs; both the inlet and exhaust valves, which are arranged on opposite sides of the cylinders, are mechanically actuated and interchangeable. The ignition is by magneto, while the water circulation is maintained by a gear-driven pump. The radiator is of the honeycomb type, of a circular shape. The tubes of the honeycomb are of a triangular section, giving a large radiating surface. The fan, inducing a current of air through the tubes, is made in such a way that the inclination of the blades or vanes can be varied from the driver's seat, and the air draught increased as desired, as, for instance, in mounting long hills. The clutch is on novel lines; it is of the leather-faced type, and is provided with a locking device which prevents any tendency to slip. Four speeds forward and a reverse are provided, the power on the top speed being transmitted direct to the rear live axle through a cardan shaft and bevel gearing. The rear axle is entirely enclosed; the case which encloses the differential and large bevel gear being divided in a horizontal, instead of, as usual, in a vertical plane, enabling the interior to be quickly inspected. The front axle is of tubular construction, and the pivots on which the front wheels are mounted lie in the centre of the hubs (Fig. 8), the arrangement being such as to provide large flat guide surfaces over and below the axle end, and the steering rod is placed out of harm's way behind the forward axle. The brake on the countershaft is of the contracting band type, and those on the rear wheel hubs of the internal expanding variety. Ball bearings are used throughout, not only for the gear-box, the live-axle, and the road wheels, but also for the crank-shaft of the motor.

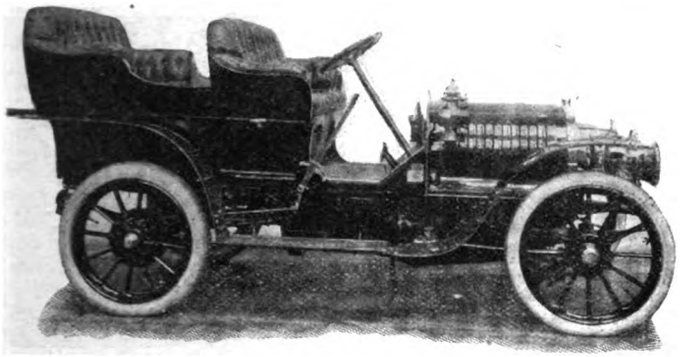

Fig. 7.—General View of Hotchkiss Car.

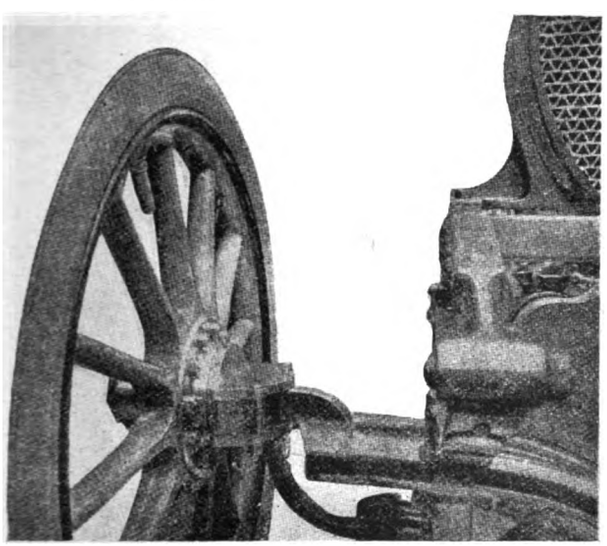

Fig. 8.—View of Steering Pivot and Part of Radiator of Hotchkiss Car.

The "National" is the name of a new British-built car exhibited by MESSRS. LAMB BROTHERS AND GARNETT, the selling agents for the makers, Messrs. Rose Brothers, of Gainsborough. The vehicle exhibited is of 10-12-h.p., but the standard type is one of 15-17-h.p., having a frame of pressed steel, to which is riveted a steel underframe carrying the engine and gear box. The motor has three vertical cylinders, 4 in. diameter by 5 in. stroke, cast separately, with combination chamber and water jacket complete. The valves are all mechanically operated off one cam shaft. The commutator is conveniently arranged in an inclined position at the rear end of the crank case, and is gear driven. The carburettor is of the self-adjusting spray type. The governor only comes into action when the maximum number of revolutions is attained, the normal speed being 850 revolutions per minute. The inlet valves are provided with a variable lift device controlled by a small lever on the steering wheel. The water circulation is effected by a gear-driven pump in conjunction with a tubular radiator. The fan which induces a current of air through the latter is designed so that the slack or stretch of the belt can be instantly taken up by a spring device. From the engine the power is transmitted by a conical friction clutch of improved design, and thence by means of large gear wheels to cardan shaft and a live axle. A feature of the clutch is that the male portion, on being released, runs idly on the gear shaft, so facilitating the changing of the gears. The gear box is made in halves—on removing the top half both shafts and gears are exposed. Three speeds forward, with direct drive on top speed, and a reverse, are operated by one lever. A double-acting metal-to-metal internal expanding band brake is fitted on the main shaft outside the gear box, actuated by foot lever. Double-acting internal expansion brakes are also fitted to each of the rear wheels, these being controlled by a hand lever. On this stand is also to be seen the body, in the rough, of a well-designed landaulet, with forward roof extension and front glass.

AUTOMOBILIA, LIMITED, confine their exhibit to a display of Darracq cars, the details of the 1904 models of which have been already dealt with in the *Journal*. One of the cars is of 15-h.p., while of the 12-h.p. type two, fitted with specially-finished tonneau bodies, painted in green, are on view. MESSRS. VAN TOLL AND CO., of Twickenham, exhibit three finished cars, viz., an 18-24-h.p. Mercedes, a 7-h.p. Panhard, and a 12-h.p. Talbot, the details of which have already been given in these columns. MESSRS. PRITCHETTS AND GOLD, LIMITED, have on view two types of their "Meteor" cars—12-h.p. and 16-20-h.p.—both fitted with four-cylinder engines. They are on standard lines, the 12-h.p. vehicles being made with cardan shaft or side chain transmission. The frames are of pressed steel; the gear box gives three speeds forward and one reverse, with a direct drive on the top speed. The motors are fitted with a special carburettor, which enables the engine to be run down to a low speed. Without comprising any startling departures from standard practice, the "Meteor" cars appear to be of sound construction.

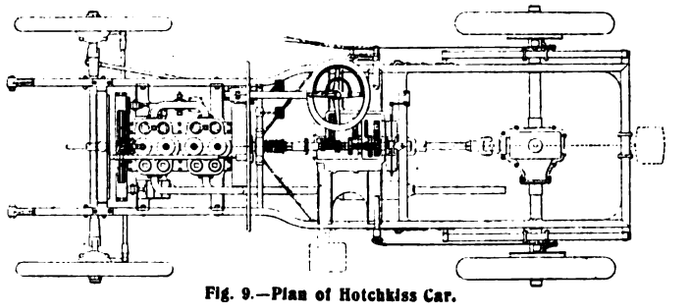

Fig. 9.—Plan of Hotchkiss Car.

The HIGHGATE MOTOR-CAR COMPANY, in addition to several Darracq cars, display a new two-seated car which they have named the "Highgate"; these follow the usual lines of cardan driven vehicles, being fitted with 6-h.p. De Dion motors. They are made in two patterns, one having two and the other three forward speeds, in addition to the reverse; they appear to be of sound construction and good value for the price demanded.

The HORLEY MOTOR COMPANY show a new two-seated petrol car, of which, in view of its extremely low price, a good number are likely to be seen on the roads in a short time. In general arrangement it follows the usual lines of cardan-shaft driven cars; the motive power is supplied by an 8-h.p. M.M.C. motor, with mechanically-actuated inlet valves. Three speeds forward and a reverse are controlled by one lever, and 3½-in. pneumatic tyres are fitted to the artillery type road wheels. The body is trimmed in real leather, and painted in cream, with fine red lines. Ample space is available at the rear for luggage, or a detachable tonneau can be fitted.

MESSRS. C. S. ROLLS AND CO. have a large stand devoted to a display of various types of Panhard cars, the body work of which is of special interest. The details of the 1904 Panhard cars have already been dealt with in the *Journal*, so that it will suffice to mention that the vehicles exhibited include examples of the 7-n.h.p. two-cylinder, the 8-n.h.p. three-cylinder, the 10-n.h.p., 15-n.h.p., and 24-n.h.p. four-cylinder. The largest size has steel cylinders with corrugated brass water jackets. Ignition is by means of a chain-driven high tension magneto on the dashboard. The wood and steel frame is retained, as well as the Krebs automatic carburettor. A ribbed radiator, set in a frame which forms the water tank, is employed, a fan being provided to induce the necessary current of cool air through the same. The 24-n.h.p. car is fitted with a side-entrance tonneau body, with seating accommodation at the rear for three persons. The 8-n.h.p. has well-upholstered landaulette body, and is designed to serve not only as a long-distance car, but to be equally as suitable for town use as regards quiet running as an electrical vehicle. On the 15-n.h.p. *chassis* is mounted a double phaeton side-entrance body, both seats of which are covered by a hood. The front seats are in addition fitted with a storm apron extending to the top of the hood, and having two celluloid windows. The 7-n.h.p. car has a single landaulet body, the feature being that the steering wheel and control levers are in the interior, thus providing an entirely covered vehicle for those motorists who wish to drive themselves.

E

Digitized by Google

The "GERMAIN" cars are displayed by CAPT. THEO. MASUI, principal interest being centred on the *chassis* of the Germain Standard 16-h.p. four-cylinder car, which is noticeable for its extreme quietness in operation. The four cylinders (Fig. 11) are separate and are each made from a solid bar of steel. The water-jackets are of brass. The inlet and exhaust valves are interchangeable, and actuated mechanically off the same cam shaft. The inlet valves are provided with a device, controlled from the steering wheel, by means of which the lift of the same can be varied, and consequently the speed of the motor regulated. Both battery and Eisemann high-tension magneto ignition are fitted, one advance and retard

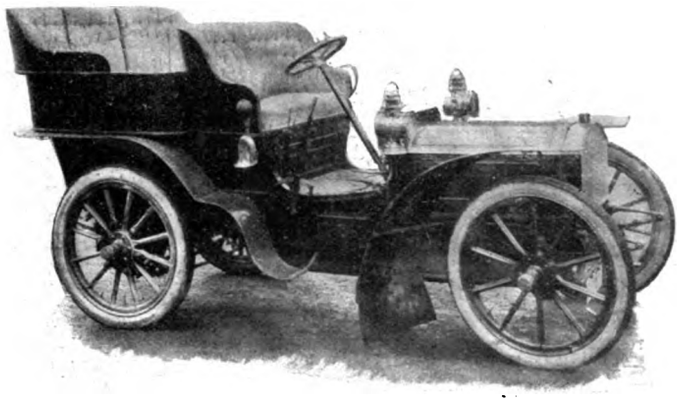

Fig. 10.—The Germain Standard 16 h.p. Car.

lever controlling both systems. The radiator is of the honeycomb type, the arms of the fly-wheel being formed to act as a fan to draw a current of air through the radiating tubes. Three point suspension has been adopted for the change speed gear box, which provides four forward speeds and reverse, controlled by one lever. The *chassis* can be fitted with any type of carriage body. On the stand is shown a most luxurious "tonneau royal" fitted with a detachable brougham top. Mr. Masui also makes a large display of the Samson non-skidding unpuncturable bands for pneumatic tyres.

For the 1904 season the SWIFT MOTOR COMPANY, LTD., have brought out two new models which, while following the standard lines of gear-driven vehicles, bear evidence not only of careful design, but of sound construction. We first examined a 9-11 h.p. car with wood and steel frame (Fig. 12). The engine is an Aster two-cylinder with mechanically-operated inlet valves. The latest type of Longuemare automatic carburettor is fitted, while the car is gear driven, three speeds and a reverse being available. Provision is made in connection with the change-gear lever that the latter cannot accidentally be dropped into the reverse motion notch in the sector. The motor is provided with a governor acting on the inlet, a pedal accelerator being also provided. In addition to a tonneau, this type of *chassis* is also being furnished with a side-entrance double phaeton or landaulette body. The Swift Company are also building a 7-h.p. car which has a tubular frame, in the fore part of which is set a single cylinder engine, 95 mm. bore by 110 mm. stroke, and running at a normal speed of about 1,700 revolutions per minute. The motor has internal flywheels, and is cooled by means of a gear-driven pump, the water circulating through a combined tank and frame and ribbed-pipe radiator. On the outer end of the crank shaft is mounted a drum, which forms part of a conical clutch, transmitting the power to the gear box, which is adapted to give three speeds and reverse with direct drive on the top speed. From the gear box the power is conveyed through a cardan shaft and bevel gearing to a rear live axle, which runs on four ball

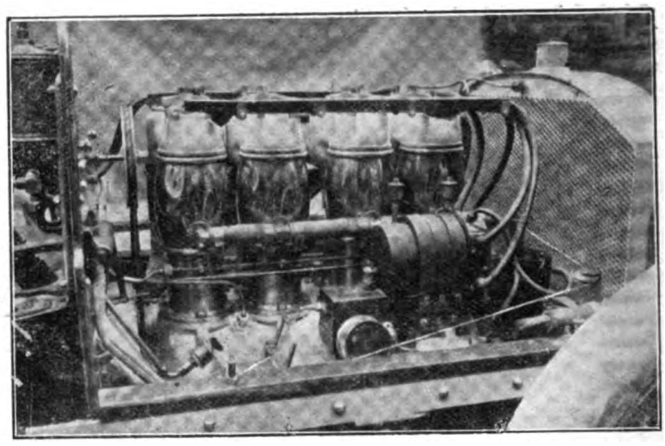

Fig. 11.—The Germain Steel Cylinder Motor.

bearings, and is well supported by tie rods. The foot brake is of the metal to metal type mounted on the rear end of the gear shaft, while the hand brake acts on drums connected with the rear wheels. The speed of the engine is controlled by a lever acting on the exhaust valve. The tubular frame is carried on four long and flexible springs, and it is also worthy of note that the fore part of the body is independently mounted on four cushion springs, which eliminate all vibration at the footboard. The steering is of the irreversible worm and segment type. Altogether the new 7-h.p. Swift is an excellent production, and should prove as successful as its forerunner. Examples of the Swift 3½-h.p. belt-driven and 2¾-h.p. two-speed worm-gear driven motor-bicycles are also to be seen at this stand.

In the Minor Hall the CADOGAN GARAGE AND MOTOR COMPANY, LIMITED, display a new petrol lorry of Belgian construction, of which an illustration was given in a recent issue of the *Journal*. It is designed to carry a load of 5 tons and capable of hauling a further 3 tons on a trailer. The frame of the vehicle is of channel steel. The motor, which is located in the fore part of the *chassis*, is of the Gobron-Brillié type, having two cylinders and four pistons; it is stated to develop 34 brake h.p. Four speeds forward and reverse are provided, the quadrant on which the change speed lever works having a neutral stop between each notch or gear, so that the latter can be put in the free position at any point. From the gear box the power is transmitted by side chains. The tare weight of the

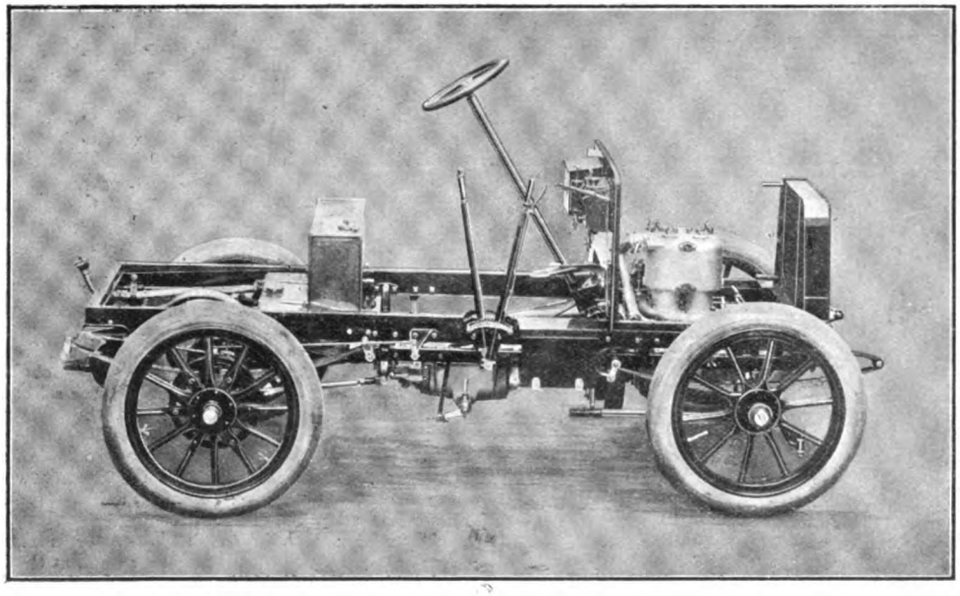

Fig. 12.—Chassis of 9-11-h.p. Swift Car.

Digitized by Google

wagon is under 2½ tons, and with its full load it can attain a speed of 10 miles per hour. One of its features is the low consumption of fuel—it being claimed to carry 5 tons a distance of 5 miles on one gallon of ·74 petrol, the cost of which is said to be 7½d. per gallon.

While the well-known two-seated Baby Peugeot is still being turned out in large numbers, it has now got a younger but more powerful brother in the shape of Baby Peugeot No. 2. Both are to be seen at the stand of Messrs. Friswell, Limited. The No. 1 Baby is now too well known to need lengthy description, but among the many minor improvements we note that the rear axle is now being made stronger, and that adjustable ball bearings are fitted in the centre, outside the differential gear box. The wheel base has also been slightly lengthened. A new three-speed and reverse gear is now employed, ball bearings being fitted to the second shaft. An interesting little detail is that the oiler is now arranged so that it can be actuated by the foot. With a hood, side doors, and front glass, the Baby makes a decidedly smart little car, one of which on the stand is, we may mention, fitted with solid rubber tyres. For those who require a rather more powerful car the No. 2 Baby (Fig. 13) has been introduced. This has a tubular frame, in the fore part of which is set a 6½-h.p. vertical single-cylinder engine. The water cooling is maintained by a friction-driven pump and combined honeycomb radiator and water tank. The usual high-tension ignition is adopted, the contact maker being driven by bevel gear off the cam shaft and located in a very convenient position. The internal leather-faced clutch is also provided with an easy means of adjustment. Three speeds forward and a reverse are provided by a gear box of the usual type; we notice, however, that the lay shaft runs on ball bearings. From the gear box the power is transmitted by a cardan shaft and steel bevel gear to a live axle. A special form of silencer is fitted, which renders the car very quiet in operation. The artillery type road wheels are shod with 3 in. pneumatic tyres. The body comprises two bucket seats upholstered in real leather. Ample space is provided at the rear to carry tools and luggage. The largest car on Messrs. Friswell's stand is a 15-h.p. Peugeot with four-cylinder motor, the cylinders of which

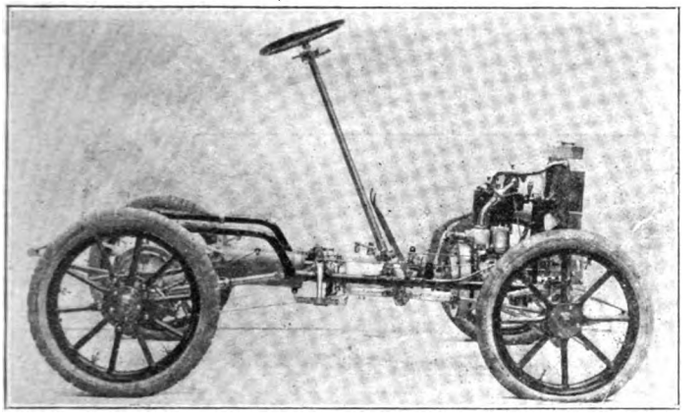

Fig. 13.—Chassis of Baby Peugeot No. 2.

are cast in two pairs; the inlet valves are mechanically actuated, and the carburettor, which is of the automatic variety, has a jacket through which hot water can be circulated as desired. The governor acts not only on the admission, controlling the amount of mixture passing to the engine, but as the supply is cut down the air inlet is varied. Both high-tension and magneto ignition, controlled by one lever on the steering wheel are provided. The flywheel is of larger diameter than last year, being now 18 in.; the clutch is so arranged that it can be dismounted without disturbing the gear box. The latter, which provides four speeds forward and one reverse, is of novel design, in that the usual lubricators connected with the bearings are conspicuous by their absence, they receiving their oil from the mechanical lubricator on the dash-board. The gear box is made in two halves, and in the planed faces of the lower one a channel is formed to which oil is fed by means of two pipes. The oil then finds its way to the different bearings, which are provided with chain oilers as used on dynamos, and finally falls into the gear box. From the latter the power is conveyed to the rear road wheels by means of side chains. The frame is of pressed steel with long springs, the car, with tonneau body, having the appearance of being both speedy and comfortable.

The Fiat cars, shown by Fiat Motors, Limited, are of Italian construction. They take a very high place in modern automobiles, and in many respects are closely allied to the Mercedes; they possess many features of their own, however, among which may be mentioned the automatic advance and retard of the magneto ignition, this being provided with its own centrifugal governor. Needless to say, the frame is of pressed steel, and the engine is of the four-cylinder type. The 16–21-h.p. type has cylinders 110 mm. in diameter by 110 mm. bore, the normal speed being 800 to 1,000 revolutions. The engine speed can, however, be varied from 150 to 1,800 revolutions. The carburettor is of the automatic variety, regulating both the supply of air and petrol by means of a needle valve and plunger, acted upon both by the governor and from the steering wheel. The clutch is of the coil type, while the transmission is by side chains. A special point is the lubrication, all bearings being oiled from the dashboard. The oil is contained in a reservoir in which is a spindle driven by the engine through a belt and worm gear. To the spindle are provided a number of very small buckets, which, as they rotate, pick up a certain amount of oil, which is emptied into its corresponding pipe. There are many other points of interest in the Fiat cars, of which a handsome 16-h.p. side-entrance

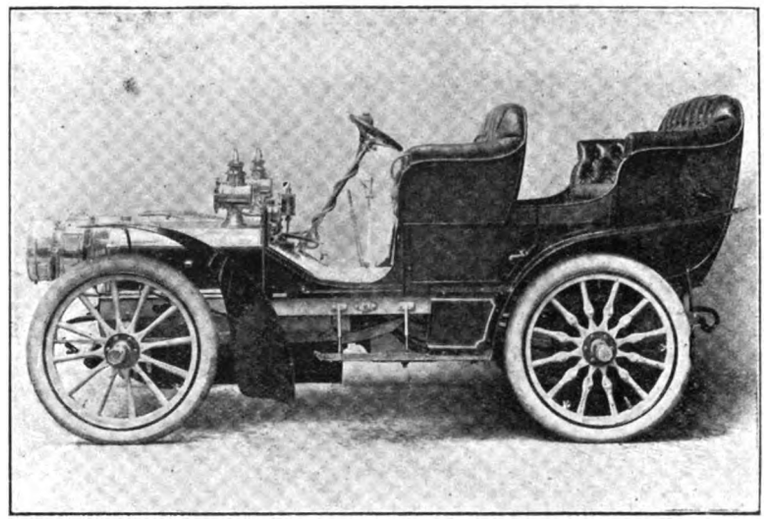

Fig. 14.—A Fiat 16–21-h.p. Car with Shrewsbury Phaeton Body.

double phaeton (Fig. 14), one with a tonneau, and one with a landaulette body are being displayed.

The Maudslay Motor Company's exhibit consists of three complete cars and a *chassis*. One of the vehicles is fitted with a convertible omnibus body, designed to meet the requirements of country gentlemen whose places are some distance from the railway; in its wagonette form it serves as a roomy touring car, whilst the omnibus top makes it specially suitable for night work. It is fitted with the Maudslay 25-b.h.p. three-cylinder vertical balanced engine. The second car is fitted with a double phaeton side-entrance body. The mechanism is similar to the 25-b.h.p. car, but the engine is of 18-b.h.p. Removable casings of sheet aluminium are fitted, which completely protect the whole of the mechanism from mud and dust below the car, this being now a standard fitting on all the Maudslay cars. The third vehicle is an 18-h.p. double phaeton with brougham top. A *chassis* to illustrate the new features of the 1904 type is also staged, which embodies the latest developments in English and Continental practice. The inlet valves of the motor are mechanically actuated, and both inlet and exhaust valves are placed in line on the cylinder head, so that they are easy of access. A fan-cooled radiator is fitted, and forced lubrication is provided throughout, the oil being circulated by a special design of geared pump. We notice that the composite frame, constructed of rectangular solid drawn steel tube, into which ash is driven, is retained in the 1904 patterns. The triple cylinders of the engine, together with their combustion chambers,

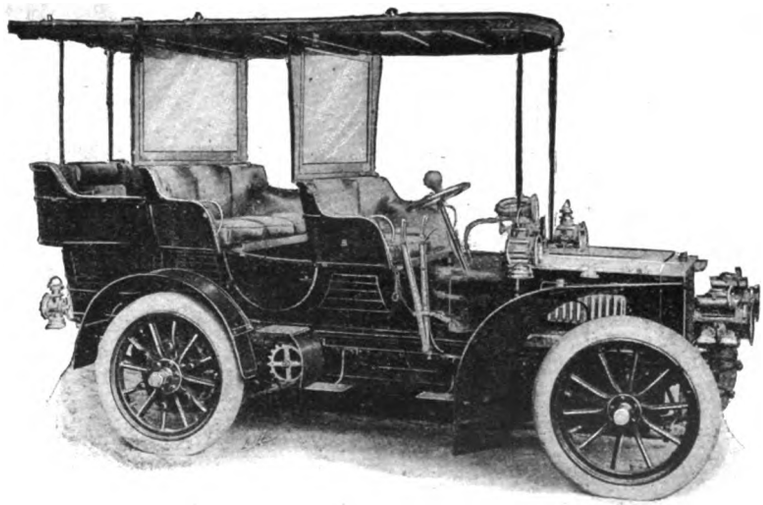

Fig. 15.—The Maudslay Eight-Seated Touring Car.

are a single casting, ensuring freedom from leaky joints, and allowing the use of a high compression. With the foregoing exceptions, the details of the car are similar to those described in these columns early last year, they having been found to give satisfactory results in practice. The Maudslay Company are now devoting attention to marine motors, and have on view a large three-cylinder engine fitted with propeller shaft, etc.

Digitized by Google

The WESTON MOTOR SYNDICATE are again well to the front with a display of the Chenard-Walcker cars, the main features of which have already been fully dealt with in the *Journal*. It may, however, be briefly that two types are being made—18-h.p. and 12-h.p. The 18-h.p. cars have four-cylinder engines with mechanically-operated inlet valves located on the opposite side to the exhaust valves; the characteristic point of the

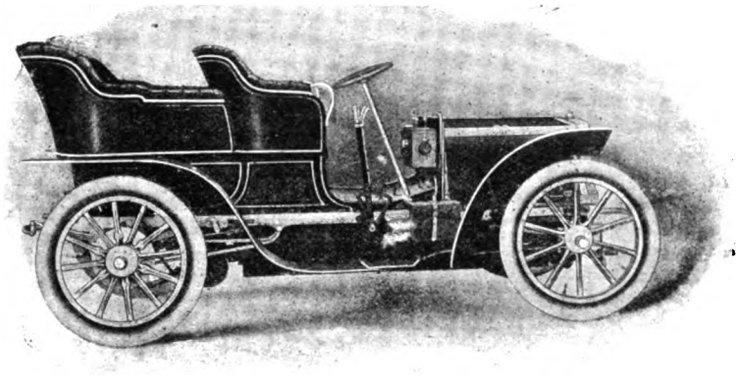

Fig. 16.—The Chenard-Walcker 18-h.p. Car.

motor is, of course, the peculiarly-shaped cam, by means of which not the lift, but the duration of the time the inlet valves are kept fully open, can be varied, and the speed of the engine consequently controlled. The automatic carburettor which furnishes a quality of mixture to correspond to the engine speed was illustrated and described in a recent issue; it comprises a compound valve, part of which regulates the supply of air and the other portion the supply of petrol. The water-circulation pump has been discarded in the 1904 Chenard-Walcker, the thermo-syphon system in conjunction with a special honeycomb radiator being relied upon. Magneto or high-tension ignition, with a chain-driven commutator on the dash board, can be fitted. The special combined clutch and brake is still retained, as is also the Chenard-Walcker transmission, in which, it may be remembered, the power is transmitted through a cardan shaft to a differential shaft below and parallel with the rear axle. On the ends of the differential shaft are pinions meshing with internally-toothed rings attached to the rear road wheels. The governor can be set to act at any desired speed from the steering wheel, a pedal accelerator cutting out the governor, no matter at what point this is set to act. The Chenard-Walcker has a record for economy in fuel consumption, while the special control results in an exceedingly silent-running and flexible engine. The 12-h.p Chenard-Walcker car has a two-cylinder motor; it is provided with the special valve control found on the 18-h.p. car; an ordinary type of carburettor is used. The transmission is by means of side chains, three speeds forward and reverse being provided, the drive on the top speed being direct. As regards complete cars, attention may be drawn to an 18-h.p. tonneau with entrance at the side, and adapted to be fitted with a detachable brougham top, and to a 12-h.p. touring car with tonneau body, with canopy, side curtains and front glass screen.

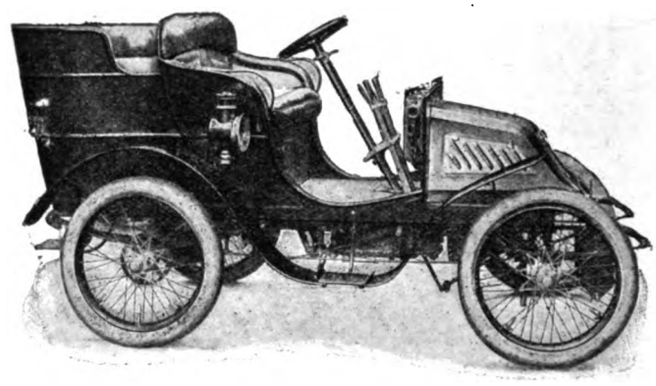

Fig. 17.—The British Peerless 8-h.p. Car.

The exhibit of the BRITISH PEERLESS MOTOR COMPANY comprises a "British Peerless" *chassis* and a complete tonneau car. These, as the name implies, are of English construction. The frame is of tubular construction, in the fore part of which is set an 8-h.p. single cylinder vertical motor. The cylinder is 4½-in. diameter by 4½-in. stroke. A feature of the engine is that the crank case and girder supports, the latter being equal to the full width of the frame, are made in one piece. The pump is so made that it can quickly be detached, while a throttle valve is provided. Three speeds and a reverse are available by the usual type of sliding gears, controlled by one lever. From the gear box the power is transmitted by universally-jointed shaft and bevel gearing; a flexible joint is also fitted between the clutch and gear box. The steering is by wheel, worm, and segment. A foot brake is provided, and in addition an emergency brake is fitted at either end of the back axle, controlled through

Fig. 18.—The Beaufort 15-20-h.p. Beaufort Princess Car. (*See page 77*).

Digitized by Google

qualising gear, from a lever at the driver's right hand. A 10-h.p. car is also being made by this concern: this has a two-cylinder engine, 3¾-in. bore by 4½-in. stroke, the inlet valves being mechanically actuated. Ignition is by chain-driven Eisemann high-tension magneto. The transmission is by

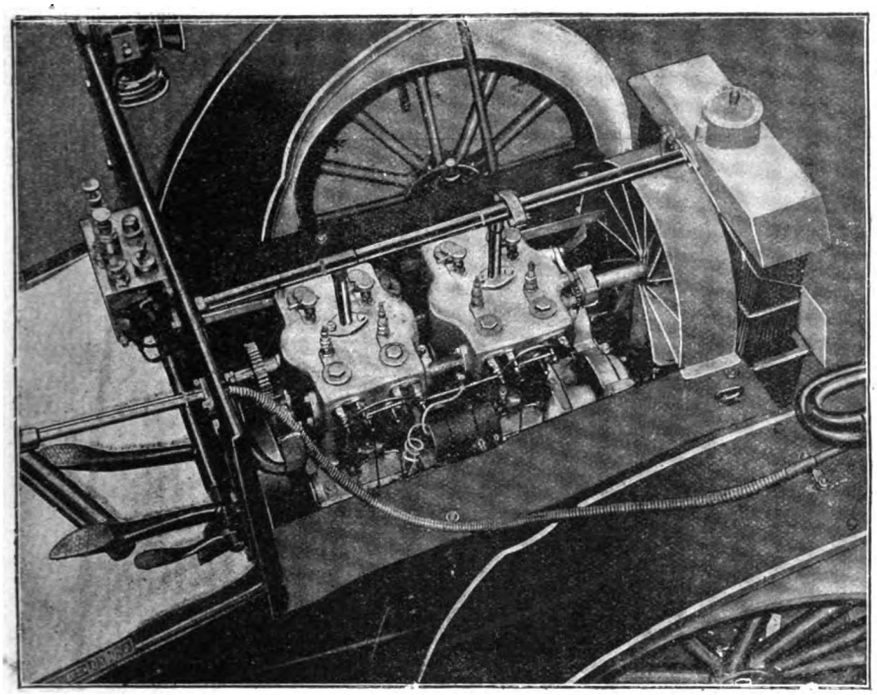

Fig. 19.—The Beaufort 24-h.p. Four-Cylinder Engine.

cardan shaft and bevel gear on to a live axle. Three forward speeds and a reverse with direct drive on top speed are provided. The brakes on this car are worthy of special attention, the bands of those on the rear wheel hubs being lined with blocks of poplar wood, fixed in a dovetail groove, and which, while having great holding power, are claimed to be not liable to fire.

An excellent display of the popular "Beaufort" cars is made by the Beaufort Motor Company; for the 1904 season these vehicles are being made in five sizes, ranging from 9-h.p. to 24-30-h.p. The latter is a new model; it is a chain-driven vehicle, having a pressed steel frame and four-cylinder motor, the cylinders being 110 mm. diameter by 125 mm. stroke. The valves are all mechanically-actuated; while two ignitions, the Bergmann magneto and the high-tension system by coil and accumulators, are provided, both being advanced and retarded by one lever. A small four-way switch is mounted on the dashboard, by means of which the two systems may be used together, or each separately, and all interrupted. Four speeds forward and a reverse are provided, while the driving wheels are shod with 920 mm. tyres. The other cars are of the cardan-shaft driven type, with live axle running in a sleeve extending the whole of its length. The 9-h.p. has a single-cylinder motor, the 10-h.p. and 12-h.p. two, and the 15-20-h.p. four cylinders; all have gear-driven magneto and three speeds, in addition to the reverse. The larger cars are fitted with a governor, which, in addition to controlling a throttle valve on the admission pipe, allows, when the latter is closed, fresh air to be drawn into the cylinders. The quality of the mixture can also be regulated by means of an adjustable cap on an air inlet on the dashboard leading to the carburettor. The brakes are of the internal expanding type; while on the 15-20-h.p. car, which is fitted with the "Princess" side entrance double phaeton body (Fig 18), we noticed that the steering pivots are now mounted within the hubs of the front road wheels. On the stand are also to be seen examples of the Beaufort 9-h.p. single-cylinder cars, which are so well known as to render a description unnecessary at this time, although special attention may be drawn to one vehicle of this type, which is specially designed for doctors' use, having a hood and front glass screen.

The new models of the Georges Richard Company, shown by Messrs. Mann and Overton's, Ltd., comprise quite a number of special features. For the 1904 season, 8, 12, 16, and 24-h.p. cars will be available. Two-cylinder engines are fitted to the 8-h.p. and 12-h.p., while those of the 16 and 24-h.p. have four cylinders (Fig. 20). Except that the 8-h.p. car has only three speeds forward in addition to the reverse, while the others have four, the following remarks apply to all four vehicles. The main frame is of stamped steel, the engine and gear being supported on a secondary frame of tubular construction. The cylinders, which are cast in pairs, have mechanically operated inlet valves, these being set on the opposite side to the exhaust valves. Magneto ignition is being retained, but the Georges Richard Company have struck out a new line in deciding to abolish the pump, relying on the thermo-siphon action in conjunction with a fan-cooled radiator for the water circulation. The carburettor is an automatic air-regulation one of the Georges Richard Company's own patent. The transmission is by means of a cardan shaft and bevel gear on to a live axle, a new point being the introduction of a universal joint between the engine and gear box, this not only relieving the shafts of the latter of all strain, but permitting the clutch to be dismounted without interfering with the gear box in any way. With the object of rendering the cars quieter than ever, and also of keeping down the dust, a new form of silencer is being adopted; it is of large size and is placed transversely across the rear of the car, the burnt gases finally emerging through two flattened pipes projecting at an angle to the silencer. Enclosed internally-expanding brakes are now fitted, while a new point which will appeal to all who have suffered from "back kicks" of the motor, owing to the ignition not having been retarded, is an arrangement whereby the act of putting the starting handle into gear at the same time automatically retards the ignition; the moment the handle is released the ignition returns to its normal position. The 12-h.p. and 16-h.p. *chassis* are of sufficient length to take bodies with side entrance, while the 24-h.p. type is made with *chassis* of two different lengths. The *clou* of the stand is the identical 24-h.p. Georges Richard car which last week established a new record by running a distance of over 1,000 miles without a stop, and of which an illustration is given on another page of the present issue.

The Vousemoi Company have on view a new two-seated car of 10-h.p. The frame is built up of steel and wood and carries in the fore part a vertical two-cylinder Gnome engine, the cylinders being 98 mm. bore by 130 mm. stroke, and the normal speed 750 revolutions per minute. The inlet valves are mechanically actuated, and a governor acting on the admission is provided. Three speeds forward and a reverse are provided by a gear box of the usual type, the power being transmitted to the rear live axle by a cardan shaft and bevel gear. A pedal operates a band brake on a drum fixed to the gear shaft, and a side hand lever operates equalised band brakes on the rear road wheels; both brakes act equally well in each direction. The car, which has a wheel base of 6 feet 10 inches, is provided with two large bucket seats, and fitted at the back with a large sloping box with compartments for tools and luggage;

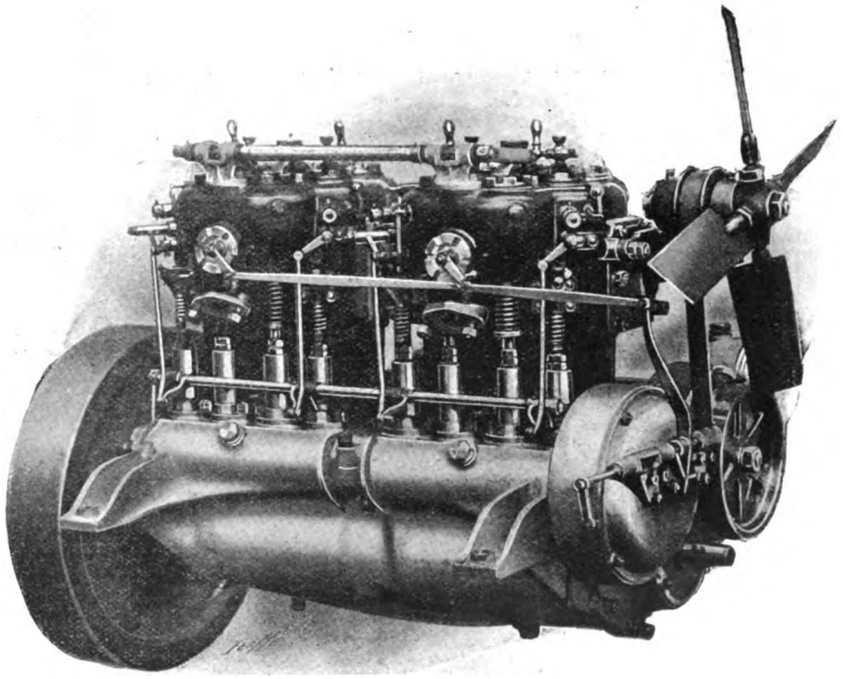

Fig. 20.—The Georges Richard Four-Cylinder Engine.

it can also be fitted with a four-seated body. The speed of the engine is controlled by the ignition as well as by a throttle valve, permitting, with the change gear, speeds from 3 to 35 miles per hour to be attained.

Digitized by Google

The stand of the STAR MOTOR COMPANY is attracting much attention, the cause being the *chassis* of the new 7-h.p. double-cylinder two-seated Star car. In view of its relative low price, the new vehicle is likely to become very popular. The frame is of the usual wood and steel type and the general arrangement follows that usually adopted in chain-driven cars. The engine has cylinders 3½ in. bore by 4½ in. stroke. The cam shaft is outside the crank case, and a new feature is the fitting of a guide piece and double springs to the exhaust valves. Three speeds forward and a reverse are available, the drive on the top speed being direct through the clutch, differential shaft and side chains. One of the "Little Star" 6-h.p. two-seated cars, which has already been illustrated in the *Journal*, is also on view. It is fitted with a single-cylinder engine, and at its reduced price is excellent value. On the stand are also examples of the Star Company's 18-h.p. and 12-h.p. cars. The first-named vehicle is well worthy of examination; it is fitted with a vertical four-cylinder engine of 18-h.p., the inlet as well as the exhaust valves being mechanically actuated. Four speeds forward and a reverse on one lever are available, the chain system of transmission from the differential countershaft being adopted. A large silencer is fitted, rendering the car very quiet in operation. We notice that the side chains of this vehicle are provided with oil-containing gear cases. The body is of high-class finish, the *chassis* having a long wheel base, enabling one with side entrance to the rear seats to be fitted.

MR. MORGAN DONNE, the British agent for the Rochet-Schneider vehicles, exhibits an excellent example of the 16-22-h.p. car of this type. The vehicle (Fig. 22), has a wheel base of 8 ft. 6½ in., the *chassis* weighing 650 kilos. The frame is of pressed steel, and is narrowed in front to increase the "lock" of the steering wheels. The steering rod connecting the front wheels is behind the front axle and consequently protected from accident. The clutch and brake pedals, which are of the "push" type, are mounted upon a transverse shaft underneath the footboard, which actuates the clutch, and also the countershaft brakes. Although there is no radical alteration in the engine as compared with that of last year, there are a number of improvements; it is of the double twin cylinder type, having the inlet valves, sparking tappets, and the vertical rods and levers for actuating the same on one side of the engine and the exhaust valves on the opposite side, the inlet and exhaust valves being interchangeable and mechanically operated. The ignition is by a low-speed rotary magneto with tappets and advance sparking device. The governor acts directly on the carburettor; a throttle lever is also fitted on the steering wheel, while adjacent to the wheel are two levers, one for regulating the air to the carburettor and the other for the advance sparking. Four speeds and reverse, with direct drive on the fourth, are provided. The top shaft in the gear-box, which is square in section and connected with the clutch, has mounted upon it the sliding gears; the latter are in two portions, and are operated upon by two forks, one of which controls two speeds and the other two speeds and reverse. These forks are actuated by means of a locking bar, which has several projections and recesses to give the desired motion necessary for placing the various gears in and out of mesh. The male portion of the clutch is connected to the gear by means of a cardan joint (Fig. 23), which counteracts any undue strain on the gear-box and engine; the joint also permits of the male portion of the clutch finding its true position in the flywheel. Any type of carriage body can, of course, be fitted to the *chassis*. A handsome 24-30-h.p. car on similar lines is also on view.

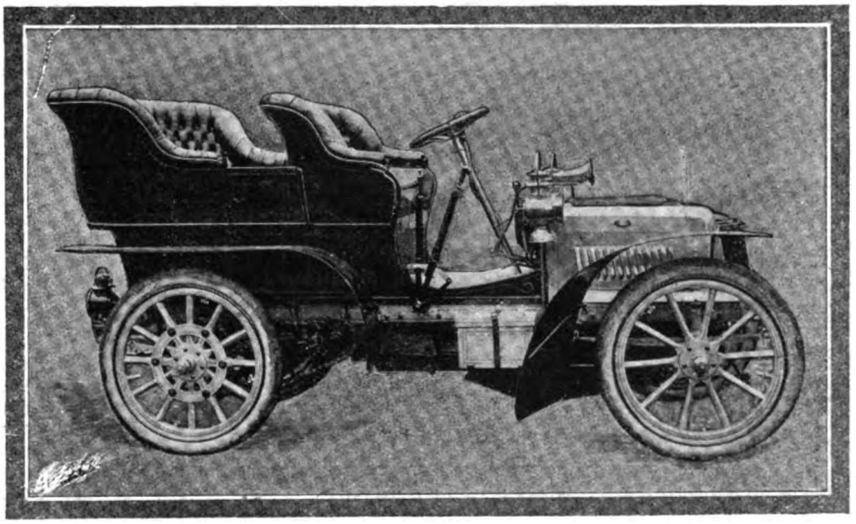

Fig. 21.—The Star 18-h.p. Four-cylinder Car.

The LANCASTER MOTOR GARAGE have a large display of cars, including a 6-h.p. De Dion Populaire and several 8 and 10-h.p. Panhards, the latter including a neat landaulette with the engine under the driver's seat, and a 10-h.p. tonneau with Cape cart hood and storm apron, in which is fixed a large transparent panel of celluloid. Chief interest at this stand, however, lies in the *chassis* of the Mass 12-h.p. car. This is a French production, and contains a number of novel features. The motor is a two-cylinder 12-h.p. De Dion engine with automatic valves, set in the fore part of a pressed steel frame, the cylinders being 100 mm. bore by 110 mm. stroke, and the normal speed 1,500 revolutions per minute. It is fitted with two carburettors, one to each cylinder, and with automatic lubrication, operated by a pump forcing the oil from the crank chamber to a reservoir placed on the left-hand side of the engine, whence the oil drips by gravity on to the crank shaft. The engine is controlled by a foot throttle or moderator pedal, by means of which the car can be driven at a crawling pace on the top speed. The clutch is of novel type, giving a metal-to-metal contact and an easy and gentle action, so that it is claimed to be possible to drive in traffic on top speed. As will be seen from Figs. 24-25, the male portion of the clutch consists of four bronze shoes pressed outwardly against the inner surface of the flywheel by spiral springs. These shoes can be withdrawn from contact with the flywheel by depressing the clutch

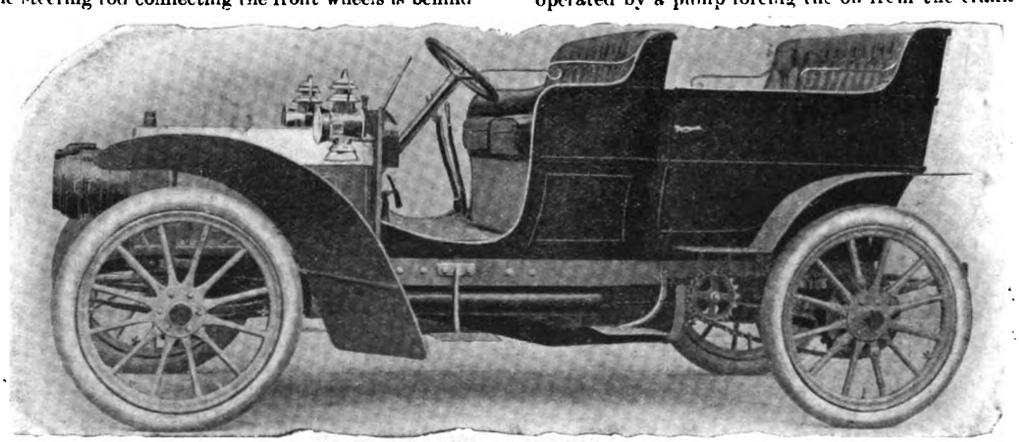

Fig. 22.—The 16-22-h.p. Rochet-Schneider Car.

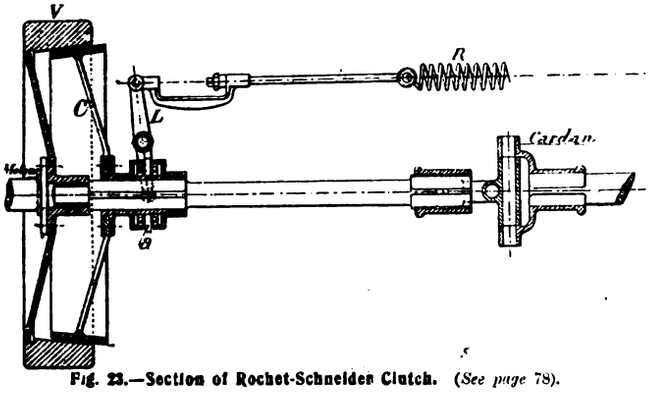
Digitized by Google

pedal through the intervention of the bell crank levers. It will be noticed that the movement of the shoes is a radial one, and that centrifugal force acts on them in a direction tending to increase the pressure between their surfaces and the inner surface of the flywheel. The drive is from the clutch by a long propeller shaft to the change speed box, which is attached directly to the casting enclosing the bevel and differential on the live axle. From this disposition of the gear box the clutch can be taken out by merely disconnecting one joint of the cardan shaft. The change-speed gear is of the sliding pinion type, giving three speeds forward and a reverse on the same lever, the top speed being a direct drive. The pinions are made of manganese silicious steel, and the teeth are nearly an inch in



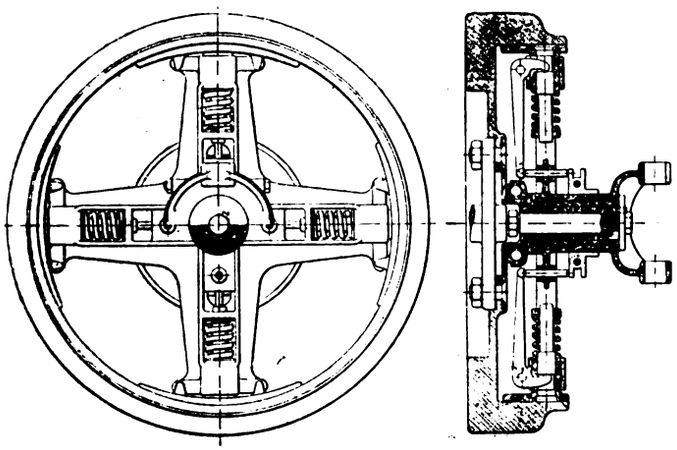


Fig. 23.—Section of Rochet-Schneider Clutch. (See page 78).

breadth. The nickel steel shafts on which they are mounted are approximately 1½ in. in diameter. The shafts carrying the pinions in the gear box are also very short. In fact, the length of the gear box, measured from bearing to bearing, is only 4¼ in. It has been continually urged as a defect in cars with a live axle that the rotating portions of the axle are subject to all the strains set up by the unevenness of the road. In the Mass car this difficulty is got over in a simple and effective manner. In effect, the car has two back axles, one of which supports the car and the other transmits the drive, so that no shock can possibly be transmitted to the running parts. Among so many novel features it is invidious to select one as particularly original, but there is no doubt that the method of lubricating the gear box, bevel and differential, is as novel as it is simple and effective. The bevel acts as a pump; it picks up oil from the bottom of the bevel case and projects it into a cavity situated at the top of the bevel casing, as shown in Fig. 26. From here the oil flows along a passage bored in the axis of one of the bolts connecting the gear box to the bevel case, whence it falls under the action of gravity into the bearings of the change-speed gear. From these it drips into the bottom of the change-speed box, and thus lubricates the teeth of the change-speed pinions, and returns by a similar passage bored in one of the lower bolts serving to attach the change-speed box to the bevel case, to the latter, thus having completed its circuit. In this way a forced lubrication is provided to both the bevel gear and differential, without the intervention of a pump.

Figs. 24 and 25.—Front and Sectional View of Clutch on 'Mass' Car.

Ball bearings are fitted to the thrust of the differential and the hubs of the back wheels; all other bearings are of phosphor bronze. Another point to which attention may be directed is the accessibility and detachability of the various parts. For instance, to take down a cardan joint it is only necessary to remove one bolt. To take out the internal member of the clutch, only one nut has to be removed; while to get the gear box as a whole out of the car, six bolts in all have to be detached. Both the foot and hand brakes act on drums on the rear wheels, one contracting and the other expanding in the same drum. Altogether, the new Mass car is an interesting production.

The feature of the stand of the ELSWORTH AUTOMOBILE COMPANY is a Spyker *chassis* (Fig. 28) of what is known as the 1905 model. The 12-16-h.p. engine on this car resembles more than anything else a dynamo at first sight. Two cylinders and their valve chambers are cast in one with a large circular water jacket which surrounds the whole. The two castings to form the four-cylinder engine have faces which fit closely together, and are kept in position by bolts. A large body of water—about 1½ gallon—is always maintained around the cylinders, this being circulated in the usual way by pump and fan-cooled radiator. The frame of the Spyker cars is of a special pressed steel shape, filled with ash. The *chassis* are adapted to take all types of carriage bodies, including those with side entrance. The cars follow the usual lines of cardan-shaft transmission vehicles, among the features being the ready means of access to the pinions in the gear box,

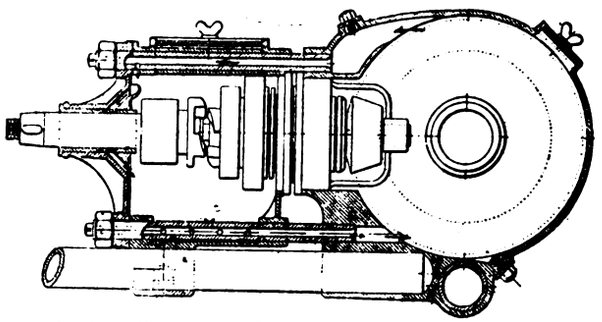

Fig. .—Sectional View of Gear Box and Differential Gear on "Mass" Car, howing Special Lubricating System.

and the pivots of the front wheels, which are entirely enclosed, and work in an oil bath. A 20-24-h.p. Spyker car, with highly-finished limousine body, and with the usual type of four-cylinder vertical engine (Fig. 27) is also displayed.

In addition to a complete Siddeley 6-h.p. light car and a *chassis* of the same (of which an illustrated description was given in our issue of the 20th February last), the SIDDELEY AUTOCAR COMPANY have on view examples of their new types of 12-h.p. and 18-h.p. cars built to their specification by the Wolseley Tool and Motor-Car Company, Limited. The 12-h.p. car has a two-cylinder motor, with cylinders of 4½ in. by 4½ in., while the 18-h.p. car (Fig. 29) has four cylinders, 4 in. bore and 4 in. stroke. With the exception of the engines, the main features of each of these vehicles are identical, so that the following particulars may be taken as applying to

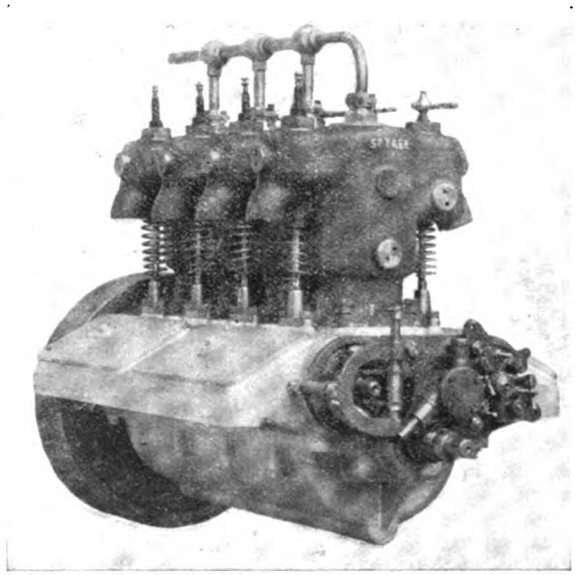

Fig. 27.—The Spyker Four-Cylinder Vertical Motor.

both. The frame is of pressed steel, strongly braced at intervals and strengthened by plate webs at the angles. The motor is located in the front of this, under a bonnet in the usual way. The cylinder jackets are of aluminium, and are cast in one piece with the top half of the base chamber, cast-iron liners for the cylinders being forced into the aluminium casing. The top of the cylinders and valve pockets are a separate casting bolted on. Ample spaces have been provided for the water circulation, and the jackets of the head and cylinders are connected by outside pipes, so that there are no water joints in the cylinders proper. Both valves are mechanically operated by a single cam shaft on the left-hand side of the engine. The

Digitized by Google

inlet valves are located directly over the exhaust, and actuated by means of vertical rods and tappet levers. The inlet valves are provided with a variable lift device, controlled by means of a small lever on the steering wheel. The water circulation is maintained by a gear-driven pump and a framed ribbed pipe radiator, these being so arranged that but short lengths of piping are required. The carburettor is of the automatic air-positive stop at each speed. The change gear box and the differential are also carried in what is practically one casing. The shafts are on ball bearings throughout and are provided with ball thrusts where required, this applying to the countershaft as well as to the two shafts in the gear box. The teeth of the pinions in the latter are one inch in width, the gear throughout being strong enough to take a much higher power than it will ever be

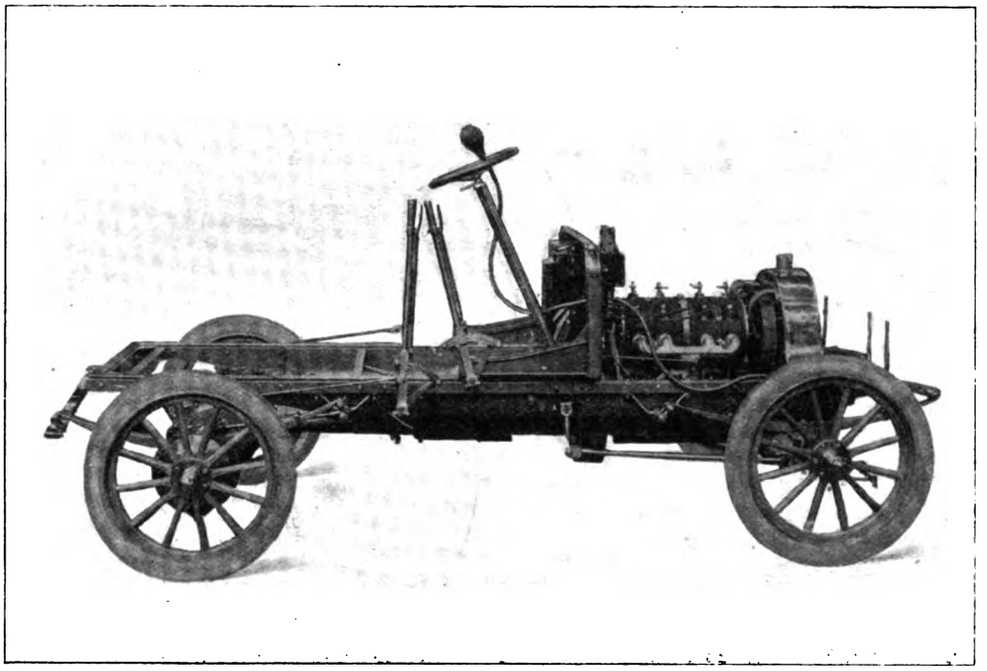

Fig. 28.—Chassis of Spyker 16-h.p. Car. (*See page 79.*)

regulating type, a disc held by a spring being raised as the speed of the engine rises, and thereby admitting a further supply of air in direct proportion to the requirements of the engine. The governor is of the usual form and acts on a throttle of the pierced disc pattern between the carburettor and the motor. It can be put out of action by the usual foot accelerator. The combination of the automatic carburettor and variable lift of the inlet valve results in a very elastic engine, the speed of which can be regulated between 80 to 1,800 revolutions per minute, the normal speed being about called upon to transmit. From the differential shaft to the rear road wheels the power is transmitted by side chains. Both the hand and foot brakes are concentrated on the rear wheels, the pedal brake expanding inside the brake drums, and the side brake being of the ordinary external band type, provision being made for keeping the bands away from the rings when the brakes are out of action. The *chassis* of the 18-h.p. car weighs 14¾ cwt., and has a wheelbase of 7 ft. 10 in. That of the 12-h.p. weighs about 3 cwt. less, and has a 7 ft. 1 in. wheel base. There are many

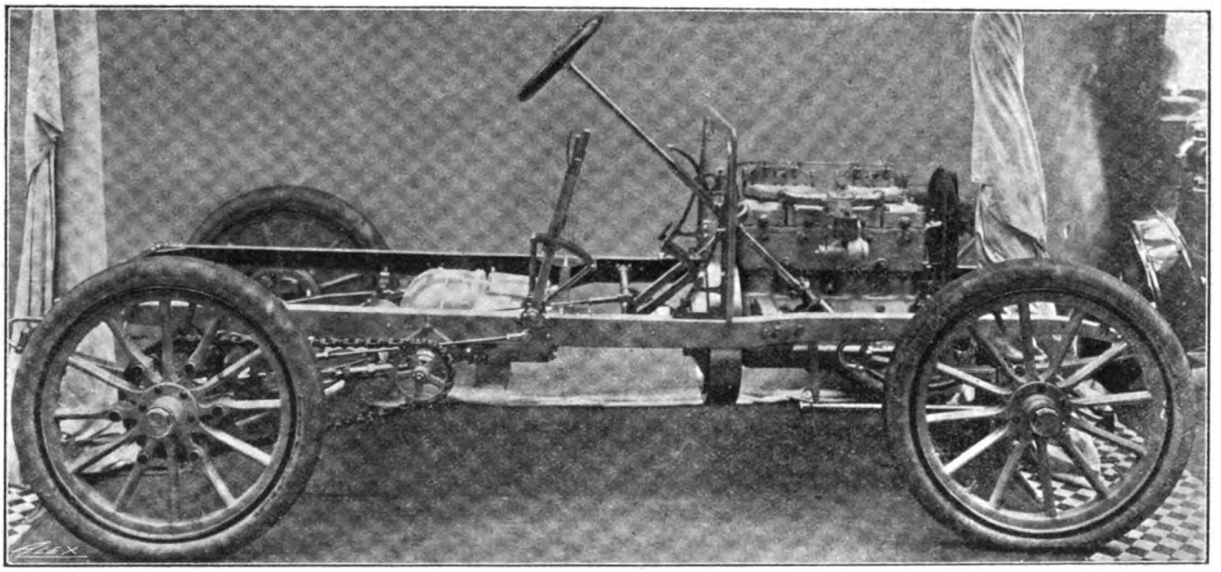

Fig. 29.—Chassis of Siddeley 18-h.p Car. (*See page 79.*)

1,000. Ignition is on the high-tension system, the accumulator being located on the dash-board. Coming to the transmission, the power is conveyed through a large diameter leather-faced clutch. The connection with the primary shaft of the change-speed gear is by a universally-jointed shaft, so arranged that the clutch can be detached without disturbing the gear. Four speeds and one reverse are controlled by one lever, which has a points of interest in the new Siddeley cars which can only be clearly explained by means of drawings, the vehicles throughout bearing evidence of the care which has been taken both as regards design and construction.

The "Ludgate" light runabout—a two-seated car at a low price—is shown by Mr. J. F. Bentley. This is a chain-driven car with a 4-h.p. water-cooled motor and having two speeds.

Digitized by Google

STEAM VEHICLES AND OTHER EXHIBITS.

MANN'S PATENT STEAM CART AND WAGON COMPANY, LIMITED, again display one of their steam vehicles. This is of novel design, and is intended to carry a load of three tons. It is provided with a boiler of the locomotive type, with the fire-box sides carried back to form the engine bed and support the brackets for the necessary shafts and gearing. The same plates also

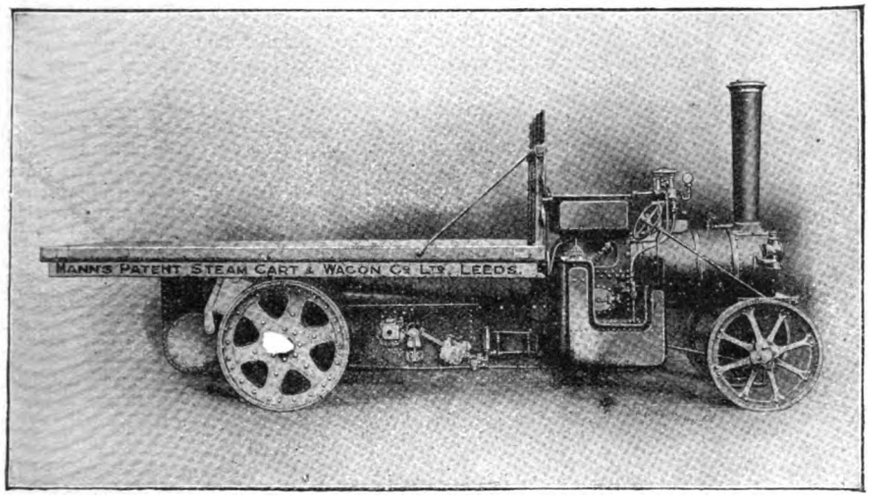

Fig 30.—Mann's Steam Wagon

compose the water tank, and form an exceptionally strong girder frame to carry the whole vehicle. The engine is of the compound type, with single eccentric reversing gear, and the whole runs in a dust-proof oil bath. The gearing is of cast steel throughout, with no chains, either for driving or steering. The road wheels are fitted with an effective arrangement for locking the differential gear on occasion. Two speeds, one of 5 and the other of 2½ miles per hour for hill climbing, are provided. The exhaust steam is passed through a separator, and superheated to prevent the emission of visible vapour, and the boiler is constructed to burn coke for the same reason. In general design and construction the wagons follow traction engine practice. They can be fitted with any class of sides or van bodies to suit individual requirements, or with tipping gear of such construction that one man can readily tip the full load.

MESSRS. FODENS, LIMITED, exhibit two heavy steam vehicles, one being intended for general hauling purposes for loads up to 5 tons, and one with tipping body and 14 in. wide road wheels for municipal purposes (Fig. 31) In general appearance the Foden wagons take the form of a small traction engine, behind which is mounted a platform upon which the load is carried. The boiler, which is of the horizontal multitubular type, forms the front part of the framework. The sides of the frame are constructed of channel steel, tied and braced together in such a manner as to secure great strength in the complete lorry. The boiler can be fired with coke, coal, or wood. The wagon is driven by a compound steam-engine fixed on the top of the boiler The cylinders are 4¼ in. and 6½ in. diameter by 7 in. stroke, and are fitted with high-pressure gear, by means of which both can, in case of emergency, receive live steam from the boiler, and each cylinder exhaust independently into the chimney. The reversing motion is of the ordinary link type. The power is transmitted by spur wheels to the compensating gear shaft, and thence to the rear axle by an extra strong roller chain. The gearing is arranged for two speeds. The vehicle is mounted on laminated springs, with angle axle guards containing the sliding axle boxes, similar to those on the modern railway carriage. During the last twelve months over forty of these wagons have been turned out by Messrs. Foden, who are now arranging for an increased output.

The "Little Giant" steam motors are shown in two forms by MESSRS. W. TASKER AND SONS, LIMITED, one being fitted with a single-acting motor and the other with a compound engine. These are miniature traction engines, designed to haul loads of from five to six tons on trailing wagons. MESSRS. WALLIS AND STEEVENS, LIMITED, exhibit one of their miniature traction engines for hauling loads of from three to six tons. The firm claim to be the pioneers of this type of motor, and now have a large number in use in various parts of the country. They are fitted with enlarged smoke-box, spark-catcher, a patent arrangement for controlling the draught, and an auxiliary valve which enables the engine to be started instantly.

MESSRS. J. AND F. HOWARD make their *debut* at the Agricultura Hall Exhibition with a steam-wagon built to carry a load of 5 tons. As an illustrated description of this vehicle was given in our issue of Feb. 6th last, it is only necessary to mention that it is adapted to burn coke or coal, and that the working pressure is 200 lb. per square inch. It is fitted with a compound engine running in an oil bath. There are two feed pumps, and the regulation of steam is controlled by a foot lever without the driver having to remove his hands from the steering-wheel. Altogether the Howard is an interesting addition to the heavy steam vehicle family.

High-class lubricants for motor-cars are shown by the STERN SONNEBORN OIL COMPANY. Sternol-automotor oil and Sternol valve oil are among the specialities of the company. Vacuum Mobiloils for the lubrication of automobiles are on the stand of the VACUUM OIL COMPANY, whose sight-feed lubricating appliances and Pony Rochester lubricators are well known among motorists. The "G. B." motor requisites are shown by the COUNTY CHEMICAL COMPANY, LIMITED, whose specialities include motor repair outfits, celluloid cements, etc. The company possess their own process for treating motor carbide so as to secure slow decomposition and a high percentage of gas. They have also a petrol intensifier, in connection with which mention may be made of the "G. B." picric funnel for conveying petrol into the tank. It is made of copper, fitted with a fine gauze sieve, below which is a chamber containing enough picric acid for intensifying forty gallons of petrol. Just sufficient acid passes into the petrol to fortify it, whilst the gauze prevents any crystals getting into the tank. The "Sisco" motor oils and greases are making their initial bow at a motor-car exhibition, being shown by Messrs. SISSONS BROTHERS AND CO., LIMITED, in an attractive form. The "Sisco" motor oils are made in two qualities, for air and water-cooled cylinders respectively. These oils are claimed not to clog or carbonise, and ensure smooth and easy running. PATCHO, LIMITED, make a display of their liquid tyre cement for repairing covers and tubes without the aid of rubber or chalk. The "Unicorn" motor oils are being shown by MESSRS. J. FOUIGER AND SONS, who have several varnishes and enamels suitable for motor work. They have also brought out a can which is specially adaptable for pouring thick oils, and this is being shown at their stand in the Berner's Hall.

The "Vortex" tubular radiator, shown by MR. J. RUSSELL, secures a free circulation of water through an uninterrupted cooling surface of tube. The tubes are arranged perpendicularly, a wire with frequent bends being passed along the whole length, thus breaking up the column of water and imparting a rotary motion. There is a minimum of soldered joints, and

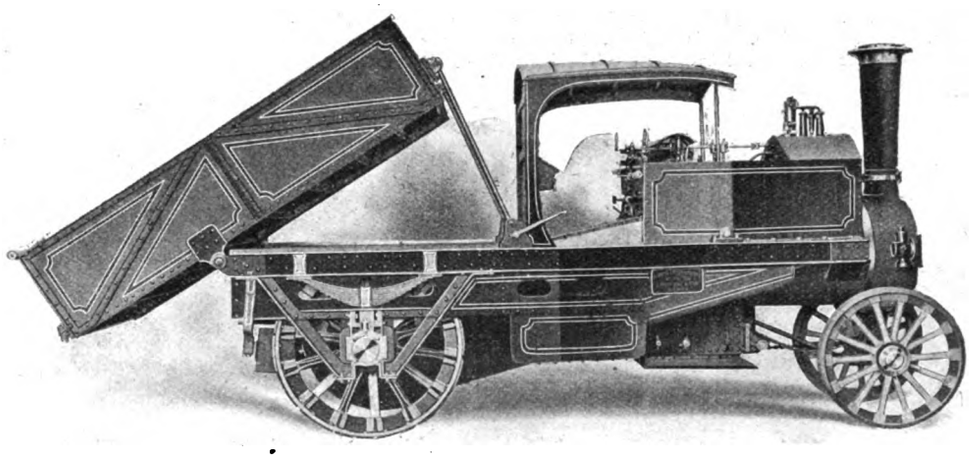

Fig. 31.—The Foden Steam Wagon.

this particular form of radiator requires a very small quantity of water. The Herz sparking plug, which is claimed to work even when covered with oil, is another special feature of this display, which is completed with a selection of asbestos packing rings, detachable cable terminals, induction coils, etc.

MESSRS. FLOYD AND FLOYD, LIMITED, have a good collection of malleable iron castings for motor-cars, engines, etc., and thus emphasize their capacity for meeting the demands of those requiring the productions of that branch of the trade.

Digitized by Google

The Yorkshire Patent Steam Wagon Company are again among the exhibitors of heavy steam vehicles, they having on view a wagon capable of carrying loads up to 5 tons and of hauling 2 tons on a trailer. A detailed description with drawings of this wagon was given in our issue of August 3rd, 1901, but since then many small improvements have been introduced. The boiler is on the locomotive principle as regards the fire-box, but has two short barrels instead of a long one and is fixed across the front end of the frame, making a compact arrangement. Two sets of fire tubes connect the fire-box with the chambers. At each end of the barrels

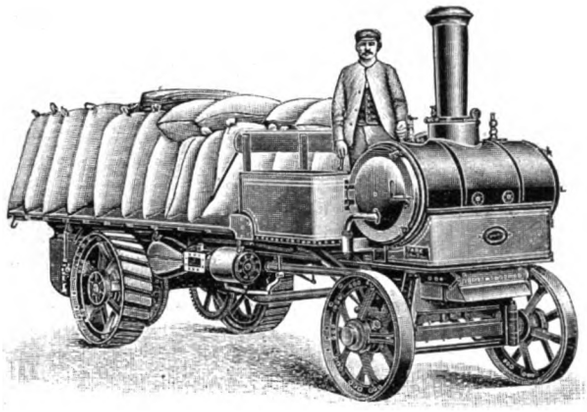

Fig. 32.—The Yorkshire Steam Wagon.

the return tubes convey the gases to another chamber at the base of the chimney. The engine is of the horizontal compound type, with long stroke. Cylindrical guides are provided for the piston crossheads, these having large wearing surfaces, and fitted with dust-proof covers. The power is conveyed to the rear road wheels entirely by spur gearing. The crankshaft is carried in two inverted pedestals bolted to the wagon-frame; to each of these pedestals a strong steel bracket is hinged, which carries the second motion shaft and rear axle bearings; the other ends of these brackets are free to slide on strong guides. The wagon-frame is carried on laminated springs fixed to the brackets by joint pins, and can rise and fall without any material variation in the working centres of the shafts. There are only two bearings to each shaft, and all the gearing is between them; the second motion shafts and rear axle run in swivel bearings, so that, however unequally loaded or how uneven the road, the shafts cannot bind in the necks. The frame is built up of channel steel, and braced with diagonal stays to resist the severe cross strains in travelling on uneven roads. Two speeds are provided, corresponding to 6 and 2½ miles per hour. The front axle is free to rock on the springs, so that no cross strain is thrown on the frame by the unevenness of the road; the road wheels are of the gun-carriage type, drag rods being fitted on the driving wheels to relieve the strain of driving through the spokes.

Messrs. J. Robertson and Son are another firm showing a steam-wagon for the first time. It is designed to carry 5 tons, and is capable of drawing a trailer with 2 to 3 tons The boiler is of the central fired

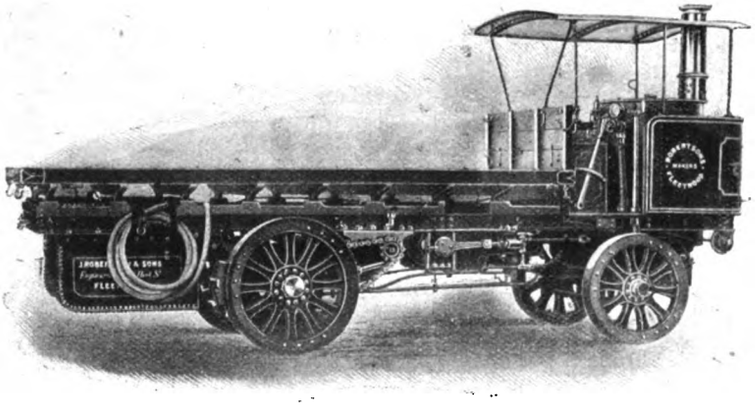

Fig 33.—The Robertson Steam Wagon.

vertical type, but constructed to the firm's patented design, having all the fire-tubes fixed radially and below the water level. The shell is almost completely enclosed by the smoke-box casing, thus giving additional heating surface and ensuring dry steam for the engines. The engine is of the enclosed self-lubricating type developing 25-b.h.p. An illustrated description of this wagon was given in the *Journal* of November 7th last. Messrs. Robertson also have on view one of their patent boilers having an heating surface of 80 square feet and a grate area of 26 square feet. A crank shaft for one of their wagons with all the cranks and eccentric sheaves machined out of the solid forging is also to be seen.

Messrs. Savage Brothers, Limited, who are now devoting considerable attention to the construction of heavy steam vehicles, have a couple of well-finished wagons on view, one of four-ton capacity, having a flat-top lorry body; the other having a tip-wagon body, able to carry a load of five tons. The main framing is of channel steel section, stiffened by gussets and stays. The boiler, which is located in the fore part of the frame, is of the water tube type, suitable for a constant working pressure of 200 lb. per square inch. The steam chamber is a solid-drawn mild steel tube. The circulating tubes are of the "Mannesmann" solid-drawn type. The inlet feed valves are of a patent accessible pattern, which allows of examination of the valve and seating whilst under steam. Welsh coal or coke is used as fuel, 3½ cwt. being carried, sufficient for a day's working. If desired, liquid fuel firing can be adopted. The engine is of the double-cylinder high-speed compound type. The valves are of the piston type and work in valve liners, which can easily be replaced when worn. The valve and reversing motions are of a specially-designed single eccentric principle with large wearing surfaces. All the necessary stop valves and reversing gear are placed within convenient reach of the driver. The feed pump is worked by reducing gear from the crankshaft. A water heater in connection with the exhaust steam pipe is provided, which raises the feed water to a high temperature before entering the boiler. An auxiliary feed pump is also fitted. We noticed that all the steam, exhaust, and other pipes are of solid-drawn copper. Two speeds are provided, the crankshaft being connected by steel gearing with the differential shaft. From the latter the power is conveyed to the rear road wheels by side chains. The chain wheels are attached to the hind or driving wheels by means of steel brackets containing spiral springs, which come into compression when starting the load, thereby relieving the sudden jar on the gearing and motor. The steel driving shafts are carried in malleable steel brackets having compensating gun-metal bearings, which allow for any unevenness of the roads and prevent cross binding. Messrs. Savage also display a number of artillery

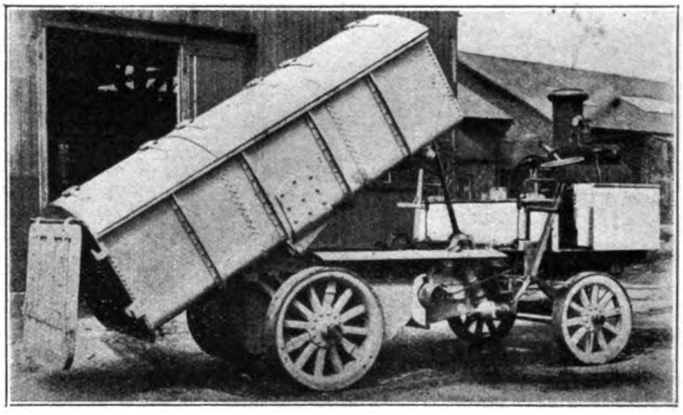

Fig 34.—The Savage Sanitary Wagon

pattern road wheels for use on motor-cars, of which they make a speciality. These are made with twelve or fourteen spokes, in sizes from 34 in. up to 58 in. diameter.

The Begbie Manufacturing Company, Limited, who are known throughout the trade in connection with "Aster" engines, gears, and coils, have a long range of carburettors, Begbie-Audin radiators, back and front axles, lubricators, Begbie-Lamplough steering gears, and other automobile parts. The new models of "Aster" engines are fitted with mechanically-operated valves, and supplied in sizes of 10–12-h.p. and 14-h.p. with two cylinders and 16–20-h.p., 24-h.p., and 30-h.p. with four cylinders. The "Aster" three-speed and reverse gears, actuated by one lever, are supplied complete with differential and clutch, and are suitable in connection with the chain drive. Induction coils of all kinds are supplied by the Begbie Company, and those interested in the subject will find page 9 of their excellent catalogue useful for reference. The Begbie-Oleo sparking plug has been recently referred to in these columns, so that detailed description of its merits is now unnecessary. A good display of lubricators is made by the company, including automatic pressure-feed lubricators working from the exhaust. These are made in three leading types, A being a cast aluminium reservoir with a pump fitted for the crank chamber or gear box, having a black enamelled brass reservoir without a pump, and C working on the same principle as the first-named, but with the sights and feeds arranged on the top of the reservoir instead of the front. The supply of complete sets for motor-car builders is a special line in the Begbie Company's business, and they exhibit a *chassis* of high finish and excellence that is proving very attractive to many visitors thinking of entering the trade.

A puncture-proof device for motor-cars is shown by The Wilton-Cox Device Company. This is made of hide cured by a secret electrical process which renders it very tough, and at the same time soft, light, and durable. It consists of two pieces, one narrower strip lightly sewn on to the wider strip, and thus making a channel or passage right round the

Digitized by Google

inside of the cover. Punctures do not occur direct, but penetrate gradually sideways, lengthways, or across. Therefore, should any nail, flint, or glass penetrate the first wide strip it is detained in the passage or channel formed by the narrower strip, thus entirely protecting the inner tube. The device is unaffected by water, as is being demonstrated at the stand in the Exhibition, and is a non-conductor of heat.

M. ANDRE A. GODIN, whose name is identified with the Ducellier lamps in this country, has a bold show of those powerful illuminating agencies, a conspicuous feature of the display being a yacht lamp throwing its beams across the Gallery. Tail-lights, head-lights, and side-lights for motor-cars are also shown, the exhibit being arranged in pleasant order. Oval paraffin lamps are also on view. In horns is a wide range, including the "Auto-phone," a deep-sounding horn, the volume of groan emitted being increased by the three bends provided to ensure the maximum of noise without adding to the size of the instrument. The "Stentor" is another pattern, which is secured by merely being screwed to the dash-board, no piercing of the latter being necessary. The Sclaverand tyre pump exhibited by M. Godin attained much notice at the Paris Salon, and its introduction to this country will be appreciated by motorists. The pump is fixed on the car, and is put into gear with the motor, air, of course, being pumped into the tyre with each stroke of the piston. Fig. 35 gives a general idea of the arrangement, which has the merit of simplicity. It will be seen that a gauge is provided; this has a two-way tap communicating with the safety valve. The latter has a whistle to indicate when the inflation is completed, and a turn of the tap opens the vent for surplus air. Small and compact—it measures less than a foot, and is only four inches wide—this tyre pump will save time, labour and temper, a triple combination that should be appreciated by every busy motorist.

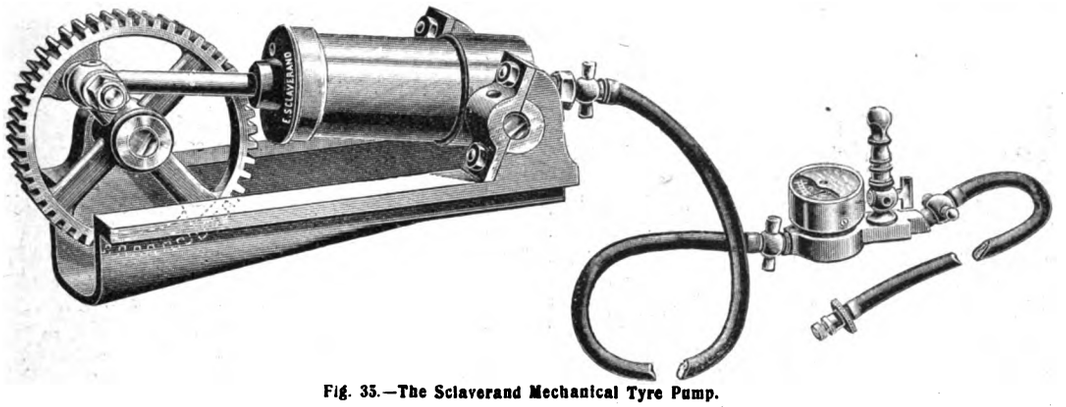

Fig. 35.—The Sclaverand Mechanical Tyre Pump.

Motor castings are shown by MR. ROWLAND HILL, whose productions are well known in the trade. On the stand is a channel steel frame, as well as a selection of radiators, bonnets, tanks, &c., forgings and stampings, cylinder patterns, gun-metal and phosphor-bronze castings, aluminium alloy castings, etc. Mr. Hill undertakes everything of this kind.

The Collier tyres are shown by the COLLIER TYRE COMPANY, LIMITED. Their good qualities and safety under all conditions of travel are well known, and now that a new mode of attachment has been devised there is a renewal of interest in a tyre which has so consistently proved its serviceability. This new plan will be clear from the two illustrations herewith. It is extremely simple, and enables an easy manipulation of the tyre. Fig. 36 shows the new flange fixing with one side of the tyre lifted; and Fig. 37 gives an idea of the tyre with the flange fully fixed in position. Further description would seem superfluous, the two illustrations demonstrating the ease and facility with which the tyre can be attached—an important point which should give still further favour to the Collier tyre.

Of attractive and pleasing appearance is the stand of the BIRMINGHAM ALUMINIUM CASTINGS (1903) COMPANY, LIMITED, whose facility for production enables them to deal with orders promptly as well as efficiently. They have a wide range of motor castings, and number among their *clientele* many of the leading firms in the industry. As a matter of fact, the productions of this company are to be met with on many stands in the Main Hall as well as on their own place in the Gallery. They have a good show of mudguards and number plates, as well as castings, and the general clean and clear-cut appearance of the latter is a characteristic that should help the concern to go even further forward in their particular line of business.

The "Polkey" headlights for burning paraffin are on the stand of MESSRS. GEORGE POLKEY, LIMITED, who have sought to make these popular among motorists who tour frequently. Each lamp contains two cylinders, in which duplicate chimneys can be carried without risk of breakage. These lamps give a well-diffused light and have met with much favour. The Polkey motor and tail lights are made at the requisite angle to illuminate the number on the rear of the car, and comprise an exhibit of real value as well as of interest to motorists.

The latest patterns of the Bleriot lamps, which have sustained a long reputation both on the Continent and in this country, are to be seen at the stand of MESSRS. WELDHEN AND BLERIOT, the special patterns worthy of detailed inspection including the "Populaire" and the "Eclaireur Elliptique" headlights. The combined lamp and horn is another novelty, and there is also a good range of head, side and tail lights designed to meet the new regulations of the Local Government Board, including those mentioned in the *Journal* last week. A new foot-warmer is among the special features of an interesting display, which is completed by a long range of horns.

"LEWIS'S" is the title of a North of England firm identified with the clothing industry for many years, and one which is now becoming favourably associated with that branch which caters for the varied and still-changing requirements of the motorist. They are making a special feature of garments lined with leather, as well as fur overcoats and the like. Several ingenious designs have been incorporated into the making of these motor clothes; hence the interest taken by the trade in the exhibit. One interesting feature of the business is that they are fully equipped to undertake bespoke work at short notice. Lamps, horns, etc., are also on the stand, some special agencies having been acquired by the firm.

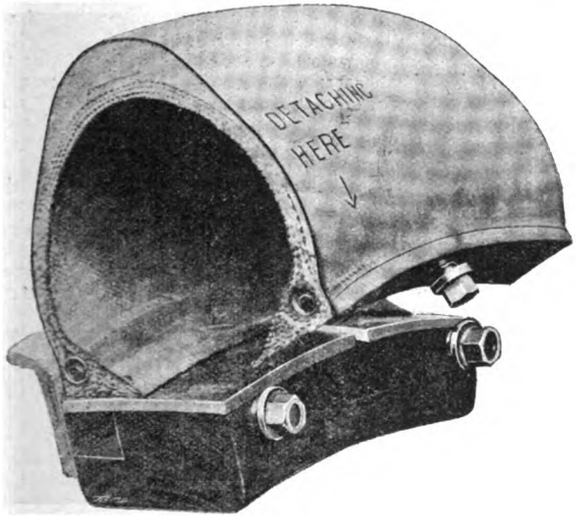

Fig. 36.—The Collier Tyre Detached.

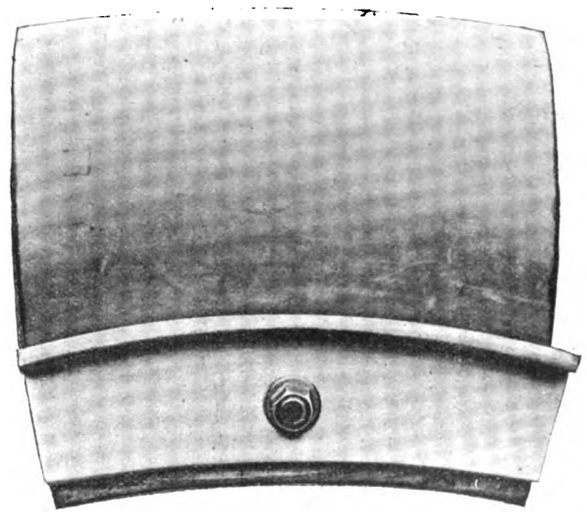

Fig. 37.—The Collier Tyre with Fixing Flange in Position

Digitized by Google

All wool clothing for motorists is attracting attention to the stand of Messrs. Hoare and Sons, whose "Rex" and "Pioneer" motor coats are recognised as standard articles of attire. The "Sandringham" motor coat is another speciality of the firm, whose liveries for drivers complete a representative assortment.

The Imperial Tyre and Rubber Company, Limited, are prominent in the Gallery with recommendations of their work as repairers and vulcanisers of tyres and tubes. This is a branch of work they have made their own, and their wide experience of all classes of tyres is being placed at the service of many leading motorists. They are placing upon the market the "Imperial" tread, consisting of a band of steel leather with steel studs to prevent side slipping. Another excellent idea which finds embodiment on this stand is the "Imperial" grooved flat head, the groove giving the appearance of safety in use. We may add that the company have extensive vulcanising works at Clerkenwell, and are in a position to deal promptly as well as efficiently with motor-car repairs.

"Everything but the motor" is a saying freely published about the stand of Messrs. Alfred Dunhill, Limited, whose collection of waterproof clothing, including umbrella coats and capes, has assumed large and still growing proportions. Neat designs in ladies' millinery, suitable for wear when driving, are quite a feature of this firm's exhibit, and their drencher tweed motoring coats have attracted much attention. In goggles quite a hundred different patterns are to be seen, and in the accessory branch of the business variety and completeness are characteristics. Few firms have gone so completely into the business as Messrs. Alfred Dunhill, Limited, who have lately added to their extensive stock a Duplex lens headlight, to which further detailed reference will be made in a later report of the exhibition.

A new coat is shown by Messrs. H. J. Nicoll and Co. This has a stand-up collar for motoring, which can be turned down in the ordinary form. At the back is a band which buttons across when the wearer is walking, thus taking in the wide skirt, which adds to the comfort of the owner when sitting. A good collection of rainproof coats and garments in frieze is also shown.

Non-skidding devices distributed about the Hall form an interesting section of the Exhibition. In King Edward's Hall is the "Parsons" non-skidding device, shown by the company of that name. This consists of a chain going round the tyre, a creeping movement being maintained when on the road, which prevents the tyres being marked in any one point. These non-skids are made for motor-'buses, heavy and light cars, and also for motor-cycles.

At the stand of the Motor Tyre Manufacturing Company—a company that has facilities for the prompt as well as the efficient repair of motor tyres—will be seen an interesting non-skidding invention in a band of chrome leather with steel inserts. This can be fitted to any make of pneumatic tyre, and is attracting considerable attention.

The Palmer Tyre, Limited, have a good show of their cord motor-car tyres, which have become well known to motorists since first described in our issue of January 9th last.

Accumulators and a general range of motor accessories are to be found on the stand of Messrs. Harvey, Frost and Co., who, however, make a special feature of their "H. F." steam tyre vulcaniser—a machine of equal interest to motor repairers in the trade as to those who have the fortune to own three or four cars with the liability to many tyre troubles. The vulcaniser consists of a bell-shaped base frame for bolting to a bench. Above the frame are the various fittings. These include a hollow cradle, forming a steam chest for live steam. Under it, hidden from view by the flange and upper portion of the bell base, is a dome-shaped bottom, which holds the water, and forms what is practically, in conjunction with the cradle, an ordinary boiler. The whole is tested to more than five times its working pressure. Steam is generated by means of a Bunsen gas burner concealed under the frame, and a door is provided for convenience in lighting the burner. The cock just under the flange of bell base serves the purpose of a water gauge, and the dial and adjoining pipe a steam gauge.

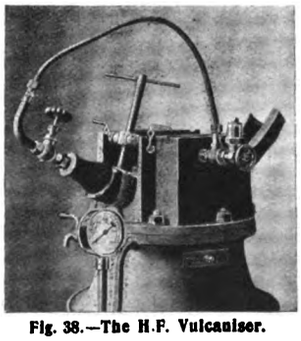

Fig. 38.—The H.F. Vulcaniser.

Steam pressure is generated in the cradle, and inside this is laid a cylindrical-shaped mandrel, the curvature of which conforms to the curvature of the cradle, also of the tyre. The mandrel is tapered at the ends to allow of convenient inlet and outlet connections. Steam is conveyed from the cradle to the mandrel by the means of a flexible metallic tube, with unions at each end, and is regulated by the inlet valve on the end of mandrel, the corresponding valve at the other end being of course for emitting air, steam, or water. A vertical screw with a cross-head is provided to bring adequate pressure to bear upon any given point of the mandrel while resting in the cradle. Tubes of any size, up to 120 mm., can be repaired with this machine without any difficulty in the most rapid way, with consequent economy of time and expense. It is extremely simple, and secures sound repairs by vulcanisation in the most thorough manner; hence its value to the trade.

Motor lawn-mowers of good design are shown by Messrs. T. Green and Son, Limited. These were recently referred to in our columns, and their points of interest are attracting many visitors to a noteworthy stand in the Exhibition.

Messrs. J. Bartlett and Co. are going seriously into the motor-car world, and, in addition to the lamps exhibited, have also for inspection the drawings of new designs of side wings and tanks they are about to put upon the market. In motor-bicycle lamps some good novelties are shown, including an acetylene generator to supply ten lights to a car. This is of the portable type, is very compact, and has two purifiers. There is also on the stand a motor-bicycle lamp with an independent generator which fits on the front fork of the machine. The charge of carbide is sufficient to last for twelve hours, but it need not all be consumed at one lighting. It may be used a few hours, then put by and re-lit, an advantage of real economy. Another generator is designed to fit in the back of the motor-bicycle. All the "Bartlite"—that being the name given these specialities—lamps have a good substance and weight, being of sound construction and workmanship.

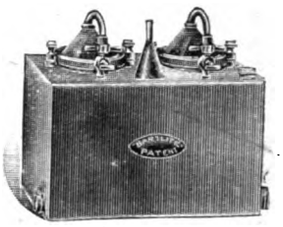

Fig. 39.—The Bartlite Generator.

M. Alfred Dinin, for whom M. Godin acts as manager in this country, has a good show of accumulators, of which, so far as automobile work is concerned, he may be said to have been a pioneer. Here are accumulators for traction and lighting purposes, and charging boards in various sizes, both for garages and private motor houses.

The patent "twin-spoke" artillery wheels, specially designed to withstand side strains, are exhibited by the Artillery Wheel Works, Limited. These were illustrated in the *Journal* so recently as the 27th ult., so that further reference seems unnecessary. Their pleasing appearance, however, is doing something to secure their adoption by builders of cars. On the stand is a twin-tyre wheel with 3½ in. solid tyres fitted on a 8-inch rim, for a steam motor-'bus ordered by the North-Eastern Railway Company.

Messrs. Peto and Radford, Limited, have their usual large selection of batteries, accumulators, plugs, etc., as well as a varied assortment of electrical testing instruments. Minor improvements are noticeable in several of these, the firm apparently being always experimenting with a view to increasing the efficiency and reliability of their devices. In the accumulators we notice the terminals are now being placed as far apart as possible, and the fine finish given to all these productions is a demonstration of the care with which Messrs. Peto and Radford are catering for automobile work.

Among the miscellaneous exhibits will be noticed the "Bluebell" metal polish, the "Buttercup" metal polish, the "Rocket" metal polish (which is free from acid and non-inflammable), and "Quixol," a preparation for cleaning and renovating leather.

Seddon's motor tyres are shown in the Arcade Gallery, these being produced by Messrs. D. Moseley and Sons, Limited, from red rubber, in accordance with the ideas of Mr. E. H. Seddon. Previously has reference been made in these columns to the Seddon tyre, and it remains but to be said that the construction is designed to secure great strength, and to prevent the chafing of the cords used in the manufacture. A square tread of about 1½ in. in width is provided, covering so small a road surface that side-slip is obviated.

Messrs. Holding and Sons are drawing the attention of motorists to the "Car Poncho," illustrated in our issue of February 27th. This is a capital idea for a motor waterproof, combining the familiar *parapluie* with a collar of stylish appearance. The "Ayrshire" motor ulster, the "Holding" patent apron, the "Kangaroo" motor vest, are other specialities shown at this stand, where will also be found a good assortment of dustcoats and smocks, ladies' coats and furs, as well as drivers' liveries and motor-cycling outfits. A camp outfit is also on view.

Varnishes and paints for motor-cars are to be found on the stand of Messrs. Docker Bros., Limited, who have adopted an improved process in the manufacture of their specialities. Their motor paints are ground in a specially prepared quick medium, no dryer of any kind being used. The covering power of the paint has been increased, and work of a high and smooth finish ensured, as can be seen by inspection of many of the cars in the Hall. The paints have the valuable property of resisting the effects of heat, an important point in automobile work, and they may be congratulated on their first appearance at these Exhibitions.

Messrs. Bowley and Son are taking advantage of the Exhibition to draw attention to their lubricants for petrol motors, and to their motor-spirit. This oil is supplied in two gallon rectangular tins, and has attained considerable celebrity. During the past few days it has been prominent in connection with the 1,001-mile non-stop run of the Georges Richard car, it having been used for the whole of the distance. In lubricating oils are also shown their "Champion" oil, this being specially recommended as one that will not "gum," give any acid reaction, nor at increased temperatures appreciably lose its viscosity.

The Motor Castings Company have a large assortment of motor accessories and castings of all kinds. Special attention is drawn to their complete set of motor-bicycle castings, and also water-cooled castings for a 6-h.p. set De Dion pattern. A collection of tools, including spanners, bolts, etc., complete a very comprehensive display.

Digitized by Google

Engineers' stores and motor-car requisites are a feature of the display of Messrs. George Skudder and Co., who have long been associated with the preparation of special oils and lubricants for automobiles. They have on their stand samples of Skudderlene oil for water-cooled and air-cooled motors for bearing and for gear boxes, as well as Skudderlene lubricant for steam, petrol and hot air engine bearings, differentials, etc. Gripolene is a preparation for preserving belts of every description and preventing them from slipping. Raw hide belts, asbestos and rubber goods, belt lacing, etc., are also to be found on this stand.

A. W. Gamage, Limited, have a large stand for the exhibition of the thousand and one motorists' requirements stocked by them. Patent tyre levers, new trembler coils, etc., are here to be found as well as the Cossor combined petrol gauge and densimeter for attaching to petrol tanks.

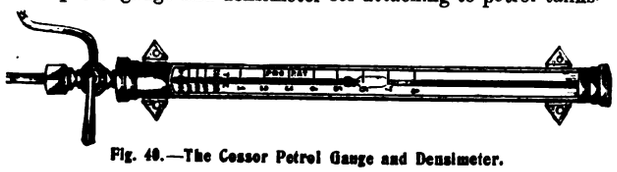

Fig. 40.—The Cossor Petrol Gauge and Densimeter.

and of which an illustration is given in Fig. 40. Non-slipping tyre devices and a complete selection of accessories for motor-cyclists should attract attention to this display. The clothing section of the exhibit is an important one, the special features including the firm's patent coat with detachable camel-hair lining, enabling the garment to be used either as a driving coat or an ordinary walking coat.

Mr. David Perry is showing his patent Acme Packing for the glands of steam-cars. This packing consists of three cores, so arranged as to present an oval appearance in cross section, two of the cores being laid side by side as concentric rings, while the third lies upon and intermediate to the other two, thus forming a packing of great elasticity and frictionless working. In some engines packed with it the tool marks are not out of the piston rods after constantly running for nearly two years, day and night. The packing also possesses a compensating property, so that as the layer next to the rod (or plunger) wears, it is caused by the pressure of the gland to slide upon the adjacent layer and is automatically replaced by fresh material, a large portion of the packing being actually utilised. The result thus attained is a large saving of steam, a proportionate saving of fuel, and the life of the packing greatly increased.

A high style of coach work is to be seen at the stand occupied by Messrs. W. and F. Thorn, who have given study to the design of appropriate bodies for automobiles. Vehicles with side doors, removable canopy and wind shield are a prominent feature of this display, Messrs. Thorn having thought out some minor points of construction which should do much to popularise these particular bodies among the trade. Attention is being given to providing bodies of a detachable or adaptable character—a feature in which coach building firms are endeavouring to meet the requirements of the motor-car industry. Messrs. J. Liversidge and Son, Limited, make a bold show of artillery wheels and patent radial wheels, many of which are fitted with the De Nevers patent solid motor tyre—a type of tyre designed to prevent skidding and secure a good grip of the road surface.

Patent solid rubber tyres for motor-'buses and similar heavy vehicles are the main attraction on the stand of Messrs. J. E. Hopkinson & Co., Limited. The idea embodied in the construction of this tyre is well brought out in the accompanying illustration, Fig. 41, which is a view of the lateral section of the tyre, showing the method of fixing. The rubber tyre is fixed in an endless circular steel flange, which is secured

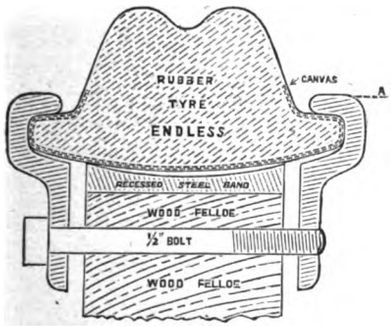

Fig. 41.—The Hopkinson Tyre, before fixing.

to the felloe by a retaining bolt. There are no wires embedded in the rubber, and the makers claim that this method secures strength and durability, as well as resiliency and efficiency.

Motor-cycle belts, tyre gaiters, and raw hide belting form the substance of the display made by Messrs. Elliott Hallas and Sons, Limited. The motor-cycle belt is made from selected raw hide butts, each strip being without joint. Their "Elothas" belt has been in use during the past season, and one rider reports having used a large section belt for upwards of 9,000 miles, with very good results. The "Elothas" dressing for leather belting is also shown by this firm, whose motor tyre gaiters present some points of excellence.

Messrs. W. Beardmore and Co., Limited, have a capital display of pressed steel frames in various sections, special features including mild steel pressed frames for 12-h.p. and 16-h.p. cars. Sections are also shown of hydraulic riveted joints, as well as of flanged steel plates for steam wagon boilers, and a steam wagon wheel with weldless angle rings and cast steel shoes.

Their well-known patent mowers with 2¾, 3½, or 6-b.h.p. motors are exhibited by Messrs. Ransome, Sims, and Jefferies, Limited, who have long—so far as the automobile movement is concerned—been identified with this class of work. The smaller size machine is specially devised for use in small grounds of from one to three acres.

The Car and General Insurance Corporation, Limited, draw attention to their several departments of business in which the issue of insurances and indemnities in connection with motors and motoring figure largely. A special feature is made of insurance against driving accidents. To cover all risks incurred by motorists the General Accident Assurance Corporation, Limited, now issue policies of insurance, and wisely take occasion of the opportunity presented by the Exhibition to make the fact known to those who motor. Similarly, the Law Accident Insurance Society, Limited, draw attention to their system of insurance, which includes indemnity against personal injuries, claims by the public, damage to cars, or loss by burglary, etc. The Horse, Carriage and General Insurance Company, Limited, are not unmindful of the growth of automobilism, hence their appearance at the Show to issue policies of various kinds.

The Gare patent tyre-setter, a hand-power machine for fixing without heating rims and tyres on any class of wheel, is on the stand of the Gare Patent Tyre and Wheel Company, Limited, of Liverpool. Two steel bands are placed round the circumference of the wheel, the two ends of each being drawn together by levers worked by left and right hand screws. As these are drawn, the wheel is contracted to the size required. Then it is measured, and accuracy having been obtained, the tyre is welded up exactly to that size. When the tyre is ready for fixing on the wheel, the top steel band is taken off, the bottom one being left on the wheel, being still under tension. Tyre levers are utilised to pull the tyre on the wheel and force it down to the bottom band. The remaining band is then taken away and the tyre forced down, the work taking only a few minutes. The machine is a saving of time and labour, and highly efficient. It also provides a good test for wheels, and is proving an object of interest to those associated with the trade. The "Gare" tyre tangent spoke wheel and patent resilient motor-wheel are also on view at this stand, the latter being shown in Fig. 42. This is for heavy motors, and, while being somewhat heavier than the ordinary type, has advantages in its greater resiliency and non-skidding qualities. It is built up with blocks of wood placed tangent to the hub, V-shaped sections, embedded in rubber, form the wearing surface, being held by metal flanges.

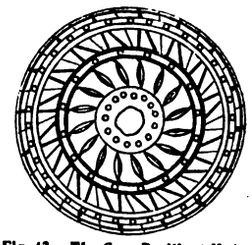

Fig. 42.—The Gare Resilient Motor Wheel.
For heavy vehicles, the hub, with V-shaped sections bedded in rubber.

Of jacks Messrs. Lake and Elliot have a great selection, several patterns and sizes giving a practical turn to their exhibit. Long handles and quick adjustments are points of value in connection with these necessary adjuncts to the motorist's equipment. A new pattern of the firm's "Millennium" jack is on view, and for motor-cycles there is a neat carrier stand known as the "Millennium," in which the luggage may remain on the carrier when the stand is in use. This will practically fit all motor-bicycles.

Ignition coils of good design are exhibited by the British Ignition Coil Works, who have a special department for the repair of coils, and have recently laid down a new plant for the manufacture of coils in large quantities.

Messrs. J. W. and T. Connolly, Limited, have an important exhibit of Goodrich side wire motor tyres in 5-in. and 6-in. sections, as well as of artillery wheels, etc. In view of the development of motor-vehicles for heavy traffic, the Goodrich tyre deserves attention, and its long career of advancing usefulness in the United States is likely to have equal repetition in this country. The method of attachment is simple, there being cross wires at intervals of every inch to the side wires, absolutely securing a reliable tyre for the heavier class of motor-vehicles.

Messrs. Van Raden and Co., Limited, may always be depended upon to have a good show of electrical accessories, and among the special objects of interest on the present occasion are the coils and accumulators to be used on the Wolseley cars entered for the Gordon Bennett Eliminating Test. New patterns in the woven glass accumulators, a new petrol gauge and drip, by means of which the amount of petrol in the carburettor can be regulated, and also be made known to the driver, and an electric portable lamp for use in petrol stores, motor houses, and similar places are other notable exhibits in an interesting collection.

Motorists who find a difficulty in obtaining anything like a permanent motor stable will be interested in the motor-car house which occupies the stand of Messrs. Quibells. This is known as design E, and is 8 ft. wide, 12 ft. long, and 7 ft. high. It is roofed with 1 in. grooved and tongued and filleted boarding, the sides being of feather-edge boarding, tarred. Models of other houses are also on view, and sufficient is shown to testify to the firm's capacity for a large output of well-designed houses.

(To be continued.)

BECOMES OF OLD MOTOR-CARS.

WHEN a motorist decides to part with his car in favour of a new one the step is taken not so much through the failure to perform its function as a self-propelled vehicle, but rather on account of its lack of speed, some inconvenience or unpleasantness of operation, and more particularly on account of its not conforming to accepted standards of taste in appearance or equipment. These vehicles, when "cast off" by their buyers, usually are but little worn in any parts save those which are readily replaceable, and oftentimes years of service may still be expected from them. The engines of petrol vehicles, even those which were constructed very early in the history of the art, were, as a rule, quite long lived, and this may also be said of many of the earlier change-speed gears, and of some other parts of the mechanism. Quite a number of these veteran machines are still capable of service according to their merits. The majority of them were discarded simply because they were out of fashion, and, as the dictates of the fickle goddess are most imperative in large cities, and the standards of automobile taste are there most highly developed, such vehicles find their way to the smaller communities, where a motor-car is judged more by its ability to get about than by the shape of bonnet which it wears. After a time these machines generally find their ultimate fields of usefulness in country places, where they often do good service before the final denouement on the scrap heap.

It has been decidedly interesting to note this constant stream of discarded vehicles making its way from the metropolis to the rural communities, and it has been particularly well marked in the case of the light steam car which was so popular a few years ago. While formerly these cars were common in large centres, they are now quite exceptional, but if one visits the more remote districts one will find them held in high esteem.

During the vicissitudes of its eventful life history, the discarded vehicle suffers, remarks the "Horseless Age," many changes in appearance and equipment, and frequently is so modified by its successive owners as to become unrecognisable to its first possessor or to its builder. Its wheel base may have been lengthened, a new body with tonneau may have been put on, it may have been supplied with wheel steering, with an improved ignition system, with a radiator of advanced type and with other up-to-date improvements, so that the engine and perhaps the change speed gear are about the only means of positively identifying it. Its period of usefulness is greatly protracted by these changes, and it is likely, if intelligently refitted, to do good service until it arrives at an honourable old age.

A MOTOR-CAR competition up Buckham Brow is one of the suggested attractions at the next show of the Settle Agricultural Society.

WITH reference to the receivership in connection with the Lanchester Engine Company, Limited, we are asked to give an assurance that this is only of a temporary nature, pending the scheme for reconstruction now under consideration. Orders placed with the concern will receive immediate attention, and business is being carried on without a break.

THE Agricultural Hall presented a lonely sight on Sunday, when, deserted by public and exhibitors, it was practically empty of humanity. Three or four firms, however, took advantage of the occasion to make sundry alterations to their stands, and in some cases to practically construct their vehicles. In fact, one stand we saw looked more like an engineer's workshop than anything else.

MR. JULIAN W. ORDE, secretary of the Automobile Club, arrived at Douglas on Tuesday to make arrangements for the holding of the English eliminating trials in connection with the motor race for the Gordon Bennett Cup in the Isle of Man. He was met by Lord Raglan, Lieutenant-Governor, the chairman of the Manx Highway Board, and others interested, with whom he had a conference. On Wednesday he went over the proposed course accompanied by Lord Raglan.

OUR DIRECTORY OF "NUMBERS."

CORRESPONDENCE.

THE EXHAUST VALVE LIFTER AND VALVE GRINDING.

To the Editor of *The Motor-Car Journal.*

Sir,—As there is considerable discussion going on among motor-cyclists just at the moment in regard to the advantages and disadvantages of the exhaust valve lifter, we thonght possibly the experience of one of our clients at this stage would be interesting. Some writers appear to be under the impression that the now almost universal use of exhaust valve lifters upon motor-cycles is the cause of frequent valve grinding being necessary; and to those who complain that their valves require grinding in every 500 miles we should without hesitation say that this is more likely owing to the material used not being satisfactory. We have received a letter from one of our clients who has ridden over 10,000 miles upon a motor-bicycle fitted with one of our own engines, who writes as follows:—"After 10,000 miles it has never overheated; the exhaust valve has never been ground in; the inlet and exhaust springs are the original ones and are as good as new." During practically the whole of this time our client assures us that he has had an exhaust valve lifter fitted and has been in the habit of driving upon the exhaust valve. Some riders appear to think that the cause of the exhaust valve seating getting burnt and pitted is that owing to driving on half compression the charge passes out of the exhaust port in the form of a flash. The same thing happens whether an exhaust valve lifter is fitted or not; and to riders who hold this opinion we would recommend that they run their machines in the dark with the exhaust connection to the engine removed; and it will be found, when the machine is running at anything like an average pace, that a large proportion of the ignited charge passes through the exhaust seating in the form of a flash. In our opinion there is far too much valve grinding done by the average novice; it is almost an impossibility to grind a valve in properly in the way that a good many adopt, *i.e.*, with an ordinary screwdriver, and unless the valves are ground in properly they are far better left alone. We think a word of warning at the present juncture is really needed.—Yours truly,

The Ariel Cycle Company, Limited.

CHANGING SPEEDS.

To the Editor of *The Motor-Car Journal.*

Sir,—In answer to "F. J. R.'s" enquiry in the last issue, I may state that in charging speeds it is usual to let the clutch in as quickly as possible after the gear is changed, although not with a "bang," as a great deal depends on this as to whether the car picks up speed or not, especially in the case of a small-powered car. The idea of a change speed gear is, of course, to work the car up gradually to a speed, and if time is lost in letting the clutch in, the vehicle naturally slows, and in some cases the engine becomes overworked and eventually stops. The only time it is necessary to put the clutch in slowly is when pulling away from a standstill, but once the car is moving it is best to get it in as quickly as possible.—Yours truly,

H. J. T.

BENZ v. LIGHT CAR.

To the Editor of *The Motor-Car Journal.*

Sir,—In answer to "Doctor," "G. L. B.," "Solid Tyre," and others, I thoroughly fall in with what they say, and especially so about the confusion with the types of Benz cars. It seems to me that when a Benz car is mentioned the majority of people laugh, and think the old 3½-h.p., driven with two or three narrow belts, is referred to. I have one of the 7-h.p. geared Benz cars, with tonneau body to carry four persons, referred to by "Solid Tyre." I have had it twelve months, run it over 5,000 miles on good roads and bad, and the same belt is on now as came with the car when new. It has been taken up only twice in the year. The car caused no trouble whatever; it has three forward speeds and reverse, and can mount any hill with full load—in fact I have passed cars of much larger power on hills. I find the belt drive a sweet one and free from jumping when starting, as is the case with some clutch cars I have seen—in fact, I would not exchange my belt-driven Benz for any other of the same power. I believe it to be most reliable and one I can always get back home on. I have solid tyres—no fear of having to pump wind on my journeys. The car is so beautifully sprung that I find it as easy as many that have pneumatic tyres; I have had no trouble in getting overheated, and the lubrication is so simple and efficient it is almost impossible to run dry. I may say I am not interested in any car firms; I am only speaking of my car as I find it.—Yours truly,

Belt and Gear

The Baby Peugeot No. 2. (*See page* 75.)

THE MEANING OF THE TERM "HORSE-POWER."

To the Editor of *The Motor-Car Journal.*

Sir,—Will you kindly state the actual meaning of the term "horse-power" as ordinarily used in connection with motor-cars? When a salesman informs me that a certain car is of 10-h.p., what does he mean? Is it a fact that a motor will develop more horse-power at 1,000 revolutions per minute than at 800? Does the advertised horse-power of a

Digitized by Google

car mean its greater possible output, or is it understood that the term applies to the vehicle at a definite rate of speed? A few days ago, a motor agent told me that the horse-power of a certain car was 12, and a few minutes later the engineer of the company building the vehicle said that it was 10.—Yours truly,

PUZZLED TYRO.

[The meaning of actual brake horse-power of an engine is the greatest power developed at a given speed, but by an increase of speed the horse-power also becomes increased. Therefore if an engine is tested to develop 10-h.p at 800 revolutions, by increasing it to 1,000 revolutions the horse-power also increases in proportion. The advertised horse-power of a car is usually the power of the engine that is fitted to same, no allowance being made for friction through the transmission.]

MOTOR RACING ON ENGLISH SHORES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR, In America they run their motor races on the seashore, where they have plenty of room. Have we ever considered the possibility of racing on the hard sandy beach of Filey Bay, in Yorkshire? When the tide is out there is a beautiful stretch of hard, solid, dry sand, five miles long at least, and very wide. I have often cycled there, and the going should be excellent for motor-cars. Why go to the Isle of Man when we have so good a track in Yorkshire?—Yours truly,

YORKSHIREMAN.

THE AUTOMOBILE AND CYCLE ENGINEERS' INSTITUTE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am quite in accord with Mr. Hill's letter of last week; in fact, I for one have advocated for some time past the amalgamation, if possible, of the two bodies. I would suggest, however, that the new society be termed "The Institute of Automobile and Cycle Engineers," this being more in conformity with that of other institutes. The word "Automobile" would, of course, prevent any possible clashing with the Institute of Civil Engineers.—Yours truly,

A. A. HURREN, A.M.C.E.I.

WATER IN CRANK CHAMBERS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In clearing out the oil-containing crank chamber of the motor on my 6-h.p De Dion car the other day I was surprised to find a large quantity of water flow out with the oil. I have been puzzling over this, but cannot understand where the water originally came from and how it got in the crank chamber. Perhaps some fellow motorist who has had a similar experience can give an explanation.—Yours truly,

LUBRICANTOS.

[This is perhaps due to a small leakage through the plug in the cylinder head, which is fitted under the sparking plug for water inlet, but failing this it may be caused by condensation in the cylinder, and then work itself by the rings, or it is quite possible that water may have found its way into the oil tank, either whilst washing the car or perhaps in the can containing the oil when purchased.]

WATER CIRCULATION.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Will you kindly tell me if it is wise to fill the tank with cold water when the engine is very hot? If my tank and engine are very hot after a forty miles run, I should otherwise find it necessary to wait a considerable time for the water to cool naturally. By adding cold water my engines, etc., become cool very quickly.—Yours truly,

FACTA.

[In answer to "Facta's" letter *re* putting cold water in the tank when the engine is hot, there is no danger whatever in doing this, providing the water is constantly above the cylinder head. If the water be allowed to get below, and the cylinder become over-heated, there would be the danger of cracking the cylinder, but if care be taken to give a plentiful supply, there is no danger of this, as by putting in cold water the heat gradually diminishes.]

STEAM CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—As a strong admirer of the steam car I have been greatly struck by the uniformly good reports from America of a car called the Stanley. I would like to hear the experience of some users of the car on this side of the water. Of course we all know that the higher priced cars, such as the White and the Serpollet, give every satisfaction, but this Stanley is a cheap car, and I would like to know if what the Americans claim for it is borne out in practice.—Yours truly,

NORTHERN STEAMER.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I notice a writer this week speaks against the wheel valve being used for driving in place of the usual lever throttle valve. My experience is that this method is far superior to the lever, as a more steady start can be made and no fear of the handle being jerked forward by jolting of car. I propose that the valve used is not under one-quarter or better three-eighths and fitted with a coarse screw about eight to the inch. With this only about three-quarters of a revolution is required to drive at a fair pace, and all racing of engines is avoided. To obtain best results from a steam car one has to be a careful, observant driver, and I consider this kind of car is best suited for users of moderate means, the upkeep being very low owing to absence of gear boxes, sparking plugs, coils, &c. I have made use of my Locomobile about the City and find I obtain best result by arranging automatic regulation to cut down fire at 150 lbs.; this allows the car to stand a long time without steam pressure getting up too much; the regulator can be readily set for country work when wanted. I quite agree that the steam cars are too lightly built, but if driven with care and moderation a lot of useful work can be got out of one. Many motorists expect far and away too much from these little cars, consequently they have trouble and condemn the car for what is purely their own fault. I have driven many hundreds of miles and never been hung up yet, but have passed plenty of splendid petrol cars (of more value than fifty of mine) in a bad way and once towed one for several miles.—Yours truly,

W. T. W.

A MOTOR-CYCLE ACCIDENT.

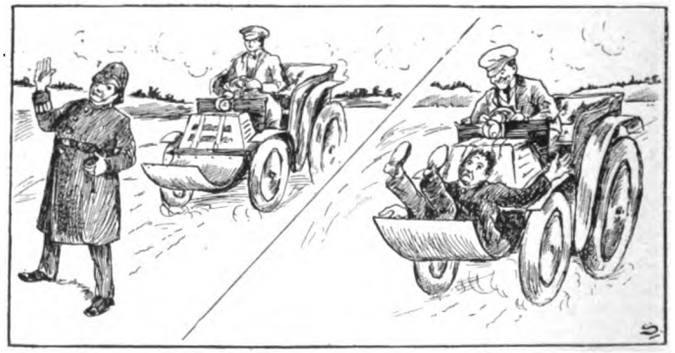
TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have read your advice to "tap twiddlers" in the last issue of the *Journal*. While I agree with you as to the danger of such practice, I feel that the paragraph may lead some of your readers to infer that my son was of the tap-twiddling class, while, as a matter of fact, he was not only a competent motor-driver, but had also been through the mechanics' shop, and had fully three years' experience of the motor trade, being within a few weeks of the 17th birthday. From evidence of eyewitnesses my son was not riding at an excessive speed, but it was outside his power to do other than he did, and the combination of a tradesman's truck pushed by a boy from a side street on to the main road, and the electric light standard in the centre of the road, proved fatal obstacles.—Yours truly,

J. W. GREGG.

[We regret very much that our remarks were open to the inference that the accident to Mr. Gregg's son was due to incompetency. Our object was more to draw the attention of motor-cyclists to the dangers of traffic riding and of urging them to exercise caution. We extend our sympathies to Mr. Gregg in the loss of his son, who was a young and promising motor-engineer.—ED. *M. C. J.*]

THE ROADS INTO WARRINGTON.



TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—May I be allowed, in the interests of motorists and motor-cyclists, to call the attention of your readers to the above-named town, which I must class as by far the most dangerous place in the British Isles in wet or greasy weather. There is, both on the northerly and southerly entrance, a double line of tram-lines—ruts should be their name—about as wide as a motor-car tyre, and once in them on a greasy day to get out of them is impossible without a skid, the size of which depends on the driver mostly. The sets between same are always very dirty and are covered with a black ooze or slime. I know many of the most expert and careful drivers who have got into lumber there; bent wheels and axles are a common occurrence. The tram "ruts" occupy the whole road, thus making it impossible to give them a miss.—Yours truly,

ONE WHO KNOWS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Your comment regarding the stupidity of pedestrians is not fair. It is the silly, stupid rules of the road which confuse pedestrians. It will, I think, be admitted as an axiom, that one rule, or one anything, is more easy to remember than two. Why, therefore, try to perpetuate two "Rules of the Road"? What possible advantage is there in requiring mounted people to "keep to the left," and requesting pedestrians to "keep to the right"? It is a source of serious danger. Why, therefore, do not the authorities issue an order that there is but one "rule of the road" for all—mounted and dismounted? Then it would become an

Digitized by Google

instinct, now it is very confusing. I get off my bicycle and go into the stores, and if I am not thinking, I instinctively keep to the left, and find myself going up the wrong stairs, and, as a vast majority of the public ride something, this causes confusion. Again, two rules of the road necessitate a third rule—namely, the rule between mounted and pedestrians, and this, as far as I know, has not been defined, and if ever published, will never be correctly carried out.

At present, if I am on my motor-car and meet or overtake a mounted person, I know exactly what he will do (except, of course, in Ireland, where we always "go agin the law,") and what I will do. But if I meet pedestrians they do not know what to do, nor do I. Is not this a source of serious danger? And would it not be easily got over by having but one "rule of the road," and this rule instilled into children at school? I wrote on the subject to the Lord Mayor of London and other local mayors, to the head of the London police and others. Most of them seemed to agree with me, but wound up with *non possumus*, which is non-sense. I am surprised that the motor press has not taken up the subject. In towns the roadway and the two pavements should be each considered separate roads, and in the country the roadways and footpaths.—Yours truly,

J. R. MAGRATH (Colonel).

DRIVERS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—As a reader of your valuable paper for some years past, I have always taken a keen interest in your correspondence. The question *re* drivers that has arisen has greatly interested me. I have to take on hands for motor work and driving for the firm I am with. For my part I should never think of employing a present-day certified man or youth. I have tried two or three of this class, and found them inefficient in every manner. If the car stops, say, for a petrol pipe being choked, they will certainly never think of looking for trouble in that direction, they generally take out sparking plugs and valves to look for the trouble. I find it pays better to have a good fitter than half-a-dozen certified men, and I shall continue to think so until men have to pass an examination such as "Adsum" and "Mechanic" suggest.—Yours truly,

FOREMAN.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I will give an example of another trouble as regards drivers. I was driving a car for a large shipbuilding firm, and it became necessary to have an extra driver. Judge of my surprise when a so-called driver came on for 25s. a week (married), with the usual tale of the knowledge of about a dozen different cars. He did not know what a scriber was for. Anyway, I drove out with him to see what he was like, and I pitied the engine. He is the same to-day, so I left him to it and went back to the bench.—Yours truly,

A. A.

PRIMARY BATTERIES FOR CHARGING ACCUMULATORS.—Replying to Mr. W. A. Woodley, these are made by the Boron Battery Co., 131, St. Domingo Road, Liverpool, and Messrs. C. Fuller and Son, of Woodland Works, Wick Lane, Old Ford Road, London, E.

BOOK ON PETROL MOTORS.—Mr. H. Downing, who enquires for a work on the petrol motor, is recommended the one on "The Automobile," by Paul N. Hasluck, and published by Messrs. Cassell and Company.

MOTOR PLOUGHS.—Mr. J. J. Clark, who enquires for the names of makers of motor ploughs, is referred to Mr. Dan Albone, Biggleswade, Beds.

CLUBS AND ASSOCIATIONS.

THE SCOTTISH AUTOMOBILE CLUB.

THE third annual general meeting of the Western Section was held at Glasgow, on Monday, Mr. John Adam, of Larchgrove, chairman of the section, in the chair. The annual report showed the membership of the Club to be 226, an increase over that at the corresponding date last year of ninety-six, and that there was a considerable balance at the credit of the accounts. The report also stated that the handbook of hotels, petrol and charge depots, etc., will be ready for publication very shortly, and that the question of fixing a standard of density of motor spirit and other matters in relation thereto has been under the consideration of the Committee. Reference is further made to the relations between the club and public authorities, and to negotiations which have taken place with regard to the Motor Car Act, 1903, and matters arising therefrom, as well as to restrictions on the use of motor-cars which have been proposed in various instances. It is claimed that considerable advantage has resulted to the club and automobilists generally from the action of the club in these connections during the year. The report and accounts were unanimously adopted. The Honourable the Lord Provost, Sir John Ure Primrose, Bart., was re-elected Honorary President, and the following were elected the Committee for the ensuing twelve months:—Messrs. John Adam, H. W. Brock, Nicol P. Brown J. B. Talbot Crosbie, W. H. Kingsbury, D. McColl, T. Blackwood Murray, Henry M. Napier, James R Nisbet, H. Prosser, John M. Ross, J. B. Shanks, Robert J. Smith, Thos. Symington, and William Weir.

YORKSHIRE.

A GENERAL meeting of the Yorkshire club has been held at the Leeds headquarters, under the chairmanship of Mr. King, of Harrogate. The new draft of rules was thoroughly gone through, and with a little alteration was finally adopted, and the hon. secretary instructed to have them printed and sent to members. Runs were arranged for April 9, 16, 23 and 30, to Aberford, Ilkley, Doncaster and Boroughbridge respectively.

THE BRAKE POWER OF MOTOR-CARS.

SOME official tests were made by Mr. E. Hall Brown, Vice-President of the Institution of Engineers and Shipbuilders in Scotland, on the 14th and 15th inst., for the purpose of ascertaining the distance which a 10-h.p. Argyll car would travel after the brakes had been applied. The car was of the standard 10-h.p. Argyll pattern, fitted with tonneau, and carried the driver and the Observer. It was equipped with the usual foot brake and hand brake, and the tyres were pneumatic. On the 14th the roads were not quite dry, as there had been frost in the morning and the sunshine had softened them slightly without completely drying them. On the 15th the roads were somewhat dryer.

Mr. Brown in his report states:—The method of testing was as follows: The car was run on the level road and timed between milestones, and was set for a speed of practically 20 miles per hour. The speed having been fixed, the adjustment of the engine was allowed to remain unaltered during the tests. The distance travelled after the application of the brakes was determined in the following manner: A body of suitable shape to prevent movement after it fell upon the road was dropped from a height of four feet above the ground at the same instant that the signal was given to the driver to apply the brakes. The distance between the body lying on the road and the position in which the car stopped was then measured. To this measured distance was added the distance which the body would travel forward while falling four feet. In other words, as the body would take half a second to reach the ground from a height of four feet, and would at the same time have the forward velocity of the car at the speed for which the engine was set, viz., 20 miles per hour, the distance of 14·6 feet would have to be added to the measured distance on the road.

Upon this basis, the results of the tests were as follows:—

Speed of Car.	Number of Brakes Used.	Distance traversed after application of Brakes.
Trials, 14th March, 1904.		
20 miles per hour	one	17·88 yards.
15 „	two	13·66 „
20 „	two	13·55 „
19·6 „	two	13·88 „
20 „	one	10·88 „
Trials, 15th March, 1904.		
21·5 „	one	10·91 „
20 „	one	14·21 „

The Hozier Engineering Company decided on having these private tests made in order to prove the actual distance in which one of their cars can be stopped when going at approximately twenty miles per hour, they having found a great deal of doubt about this matter in the public mind. In concluding his report Mr. Brown states that he is convinced that upon ordinary macadamized roads, under the conditions in which the tests were made, this car can be stopped at a speed of twenty miles per hour within twelve to eighteen yards from the point at which the brake or brakes are applied. It would also seem that as the foot brake is sufficiently powerful to cause the wheels to skid, as quick a stop can be made with one brake as with two.

RESPONSIBILITY IN REGARD TO DRIVERS.

AT the Marylebone County Court, on Monday, before Deputy Judge Fitzroy Cowper, Friswell, Limited, sought to recover £21 5s. from Dr. F. F. Burghard, of Harley Street, W., the claim being in respect of the supply of a chauffeur, and of work done to a motor-car. The defendant counterclaimed for £40 for loss alleged to have been suffered owing to the negligent driving of one of the plaintiffs' servants.

It was explained that the case involved an important question as to trade custom, namely, whether the plaintiffs were responsible for negligent driving on the part of the chauffeur sent out by them to the defendant's orders—presuming there was, in fact, such negligence.

Mr. G. Lewin, manager to the plaintiffs, said that two accidents which had occurred while the chauffeur was driving the car were caused through the car being defective. Both before the first accident and after it witness explained to defendant's wife that his people did not accept any responsibility on regard to the supply of chauffeurs. A notification to this effect was also on their notepaper. It was the custom of the trade to accept no responsibility when sending out a chauffeur.

In re-examination, witness said that when a chauffeur was supplied to customers the man was always under the control of the customers, and so it would be unreasonable to expect those who supplied him to be responsible for any negligence on his part, if there were any.

Digitized by Google

The defendant stated that he bought the motor-car in question last October, and understood that it was new a few months previously. The chauffeur sent was incompetent, and he could not rectify most simple things in the arrangement of the gear. On one occasion the chauffeur ran into a stationary tramcar, apparently omitting to put on the brakes.

In cross-examination, defendant denied that when on the car he had told the chauffeur when to drive slowly, or given such instructions.

Mr. Charles R. Andrews, manager to the Paddington Motor Company, said it was a recognised custom of the trade that no responsibility should be taken by a firm in regard to the acts of a driver sent out by them.

Mr. F. Partridge, manager to the Holland Park Motor Company, Notting Hill, agreed with the last witness as to the custom of the trade.

John Barker, chauffeur, referred to above, stated that he was twenty years of age. He had duly served his apprenticeship and had driven all types of cars, altogether some 50,000 miles or more. There was no "governor" on the defendant's car, and the "clutch" was very "fierce." The accidents occurred in consequence of the brakes being defective.

The judge found in favour of the plaintiffs on the claim. With regard to the counterclaim, his Honour said he was not satisfied that there was a custom of the trade to the effect that firms sending out drivers did not hold themselves responsible for what might happen while the driver was working the car. The onus was upon the plaintiffs to prove the custom, but his Honour thought they had failed to do so. The contract was to supply a competent driver, but his Honour came to the conclusion that although the man was not absolutely incompetent he was not thoroughly competent, and in one or two respects it appeared that the driver was negligent. On the counterclaim there would be judgment for the defendant for £29 5s. 6d., with costs on both sides.

MOTOR v. HORSE TRACTION.

In a recent issue we gave the testimony of a user of a Foden steam wagon as to the economy it had effected over the horse traction formerly employed. We are now able to give exact figures of the economy a five-ton Yorkshire steam wagon has shown in the service of Messrs. Bellamy Brothers, Limited, mineral water manufacturers, Grimsby, as compared with horses.

This firm report that the wagon, doing thirty-five to forty-five miles per day, with full loads, will do the work of eight horses (working in pairs) on one ton of coké per week. They have found the relative weekly cost of each, in their work, runs out as follows :—

HORSES.

	£.	s.	d.
8 horses—Keeping, Shoeing, etc.	5	12	0
2 Drivers at 25s.	2	10	0
2 Youths at 12s.	1	4	0
	£9	6	0

MOTOR.

	£	s.	d.
1 ton Coke	0	10	0
Oil, etc.	0	3	0
1 Driver	1	5	0
1 Salesman	1	5	0
1 Youth	0	12	0
	£3	15	0

Messrs. Bellamy add that the horses doing country work can only work on alternate days, and that thus one driver requires four horses, whilst the motor, having proper attention, is ready every morning. As to interest on cost and depreciation after twelve months' experience with the motor-wagon they find it greatly in favour of the latter.

WARRANT ISSUED.

At the Alfreton Police-court, Frederick Holborough, of Sheffield, has been charged with negligently driving a motor-car at Alfreton on February 20th. Henry Stoppard, of Somercotes, said he was driving a horse and van in Alfreton on the evening in question about seven. The defendant was standing for a short time and afterwards started his car, which ran into plaintiff's vehicle, breaking both shafts. Witness asked the man for his name and address, but he drove off as quickly as possible. In the excitement witness did not take his number, but fortunately he got it from a constable who had seen the defendant pass through another portion of the town. Holborough did not appear, and the question arose in the minds of the magistrates as to the identity of the defendant. In the end they adjourned the case for a fortnight, and ordered a warrant to be issued for the arrest of the man.

CASE DISMISSED.

On Wednesday the Earl of Wicklow appeared at Mortlake to answer a charge under the Motor Car Act of last year of driving a motor-car at an alleged speed of 22½ miles at Castlenau, Barnes, on February 27th. Mr. Staplee rth appeared for the defendant and the case was dismissed.

MOTOR-CAR CONSTRUCTION.

At a meeting of the Cleveland Institution of Engineers, held at Middlesbrough on Monday, Mr. Arthur M. Hall read an interesting paper on "Motor-Car Construction." The author gave at some length the early history of the motor-car, stating that the French considered Cugnot with his steam carriage the inventor, while the English would look upon Trevithick, the Cornishman, and the right hand man of Boulton and Watt, as the inventor. But for fifty years after their day little was done, until several Englishmen, among them Gurney, Somers, Ogle, Hancock and Stone, constructed steam passenger coaches with which they were able to run considerable distances and practically without breakdown. Gurney's carriage averaged fourteen miles per hour, Somers' and Ogle's thirty-five, and Hancock's twenty-four. But further progress was stopped in 1832, when the House of Commons passed a law requiring that a man with a red flag during the day and a red lamp at night should precede every motor-vehicle at a distance of 100 yards. Little more was heard of motor-cars till about 1873, when Leon Bollée constructed his first steam car, which attained a maximum speed of twenty-four miles per hour, and weighed 3½ tons. De Dion, Serpollet and others followed with steam carriages, with which they attained satisfactory results; but it was not till 1889 that the first internal combustion engine was applied to automobiles under the patents of Daimler and also Benz. In 1894 Panhard and Levassor commenced the manufacture of motor-cars with petrol motors, which they constructed under the Daimler patent. Their first cars embodied many features which have since been almost universally adopted by other makers, among them being motor in front of the car under bonnet, cone friction clutch, variable meshing gears, differential and chain drive.

The petrol engine as used in motor-cars was almost universally of the four-cycle type, the four strokes of the piston comprising the cycle being suction, compression, explosion, and exhaust. The cylinders were generally of hard cast iron, the water jacket, ports, and valves being all cast in one piece. During 1902 and 1903 many prominent makers built their cylinders by casting the water jacket, ports and valve chambers in one piece of aluminium, and screwing into the casting a steel cylinder for the piston to work in. That had not fulfilled expectations. The unequal expansion of the different metals and the difficulty of keeping the water joints tight had prevented its general adoption. It was found difficult to lubricate the cylinder, and it was stated the steel walls of the cylinder set up more friction than cast iron.

The author then described and detailed the recent improvements that had been made in the various parts of the motor-car, particularly the valves, flywheels, piston, clutch, carburettors, transmission gear, brakes, control, etc. With regard to the future of the motor-car, Mr. Hall said that a first-class one was as reliable as the best type of locomotive on our British railways, but, like all other pieces of mechanism, material and workmanship must be paid for. Any one who wanted one cheap would buy an inferior article and spend many an hour on the road doing repairs. The very reliability and automatic action of a motor-car was a source of many of the troubles met with by careless users; it was quite easy to run a car all day and not look at its mechanism, but that could not be continued every day. If the average motor-car received a quarter of the attention which a good locomotive received or that a man would devote to his horse, much less trouble would result. The motor-car was more economical, notwithstanding its cost; it was more reliable and obedient to the driver, quicker and more comfortable. Although its use was extending considerably every day, it was only the social side of motoring that had made much progress, the commercial side—that of road haulage and delivery of goods—was almost untouched. When those who are interested in heavy haulage begin to appreciate the advantage and economy of motor-haulage on roads the industry will receive great impetus.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to The Editorial Department, Motor-Car Journal, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

The Editors do not hold themselves responsible for the opinions expressed by their correspondents, or for statements and facts which do not appear in the editorial columns.

The Editors and Publishers beg also to state that they will accept no responsibility for unsolicited contributions, even if used, unless payment for same is directly specified in forwarding, and the terms arranged before publication.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, APRIL 2, 1904. [No. 265.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

AS already announced, the application of the Winchester city authorities to restrict the speed of automobiles passing through the area of their jurisdiction to ten miles an hour has been the subject of an enquiry by the Local Government Board. After the representatives of the A.C.G.B.I. had given evidence, three magistrates testified to the absence of any real reason for such a restriction—Colonel Willan, chairman of the Southampton County Bench; Colonel Stratton Bates, a J.P. of forty-one years' standing; and Alderman Scott Foster, of Portsmouth, the latter of whom said that his borough had streets quite as narrow as Winchester, and tram lines as well. There had been no motor prosecution in Portsmouth for more than a year. Among other witnesses was the proprietor of the George Hotel, who said that he had forty to fifty motoring visitors a week, and would undoubtedly lose their custom if the ten miles limit were imposed. The report of the Local Government Board on the subject will be sent to the Winchester Council in due course.

An End-to-End Run.

MR. DOUGLAS WHITEHEAD'S motor-car run from John o' Groat's to Land's End on a 10-h.p. Argyll car has attracted considerable attention. Starting at 8.15 on the morning of Thursday, the 24th ult., he arrived at Glasgow shortly after midnight, crossing the border at 5 o'clock on Friday morning. The party reached Kendal at 8 a.m., and Warrington at 11.20. The weather changed as they proceeded southwards and heavy rain threatened, but there were only occasional sleet squalls, not affecting the roads. The car arrived at Bristol at 6.50 p.m. on Friday, having covered 700 miles in 34 hours 35 minutes. Here relays of petrol were not ready, the car being two hours before its time. Thus there was a delay of an hour and a half. This was in part atoned for by an excellent run to Okehampton, near which place the driver missed his way in the dark, went several miles astray, and finally pulled up in a churchyard. Turning back, the party reached the village and found that everybody was in bed. They knocked at several houses, but, getting no response, had to sleep in their seats. Resuming the run after three hours and a half, and taking local guidance, they arrived at Bodmin, stopped 58 minutes for breakfast, and pushed on to Land's End, which was reached at 12.50—making an end-to-end run of 52 hours and 35 minutes, and beating the record held by Mr. J. W. Stocks by nearly ten hours. The time actually spent in running was 45 hours and 3 minutes, lowering the record by 3 hrs. 10 min.

Difficulties of Non-stop Runs.

THE attempt to make an absolute non-stop run had to be abandoned on the first day, closed gates at level crossings being insuperable difficulties. Then, again, droves of sheep twice compelled a halt. The drivers had no sleep for two nights, and food and drink were taken under some difficulty. Mr. Whitehead was relieved in driving by Mr. R. Carlisle. The Hozier Company may be congratulated on the successful run of their car over a route of 927½ miles.

An Ex-Coachman's Views.

THE correspondence on drivers is getting personal, and "One with the Times" gives a hint which must not be overlooked. He compares the personal appearance of the groom and the mechanic, and apparently pays heed to the importance of the collar. This is a point that many mechanics overlook; it is a small one—and one that should not be neglected. Probably this ex-coachman's letter will bring some other motor drivers into the fray.

The Motor Volunteers.

SEVERAL members of the Motor Volunteer Corps have been engaged on a tour of inspection under the General Officer commanding Eastern District, visiting Brentwood, Bently, Kelvedon, Hatch and Ongar, etc., Messrs. E. E. Bentall, W. Bloomfield, C. Knight, and F. Sinclair being prominent in this connection. Mr. J. P. Dean has driven from Warminster to Southampton, and from thence he drove the Quartermaster-General Southern District to Lyndhurst, Romsey, and Botley in connection with a Staff ride. Mr. Harvey Dixon drove from Emsworth to Southampton, and thence drove the General Officer commanding Southern District to Beaulieu, Brockenhurst, Lyndhurst, and back to Southampton, on a Staff ride, on the 9th ult. Captain and Adjutant G. Skeffington Smyth has rejoined the corps from leave of absence, and resumed his duties with this useful auxiliary to the military forces of the country.

Motorists on Local Authorities.

BY securing election to local authorities motorists can do much to assist the movement, as was evident from some remarks which fell from the lips of the President of the East Surrey Club at the meeting of that body on Saturday. Major Foster said he was now a member of the Highways Committee of the Surrey County Council, and he considered it the blue ribbon of the Council. He asked all the members to let him know if they came across any bad pieces of main road, when he would at once bring the matter before the highway surveyor. Such an invitation should be readily responded to.

The Motor May Day.

THE May Day Parade of Motor Delivery Vans under the auspices of the Motor Van and Wagon Users' Association, to which we made reference last week, will take place on the afternoon of Saturday, the 30th inst. Should the Commissioner of Police assent to the proposal it will probably be held on the Thames Embankment, London, at 3 p.m., and only good weather will then be required to make the venture a thorough success. The work of organising the Parade will be no light task, but Mr. Basil Joy, the Technical Secretary of the A.C.G.B.I., who will be responsible, may be expected to have everything in perfect order and to make the event run as smoothly as the vehicles themselves.

Digitized by Google

The object of the parade is to encourage the drivers of heavy vehicles to pay careful attention to them with a view to the reduction of wear and tear and the cost of up-keep. Prizes to the amount of £50 will be given to the drivers for the best kept vehicle, and, up to the present, very favourable replies have been received to a circular letter which has been sent out to van owners who, even if they are unable to take part, have been good enough to wish the Automobile Club every success in its enterprise.

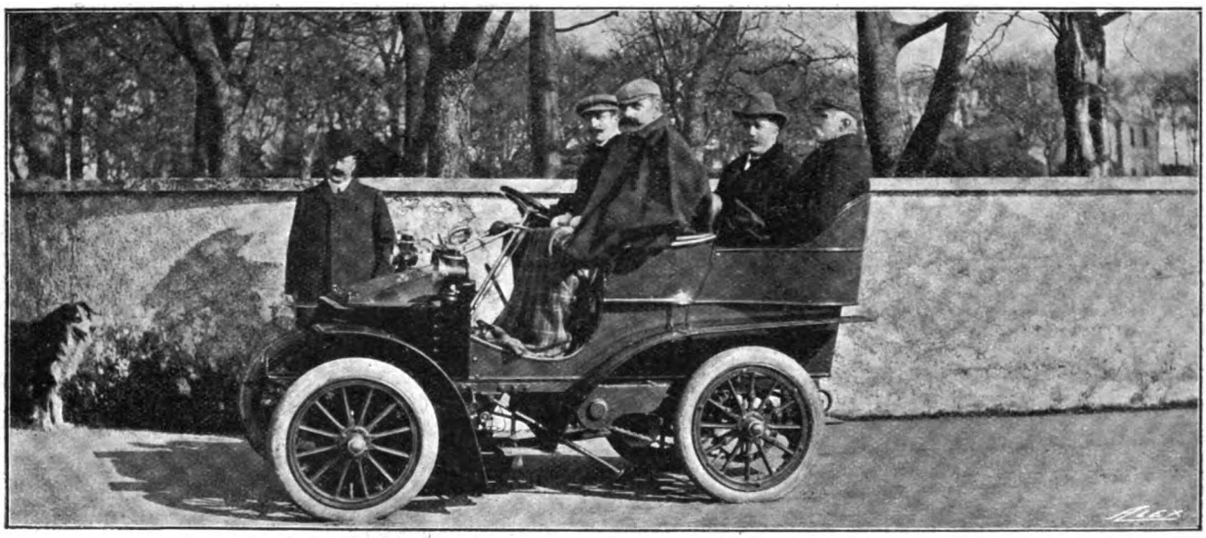
Lamps.

ACETYLENE lamps are a source of worry as well as of illumination, and many are the devices made to obviate their disadvantages. Many of these were shown at the recent Exhibition, and some of the inventions in this direction were nearly perfect. Some discussion on the subject of acetylene lamps has lately arisen in fire brigade circles, and advocates have come forth to defend the old plan of filling a lamp with pieces of camphor, pouring oil into it, and using the wick. The idea will probably be tried by some of our readers using paraffin lights, and their experience might provide some useful reading. We believe the tendency of such a plan is to hasten the charring of the wick; otherwise a clearer and whiter light is obtained. In connection with acetylene lamps, it is often found that some solid particles will pass with the gas to the burner, resulting in clogging it. To obviate this, a small piece of sponge placed at the outlet of the reservoir where the gas emerges will be found useful; this soaks up the moisture and likewise acts as a purifier, with most beneficial results, as only dry gas can then pass to the burner.

◆ ◆ ◆



Motorists as Robbers.

FREQUENTLY have we told of the assistance rendered to the police by motorists who have placed their cars at the disposal of the limbs of the law for the pursuit and capture of evil doers. At Widnes the tables have been turned, and investigations in connection with a recent highway robbery in that district seem to indicate that the outrage just committed was the work of a well-organised gang—just the same as that which was responsible for an unelucidated daylight robbery some months since. In the latter instance strong suspicions were attached to a motor-car which was seen in the village at about the time when the robbery was committed. In the present case the trap containing the assailants was preceded along the roads leading to Rainhill by an automobile, to which it is believed the booty was transferred. Strength is lent to the supposition that the two conveyances were in league with one another by the fact that at the later stage of the journey—during which the assailants frequently changed their attire—the driver of the trap was seen to be wearing a motorist's cap. It has also been ascertained that a strange motor-car, which the police have so far been unable to trace, was seen in Lymm on the same evening as that when the horse and trap used by the thieves were stolen.

◆ ◆ ◆

Motoring Law for Bombay.

IN the Bombay Legislative Council, a Bill to regulate the use of motor-cars in the Presidency has been introduced, and in moving the second reading Mr. Fulton said it had been decided that it was not desirable to prescribe any definite limit of speed. What they did prohibit in the Bill was reckless driving, and they reserved to the Government power to make rules limiting the speed at which motor-cars could be driven in particular places if it should be found necessary. It would, perhaps, be needful to lay down a limit of speed on the Ghauts on the way to Mahableshwar, and there were certain crowded streets of Bombay in which he thought it might be necessary to put notices regarding speed, but such regulations would have to be worked out by degrees. The Bill proposed to make rules for the numbering of cars in the same way as was being done in England. They proposed to prohibit public motor-cars from being let or from plying for hire in any particular roads except with Government permits. With regard to the granting of monopolies it had been decided that in the first instance none should be given to any company. They would see after two or three years if public competition was sufficient to provide an efficient service of cars. If it were, the question of a monopoly would not be revived, otherwise they might encourage some company by offering them the exclusive rights for a limited number of years.

The Lieut.-Governor, the Chief of the Police, and the Chairman of the Highway Board surveying the Eliminating Course in the Isle of Man. Mr. Julian Orde, Secretary of the A.C.G.B.I., at the wheel. (*See page* 95.)

◆ ◆ ◆

Feeders to Railways.

SOME time ago Sir Wilfrid Lawson, who is chairman of the Maryport and Carlisle Railway Company, referred to motor-cars as likely feeders to railway companies. Mr. J. Dixon, of Maryport, has lately urged him to bring before his co-directors the advisability of establishing a motor-car or a motor-'bus service between Allonby and Silloth. This he has promised to do, and Mr. Carr, the manager of the company, is, we believe, sympathetic to the idea. All over the country the railway directors are beginning to recognise the necessity of assisting the travelling public by the provision of such

Digitized by Google

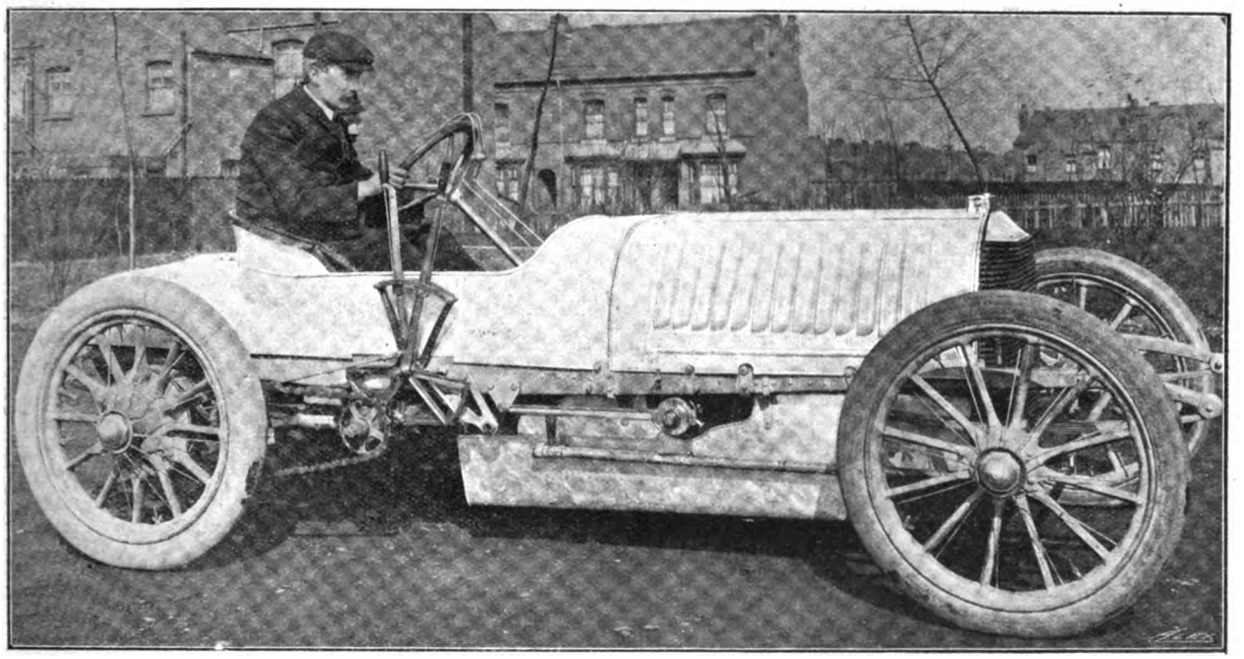
services. We shall be glad to hear of similar enterprises by smaller railway companies elsewhere.

◆ ◆ ◆

Police Zeal too Zealous.

THE superlative character of the zeal shown by the police in some localities in the enforcement of the Motor-Car Act is really too pathetic. At the Woolwich Police Court a young gentleman, living at Chislehurst was summoned by the police for driving a motor-cycle on the highway at Eltham, and failing to produce his licence when demanded by the police. The defendant pleaded guilty, but said there were extenuating circumstances. He started to drive to London, and running short of petrol he took the cycle to a shop for a further supply. He saw another motor there and asked whether he might try it. Without knowing that the numbers were not on he took it for a short spin, but he had not gone far before he met the constable, who asked to see his licence, which he had naturally left in the saddle of his own machine. Mr. Baggally (to the constable).—Did he tell you this? The Constable.—Yes. Mr. Baggally.—Why did you not tell me this? "It makes all the difference. A man may accidentally leave his season ticket at home; but that is altogether different to the case of a man who travels on the railway without a ticket. This is the sort of thing that makes people so angry with the police. The defendant not producing his licence is accounted for, and the summons is dismissed." We would congratulate the magistrate, Mr. Baggally, on his display of judicial common sense—a quality which might well be extended beyond Woolwich.

◆ ◆ ◆



Motor Parties.

BOTH at the Exhibition and since the closing of its doors we have received requests from people living in the north of London asking if we are organising any Motor Parties this summer—a development of journalistic enterprise in which we do not propose to embark. But the fact that such applications have been made testifies to the good influence of the Show in inciting public interest in motoring. Throughout the past fortnight cars have been so freely seen in the district that the curiosity for motor-car rides is undoubted, and any firm that would start a regular series of day trips from the northern suburbs to Windsor, the Garden City, Buckinghamshire, and other districts in that direction should find profit as well as pleasure in the scheme.

◆ ◆ ◆

Electricity and Automobilism.

BEFORE the eastern section of the Scottish Club, Mr. R. W. Hogarth has been lecturing on the electrical associations of automobilism. He reviewed three leading aspects of the subject, viz., the use of electricity as a means of igniting the explosive mixture in petrol cars, the electrically propelled motor-car, and the combined petrol-electric car. In dealing with the first, the respective merits of the battery and induction coil method and the magneto machine were discussed. A preference was expressed for accumulators over primary batteries as a source of energy for the induction coil method, and the author believed that many failures of ignition apparatus in the past had been due solely to slipshod work, particularly in regard to details of wiring and terminals, &c. He was also of opinion that the magneto method would shortly oust the battery system, since the sparking was much more powerful and regular, and moreover the system lent itself better to the multi-cylinder engines now being made. The latest Simms high-tension magneto was shown, this being a very compact apparatus which can easily be applied to any car. In regard to electric motor-cars these of course were driven by energy supplied by accumulators carried on the cars, which accumulators had to be recharged after a comparatively short run. They were both heavy and costly to maintain, and although great improvements in accumulator detail had recently been made the author did not think much advance would be made in this type of motor-car until some radical improvement in accumulators was effected. The combination of a petrol engine and dynamo with driving by electric motor had been experimentally tried and promised well, although at first sight the method might appear to be a very roundabout one. The method gave all the well-known advantages of electrical driving and control, and if, as seemed probable, the petrol turbine could be made a practical machine, there appeared to be a future for the combination. There certainly was room for improvement in efficiency of all the types of cars. In steam-driven cars it was computed that the efficiency as expressed in the ratio between the energy contained in the fuel burnt and the energy utilised at

The Welseley 72 h.p. Gordon Bennett Racer. (*See page* 95.)

Digitized by Google

the tyre was less than 4 per cent., in petrol driven cars about 6 per cent. or 7 per cent., and in electrically driven motor-cars (accumulators being originally charged by steam driven dynamos) the total efficiency on the same basis was about 4 per cent.

◆ ◆ ◆

Slow Progress in Ireland.

Now and again news of the Pirrie-Iveagh motor transport scheme filters across the Irish Sea, and, apparently, matters are moving slowly. A special meeting of the Galway County Council has been held for the purpose of considering the proposal of Lord Iveagh to establish a motor-car service for the conveyance of live stock and merchandise between Galway and Costelloe, in Connemara. The promoters desired that before entering on the enterprise the roads leading from Galway to the place of destination should be put in thorough order, so as to meet the requirements of the Local Government Inspector. The Council decided to afford every facility for the purpose, even to the extent of expending a couple of thousand pounds on the roads if necessary. The Urban Council at their meeting also gave permission to have the roads in their jurisdiction used for motor traffic. Local authorities are thus assisting the movement; why do not the central movers in the scheme travel more rapidly in the matter?

◆ ◆ ◆

Excitement in Singapore.

EXCITEMENT is great among the rikisha pullers of Singapore at the advent of the motor-car, and one of these gentry with his Chinese fare had a startling time in the High Street a few weeks ago. The rikisha was proceeding along the thoroughfare at the usual leisurely pace, when, it is alleged, a motor-car dashed into it. The passenger described a double somersault in the air and landed on his feet; the puller disappeared beneath the remains of his vehicle, which was smashed, and when he came to his senses he began picking up the fragments so that none might remain. In time he had an armful of firewood, which represented his rikisha. The Chinese passenger was too amazed to say or do anything. The motor-car, according to spectators, was uninjured.

◆ ◆ ◆

Lights on Vehicles.

THE L.N.W. RAILWAY COMPANY have a service of huge horse-drawn lorries running between Berkhamsted and Chesham, and during the past winter there have been several narrow escapes from accident brought about by these lorries carrying no tail lamps. The matter was taken up by one of the Committee of the Hertfordshire Automobile Club, and as a result of his correspondence with the Company, these vehicles are now furnished with very efficient red tail lamps. It is due to the railway authorities to say that their attitude with regard to the matter has been eminently reasonable, and that they have shown a prompt and praiseworthy regard for the rights and safety of other road-users. The Club may congratulate itself on its success in this matter, which may rightly be regarded as establishing an important principle.

◆ ◆ ◆

Steam Carriages.

FROM Messrs. Longmans, Green and Company we have received a copy of Mr. William Fletcher's new book on English and American Steam Carriages and Traction Engines. This is not the first volume Mr. Fletcher has written on the subject, but is practically a continuation of the same author's work on Steam Locomotives on Common Roads, published three years ago. Mr. Fletcher was a contributor on the subject to "Industries" from 1886 till the time it was practically merged into the *Motor-Car Journal*, and is as familiar with the subject as anybody who has written upon steam carriages. The work is divided into a dozen chapters, and includes sections devoted to self-contained passenger coaches, modern steam carriages, modern road locomotives, and traction engines, as well as road locomotives and trains for passengers and goods. The value of its 400 pages is enhanced by some 250 illustrations, including all the modern types of traction engines with which we are now familiar on the road. To those who have followed the history of this interesting branch of automobilism, Mr. Fletcher's work will be of undoubted interest and value.

◆ ◆ ◆

1905.

BEFORE the last of the cars had departed from the Agricultural Hall sufficient spaces had been let for next year's exhibition to warrant the prediction of continued success for this annual series of motor-car shows. The plan and prospectus is now ready, and several firms who were late in inquiring for stands at the Exhibition just closed have decided to book spaces without delay to avoid disappointment for 1905.

◆ ◆ ◆

To Advertisers.

A CORRESPONDENT, who apparently finds our advertisement columns of considerable interest, makes a suggestion which we commend to those gentlemen in the habit of using our small advertisement pages to make known their wants, whether in the way of cars or of drivers. He suggests that advertisers should use the name of their county when inviting replies to be addressed to a box number. The advantage of such a plan would be that drivers seeking situations would have some idea of the district with which they were concerned, while those on the look-out for cars would learn equally well, without actually identifying the seller, where the vehicle was to be found. It is a matter, however, in which no hard and fast lines can be suggested, but probably our advertisement columns may shortly show that some enterprising advertisers have taken the hint.

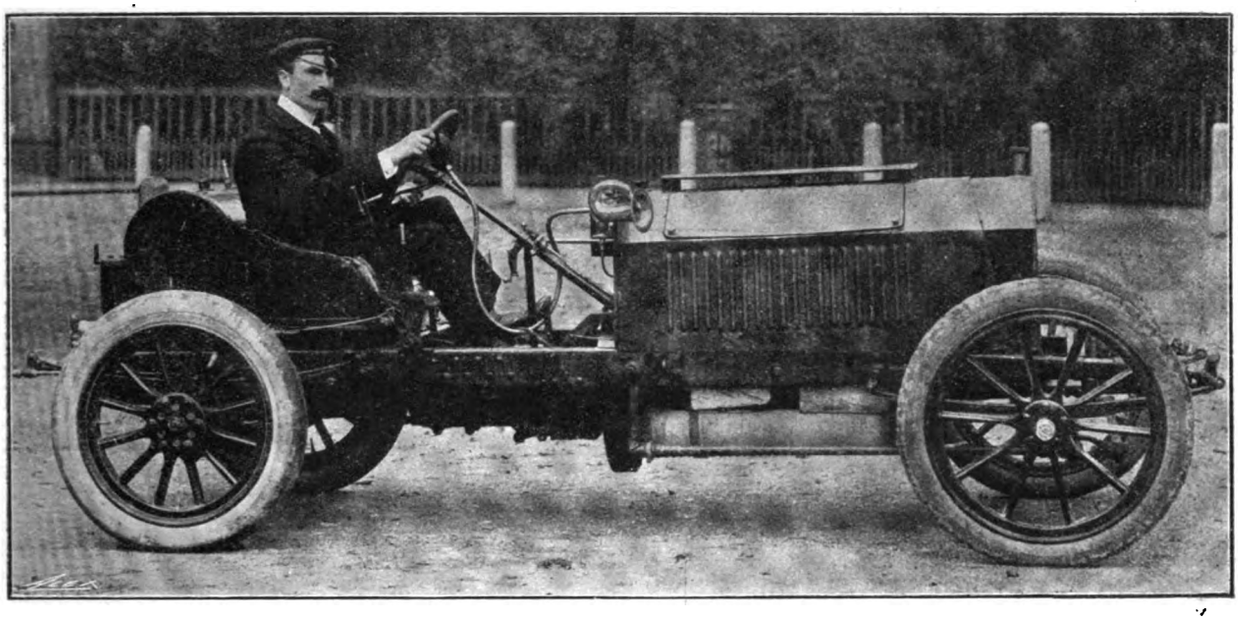
◆ ◆ ◆

Club News.

ON Saturday next, the 9th inst., the Yorkshire Club will commence the season with a run to Aberford, and on the succeeding Saturdays in April meets will be aranged to Ilkley, Doncaster, and Boroughbridge respectively. The Hertfordshire Club held its inaugural run last Saturday, starting from St. Albans, and, after a stop at Hatfield, proceeded to Hertford, and thence to Stevenage. From the latter place a return was made to the Red Lion Hotel at Hatfield, where tea was served. About thirty members took part in the event, and a most enjoyable afternoon was spent. Yet another item of club news comes from Preston, where it has been decided to form an Automobile Club, with Mr. J. Todd as president, Mr. Charles Wilding as secretary, and Mr. Humphreys as treasurer. Hardly a week now passes when we do not hear of the formation of an automobile association in some part of the country or other, and it is evident that these local clubs are forming an important factor in the automobile education of the public.

A RECENT distinguished addition to the ranks of motorists in Mexico is Sr. Ramon Corral, the Minister of the Interior, who has acquired a Winton 20-h.p. car.

THE new catalogue issued by Messrs. A. W. Gamage, Limited, extends to seventy-two large pages and will be found handy book of reference to motorists generally.



THE value of the foreign motor-cars imported into Germany during last year is returned at £253,750, as compared with £177,700 in 1902. By far the largest imports were of French origin.

A NEW feature of intercollegiate sport in America is likely to be introduced this year in a speed contest between the universities of Pennsylvania, Harvard, Yale and Princeton, all four having flourishing automobile clubs.

Digitized by Google

GORDON BENNETT RACE NOTES.

THE accompanying illustration shows Mr. S. F. Edge on his Napier 1904 Gordon Bennett racer—a four-cylinder car with the usual type of Napier engine. Of 80-h.p., the motor is extraordinarily light, its weight being only about 500 lbs. The engine differs from that of Colonel Mark Mayhew's by having multiple port suction valves atmospherically operated instead of mechanically, as Mr. Edge considers that in a four-cylinder racing engine one gets more life from the atmospheric valve. The motor is of course fitted with the Napier high-tension synchronised ignition. Every effort has been made to ensure that the car shall start and stop very quickly. It has three speeds forward and one reverse, and metal-to-metal clutch, exceedingly long springs, a steel frame tapered at both ends, with the springs carried right outside to the frame. On top speed the drive is direct from the engine to the live back axle. Mr. Edge informs us that the engine is exceedingly flexible, enabling the car to run from twenty to eighty miles per hour on the top speed without changing speed. The road wheels are 34 in. in diameter, shod with 120 mm. tyres on the back and 90 mm. on the front. The weight of the complete car is 963 kilos, so that it is well under the permitted weight.

Mr. S. F. Edge on his 80-h.p. Four-Cylinder Napier Racer.

WE are also able to illustrate on page 93 the 72-h.p. racer which has been entered by the Wolseley Company for the British eliminating trials in connection with the Gordon Bennett contest. The main dimensions are:—Wheel base, 8 ft. 7 in.; track, 4 ft. 6 in.; rear wheels, 36 in. diameter and 5 in. tyres; front wheels, 24 in. diameter and 3½ in. tyres. The motor has four cylinders of the horizontal type; it is suspended in the frame immediately below and in front of the dashboard, and is in such a position that the *mecanicien* may be able to make adjustments whilst travelling. It is fed by an equalising carburettor of special design, one jet supplying the four cylinders. The flywheel is of extra large diameter and the motor can be very rapidly accelerated. The radiator consists of a nest of tubes encircled by the water tank, placed in front of the car, with a fan working immediately behind it, driven from the motor by means of gearing. The gear box is suspended from three points, and is provided with four speeds forward and one reverse. All the gear shafts run on ball bearings. Both front and back axles are of I section steel, and the wheels are of the artillery type reinforced with wire spokes to take the side strains. The steering pillar is placed at an angle of 35 degrees, the ignition and throttle levers being brought into a very convenient position for the driver. The body takes the form of a very low boat-shaped hood extending from front to back. Louvres are provided in the bonnet to assist in cooling the motor. The petrol and oil supplies and pressure gauges are all placed so that the *mecanicien* has them constantly under observation, the commutator especially being placed so that it can be got at without trouble. Both foot and hand brakes act on the back wheels, the foot brakes being of the Wolseley special internal expansion type, the hand brake operating bands working on drums which are part of the chain wheel castings. In its road trials this car has proved itself very reliable, the chief features being its stability and easy running at high speed. Owing to the low centre of gravity obtained by the arrangement of the mechanism it has been found possible to take corners at a very high rate of speed.

◆ ◆ ◆

MR. RAWLINSON and Mr. Girling have been motoring in the Isle of Man during the last few days, and with other well-known motorists will become well acquainted with the proposed route before May 10th—the date of the Eliminating Contest. Meanwhile Mr. Orde has been on the island actively engaged in making preliminary arrangements for the trials; he has gone over the proposed route with the Governor and Deemster Kneen, and has met the members of the Highway Board, whose workmen are making repairs to the roads where needed as rapidly as possible. Mr. Orde made his headquarters at the Peveril Hotel, Douglas. It is proposed to have the starting point on the Quarter Bridge Road, between Woodlands and Bray Hill. The competitors will go southwards over Richmond Hill and through Ballasalla; they will pass King William's College and go along the Victoria Road, avoiding the narrow and busier streets of Castletown. Thence the route turns northwards to Foxdale, Ballacraine, Glen Helen, Creg Willey's Hill, Michael, Ballaugh, and Sulby, to Ramsey. Turning homewards, the route, instead of being taken by way of Laxey, will be by the new mountain road over Park Llewellyn and the shoulder of Snaefell, and down the hill past Creg-na-baa to the starting point. It is considered that this amended route has several advantages over that originally fixed upon. The cars will have to ascend Richmond Hill and Creg Willey's Hill instead of descending them. On the other hand, they will have a rather steep down grade from Snaefell. The greatest advantage of the route is, however, that it will avoid in the most convenient manner going through Ramsey, Laxey, and Onchan, where the possibility of danger, and the establishment of "controls," might militate against the success of the race.

Digitized by Google

There is very little difference in the mileage of the amended and the former route.

◆ ◆ ◆

ANNOUNCEMENT is made that Mr. Joseph Tracy will be the driver for the entry of the Peerless Motor Car Company in the Cup race. Mr. Tracy, who drove the old Cup racer a mile over the Ormonde Beach in 45 2-5 seconds, will drive a car in the A.C.A. elimination trials, and, if selected, will start for Europe early enough to familiarize himself with the course. The Peerless Company is building three machines for the trials, and beside Mr. Tracy, Mr. L. P. Mooers will, it is said, again try his hand at speed work. The car which works the best will be sent to Germany in charge of Mr. Tracy.

◆ ◆ ◆

THE engines of the racing cars which the Opel Company are building for the German eliminating trials will have four separate cylinders, the crank shaft having altogether five bearings.

◆ ◆ ◆

THE Villiers Hotel Company have taken the Drill Hall, in Douglas, for the storage of the cars of guests who will be staying at the hotel during the contest.

MESSRS. LEGROS AND KNOWLES, LIMITED, has been registered with a capital of £20,000 to carry on the business of manufacturers of motor-cars, etc.

THE British Automobile Commercial Syndicate, Limited, have been appointed sole agents for the "Hotchkiss" cars, which attracted so much attention at the Exhibition last week.

THE North British Rubber Company, Limited, have issued a new art catalogue of india-rubber motoring clothing, etc. Special attention may be called to the calendered coats mentioned on the first page, and to the envelope motoring rugs.

HIS EXCELLENCY SIR REGINALD TALBOT, Governor of Victoria, has just placed an order with the British Automobile Commercial Syndicate for a 16-h.p. F.I.A.T. and also a 20-h.p. Talbot. The two cars are to have bodies fitted to them by Messrs. J. Rothschild et Fils.

MR. JUSTICE KEKEWICH was engaged for two days last week in hearing an action to enforce an agreement made on June 4th, 1903, between the plaintiff, Mr. M. S. Napier, and the defendant, Mr. Charles Jarrott. In the end there was judgment for the plaintiff.

The Gordon Bennett Course.—The first important Curve near Saalburg.

A DAIRY farmer of Swaythling has, in the Southampton County Court, obtained £22 1s. 6d., "damages and expenses caused by defendants or their servants negligently driving their motor engine and running into a cow belonging to the plaintiff, and causing such injuries that the said cow had to be slaughtered."

THE ARROL-JOHNSTON MOTOR LORRY.

THE accompanying illustration shows a petrol motor lorry built by the Mo-Car Syndicate, Limited, for Mr. Robertson, of the Stonefield Laundry, Paisley. This gentleman, we believe, is the first to run motor-lorries for laundry purposes in Scotland, and his experience has been most successful. The vehicle is fitted with one of the Mo-Car standard 12-h.p. motors running at a normal speed of 800 revolutions per minute. Four speeds forward and a reverse are available, enabling a load of three tons to be carried at a speed of about

nine miles per hour, and a load of 30 cwts. at about twelve miles per hour. The drive from the engine to gear box, and from the latter to the differential countershaft, is by Renold silent chains, and thence by the usual side chains to the rear road wheels. Two brakes are provided, one acting on the gear shaft and countershaft, and the other an internal metal to metal brake on the inside of the hind wheels. Adjustable non-reversible wheel steering, with extra long double-threaded screws and ball bearings to prevent back lash, is provided. The Mo-Car Syndicate, which have now supplied three separate laundry companies with motor-vehicles with marked success in each case, are building lorries to carry loads up to six tons.

USE your car considerately and it will return the favour in improved and lengthened service.

WE learn that King Edward has just placed an order for one of the latest type of 28-36-h.p. Daimler motor-cars. A few weeks ago the Prince of Wales ordered a vehicle of the same type.

AMONG frequent visitors to the Exhibition just concluded was Mr. Oliver Stanton, wearing a scarf pin lately presented to him by the Prince of Wales as a souvenir of the introduction of His Royal Highness to automobilism by Mr. Stanton.

THE motor-car drivers at San Francisco have recently formed the Automobile Chauffeurs of California. The object of the association is stated to be "to protect automobile owners and dealers." Each man entering the association will be subjected to an examination and furnished with a certificate specifying exactly what car he is able to manage, and none other.

AT a recent meeting of the Florida East Coast Automobile Association it was decided that next year the races on the Ormonde-Daytona Beach will be all invitation events, and an increased entrance fee will be charged. New timing clocks are to be purchased, which will time every mile of a long race, and thus render possible records at intermediate distances. The dates for next winter's meet will be between January 17th and February 6th.

Digitized by Google

CONTINENTAL NOTES.

ARRANGEMENTS for the French eliminating trials are being rapidly completed. Every precaution will be observed to ensure that no accidents occur to the public. The roads through villages and sharp turns will be oiled, and both sides of the streets through the villages will be railed off, with protected passages at every 55 yards, permitting the crossing of traffic. Two trumpeters will be stationed at the entrance of each village to announce the approach of every car. M. Tampier, the time-keeper of the A.C.F., has estimated that there will be 15 kilometres of road treated with oil, and 35,000 metres of fencing erected along the course. The general public will be restricted to the fields adjoining the course, and an official will be placed at intervals of 110 yards on either side of the entire course. There will probably be two neutralised portions, viz., at Bethel and Vouziers, and in addition five stops of one minute each, viz., at the sharp turn at Chemery, the cross roads at Flize, and the level-crossings at Ballay, Novy, and Pont du Chesne.

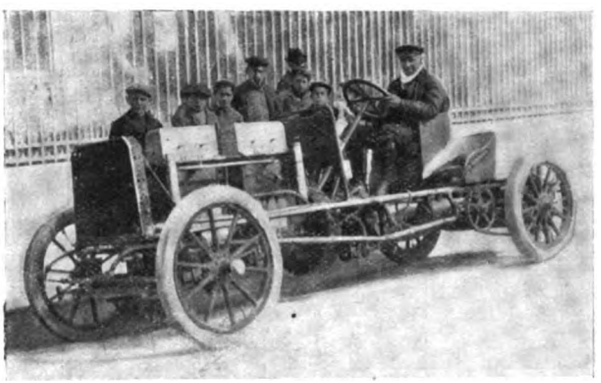
◆ ◆ ◆

THE automobile fetes at Nice commenced on Tuesday of last week by a touring competition with a run to San-Dalmazzo-di-Tenda and back, via Vintimille, Mentone, and La Turbie. Out of thirty-one entries twenty-one started, and of these nineteen finished, the first home being M. Parran on a 40-h.p. Berliet car. The competition was continued on Wednesday, the 23rd ult. The outward route to Saint Tropez was via Cannes and Sainte-Maxime, the return journey being through Le Luc, Le Muy, and l'Esterel. Nineteen cars started, of which eighteen finished. During the run a hill-climbing competition with a standing start and a stopping finish was held over a two-kilometre course on a stiff part of l'Esterel. The best time was made by M. Giraud on a 40-h.p. two-seated C.G.V. car (3 min. 4 1-5 sec.). M. Coste on a 30-h.p. three-seated Pilain was second in 3 min. 34 2-5 sec., M. Martini on a 16-h.p. two-seated Martini third in 3 min. 37 1-5 sec., M. Garin on a 16-h.p. Rochet-Schneider fourth in 3 min. 56 1-5 sec., Prince Lubecki on a 60-h.p. Mercedes fifth in 3 min. 57 sec., and M. Parran on a 40-h.p. Berliet sixth in 3 min. 59 2-5 sec. The programme on Thursday, the 24th ult., comprised a gymkhana, while on Friday a *rallye-papier*, or an automobile paper chase over a 60 kilometre course, was held. Owing to an unfortunate change in the weather the programme had to be altered, the flower fete being postponed until Monday, and the mile and kilometre trials until Thursday.

◆ ◆ ◆

THE Frankfort Exhibition, which closed on Sunday last, was the largest motor show so far held in Germany. Naturally native makers held the field as far as quantity was concerned, but French and Belgian makers did not hesitate to send some of their best products. The usual chain transmission was to be found on the majority of the cars, only a few have cardan joints; and of the latter the Benz-Parsifal cars were the most conspicuous. The stands of the Cannstatt Daimler and Opel concerns created great interest, as did also that of Messrs. Durkopp, who exhibited three and six-cylinder cars. The Martini cars were shown by Messrs. Deasy and Co., while among French cars the Clement-Talbot, Decauville, Gladiator, and Mors vehicles may be mentioned. Two-cycle motors were exhibited by Herr H. Soehnlein, of Wiesbaden, and Messrs. Koerting, of Koertingsdorf, near Hanover.

◆ ◆ ◆



THE French Association Générale Automobile is organising a practical scheme of examinations for motor-car drivers. A special committee has been appointed, with the Prince D'Arenberg as chairman, to draw up a provisional programme for these examinations, and to submit it to the Administration des Mines. In connection with the scheme it is proposed to establish a large instruction track on which lessons will be given and examinations held.

◆ ◆ ◆

AN International Cup is to be offered by the Motocycle Club de France for motor-bicycles under 50 kilogs., based upon the same lines as the Gordon Bennett Cup. The cup will be of the value of £80, and will be run for the first time in France in July next.

At the Starting Point of the Tourist Competition.

Duray on the New Gobron-Brillie Racer.

THE NICE AUTOMOBILE WEEK.

A TORPEDO boat, fitted with a petroleum motor, has just been launched at St. Petersburg. It is intended for the Russian navy, and is the first of its type.

◆ ◆ ◆

THE Automobile Club of Dordogne will hold a kilometre competition on the 15th of May near Perigueux.

◆ ◆ ◆

AN Automobile Technical Society has just been formed in Berlin, with Prof. Lutz, of Aix-la-Chapelle, as first president.

MR. CHAS. J. GLIDDEN, of Boston, U.S.A., has completed his itinerary for a proposed automobile tour of the world, and computes the distance at 20,000 miles. The entire route has been carefully outlined on maps of the countries to be visited. The roads of China, it may be mentioned, are narrow and totally unfit for motoring outside of Hong Kong, and the restrictions imposed by the Government make a drive of any extent impossible. Of unusual interest will be the drive in Spain, Portugal, Algeria, far into the desert of Sahara, in Palestine and India, skirting the Himalayas, under the feathery bamboo and bread fruit trees of Ceylon, on the islands of the East Indies and in the flowery kingdom of Japan. If time will permit and climatic conditions are favourable when in the locality, the Philippines will be included in the tour.

IMPROVEMENTS IN LUBRICATION METHODS.

THE earlier types of motor-cars were the subject of well-deserved criticism in regard to the very large and annoying escape of lubricating oil which frequently took place from their engines and gear cases, but it is a matter for congratulation that in modern vehicles this evil has been well-nigh eliminated. Among the causes which have led to this improvement are the substitution of force feed for gravity or capillary flow, the more complete enclosure of working parts, and the more careful fitting of cases. In the use of gravity cups, negligence in regard to stopping the flow when the vehicle was at rest frequently resulted in the feeding of an excess of oil, which usually found its way to the outside surfaces of the mechanism and thence to the road. On the other hand, with the force-feed system the flow of oil ceases with the stopping of the engine. In motor crank cases and gear boxes as now constructed, whether or not intended for splash lubrication, the greatest care is taken to secure oil tightness. The oil pockets in which the shafts have their bearings are frequently separated from the walls of the gear box by a space or channel through which the lubricant, after escaping from the outside end of the pocket, may return to the case instead of following the shaft to the outside air.

The Ormonde Side-Car.

Non-fluid greases furnished from compression cups are being applied for the lubrication of parts of the mechanism which hitherto were supposed to imperatively demand a fluid oil. Lubrication by grease is, remarks the "Horseless Age," not attended by any appreciable escape of the lubricant, and is very economical and perfectly efficient under all conditions within its range of usefulness. The oil in gear cases is much more efficiently applied than formerly, great pains being taken to distribute it over all parts of the bearing surfaces. Ring and chain oilers, drawing their supplies from oil pockets—devices which have been most successfully used in electrical and other machinery—are being applied freely in automobile practice.

MOTOR-CYCLING NEWS.

THE Easter tour of the Motor Cycling Club will be in the Shakespeare country, with headquarters at Dunchurch.

◆ ◆ ◆

THE opening run of the season of the Glasgow Motor-Cycle Club will be held on Monday next, the destination being Ayr.

◆ ◆ ◆

FORTY-FOUR entries have so far been received for the motor-cycle reliability trial from Paris to Bordeaux and back, which is being organised by the Auto-cycle Club de France. The entry list will be definitely closed on the 15th inst.

◆ ◆ ◆

MOTOR-CYCLISTS assembled in gratifying numbers at the Agricultural Hall, London, on the last day but one of the Exhibition, to hear a paper by Mr. Victor Hart, elaborating some suggestions previously made for the conduct of the motor-cycle Reliability Trials to be organised during the present year by the Auto-Cycle Club. Mr. Robert Todd presided, being supported by Mr. F. Straight, the Secretary of the Club, and several well-known members of the trade, as well as riders whose names are familiar to our readers. In the course of his paper Mr. Hart suggested that the west or north-west of London seemed to be the best situation for the starting point if clear of the suburbs; there are plenty of hills near Oxford, High Wycombe, Henley, etc., to fully test the power of the engines. If variety was desired in the routes, the south and south-west could be easily reached via Hampton Court Bridge, and kept clear of streets and greasy tramlines. He would limit distances to 100 miles a day, and start not earlier than 9 or 9.30 a.m., thus enabling the men to obtain their breakfasts in comfort. The convenience of the riders ought to be considered, for these trials were not a test of the endurance of the men, but of the machines. It was easy enough to talk of 150 to 200 miles in a day whilst the discussion took place in a comfortable room; those who were anxious for big distances in the day should try the effect themselves of only 100 miles per day for ten days in succession in a repetition of the fearful weather experienced in the last trials.

◆ ◆ ◆

HAVING discussed the means of checking riders, Mr. Hart went on to deal with marks for speed and cheapness. These he would omit altogether, but to ensure equality between varying size engines, two, three, or six classes, with a maximum cylinder capacity in each, might be made, starting at 68 mm. by 68 mm., and rising a few millimetres per class, with a final class of unlimited capacity provided the machine, as a fully-equipped roadster, did not exceed the weight limit to be fixed by the new Committee. A machine with multi-cylindered engine could enter in any class up to its capacity limit. Two-speed gears would be in evidence, and without experience of suitable conditions for hill tests, no rules ought to confine inventor's efforts. Perhaps the fixing of a minimum gear ratio of about 6 to 1 might get over the difficulty which caused the introduction of the speed tests in 1903. The sealing of parts should be carried out fully so that no part of the engine or details necessary to working of same or propulsion of machine could be touched without the eventual knowledge of the judges. Each maker should be limited to entering three machines.

◆ ◆ ◆

THE Local Government Board had practically created a new type of vehicle, viz., the three-wheel motor-cycle, weighing under 3 cwt. unladen. Their inclusion would not entail any extra expense for organisation; the same entry fee as for single machines, or not more than an addition of 25 per cent., would invite a number of entries, and the fees thus received would enable the organisers to spend money more freely than was possible with the limited amount at their disposal last year. No limit as to size of engine should be imposed; the passenger should be named and provided by the entrant, but carried upon another competitor's machine. In conclusion, Mr. Hart advocated the abolition of the section for private riders—a view that found considerable support in the subsequent discussion.

HERE AND THERE.

SIR JAMES BELL, of Kilmarnock, has just acquired a 12-h.p. Wolseley car.

AMONG the purchasers of cars at the Exhibition were the superintendent of the L. & N.W. Railway Works at Wolverton and the chief officer of the Chingford Fire Brigade.

THE net premiums received by the General Accident Assurance Corporation, Limited, last year amounted to £262,479. Mr. A. Nixon is manager of the company's motor department.

IN view of the demand for a two or three speed gear for motor-bicyles, Mr. Henry Sturmey has just patented both a two and a three speed gear for attachment to the crank shafts of bicycle motors.

AT the Cadena Works, Allen Street, Sheffield, Messrs. C Harlow and Company are making petrol and oil reservoir tank for fitting to the dashboard of cars, and are also specialising on similar work for motor-cycles.

MESSRS. PANHARD AND LEVASSOR have received an order for two large motor carriages from Lord Londonderry. One is a 24-h.p. with large body to seat eight, similar to that used by the Prince of Wales. The other is a 15-h.p. landau.

THE Continental Caoutchouc and Guttapercha Company have just published the 2nd Edition of the Automobile Guide for Germany. The book for 1904 is even more complete than the edition of 1903, and contains no less than 1,400 towns, with full particulars of petrol stations, repair places, garages, etc. The volume extends to over 900 pages, and is an indispensable guide to automobilists visiting Germany.

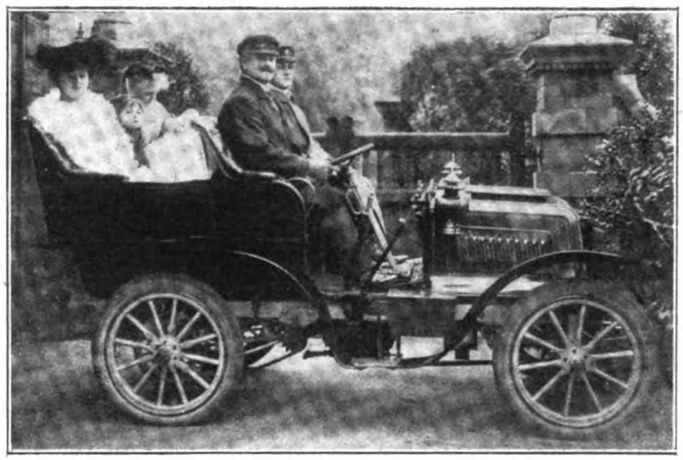
THE members of the Ladies' Automobile Club of Great Britain and Ireland were invited to visit the motor-car show at the Agricultural Hall, and many of the members were present with their friends at the reception given in the Automobile Club's rooms by Mr. and Mrs. Charles Cordingley and Miss Pursehouse. An orchestra played selections during the course of the afternoon, and tea was served.—*Morning Post.*

MR. W. D. VENNING has retired from the Motor-Car Industries Company, and in future the business will be carried on under the same title by Messrs. Ledbetter and Beazley as motor factors, repairers and dealer in all makes of steam and petrol cars. The firm have a well-equipped garage at 55, College Street, South Kensington, W., which is open night and day. A staff of competent drivers is also available, while a feature is now being made of hiring out petrol cars.

THE chairman of the touring committee of the American Automobile Association is arranging to accommodate 1,000 automobiles likely to take part in the run to the World's Fair at St. Louis in August next. He believes that fully this number will be stored in the grounds when the caravan reaches the Exhibition. New York motorists will leave on July 26th, the Boston section will leave on July 25th, and meet the New York delegation at Buffalo. The section from Buffalo will leave on July 26th and a Columbus division starts on August 4th. There will also be runs from Minneapolis, St. Paul, Denver, Omaha and Kansas City.

THE question as to whether Virginia Beach is to successfully rival Ormonde Beach, in Florida, as an automobile racecourse is still unsettled, notwithstanding the inspection trip made by a number of New York automobilists for the express purpose of deciding this point. Five powerful cars made short runs along the beach on the 13th ult., one getting up a speed of nearly 60 miles an hour for a short stretch. The sand was, however, wet and soft, its condition having been much impaired by a strong gale, and a real test was out of the question. It is expected that another trial will be made at a date not yet determined, when the weather is likely to be more propitious. A big Mercedes had a narrow escape from being buried in the quicksand. While running off the course the wheels sank deep into the sand, and only after a hard struggle did the car respond to the efforts of the party, who hauled it out with ropes.

THE Motor-Cycle Club of Denmark has just been formed in Copenhagen.



THE Velox Engineering and Autocar Company, Limited, has been registered with a capital of £2,000.

WITH the title "How to Choose a Motor-Car," Messrs. J. R. Richardson and Co., Limited, have just issued an interesting booklet descriptive of their 12-h.p. Richardson car.

A PUBLIC motor-car service has been started between Brunswick and Wendeburg. The vehicles used are 26 seated petrol 'buses built by Messrs. H. Bussing and Company, of Brunswick.

THE Warner Differential Gear Company, of Muncie, Ind., U.S.A., have sent us a booklet illustrating their spur differential gear for use on motor-cars, of which they make a speciality, and for which they are seeking an English agent.

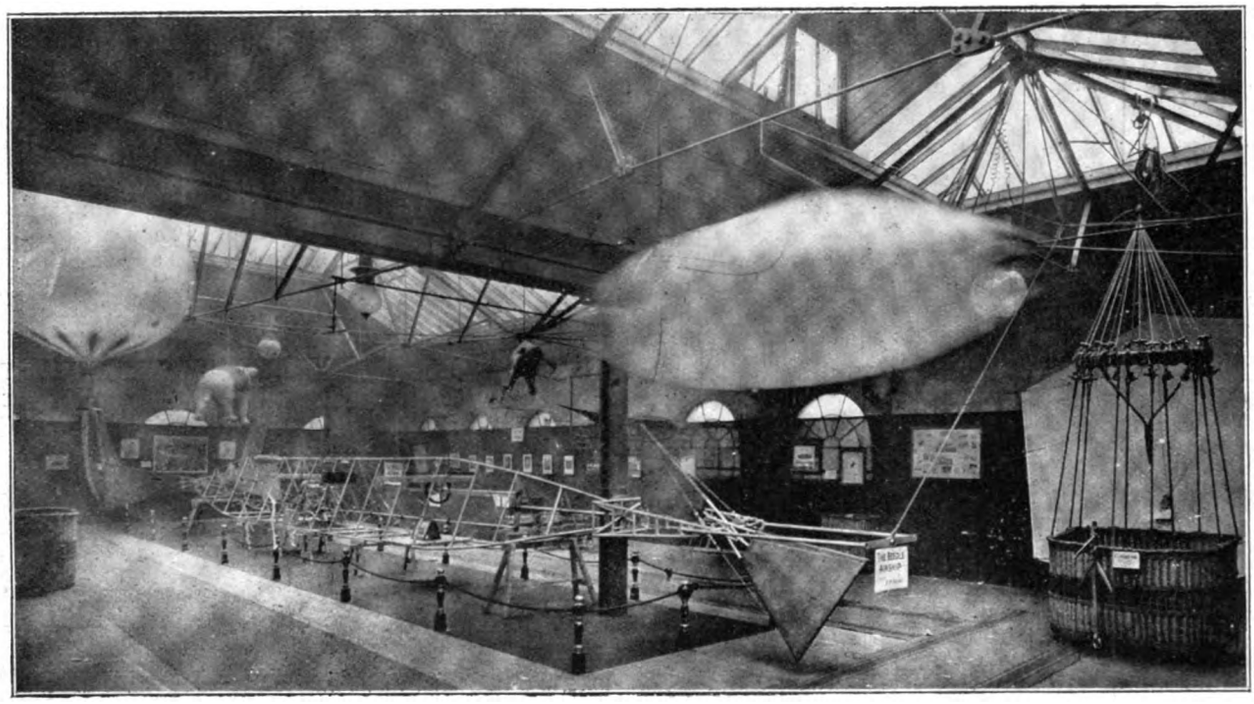
THE American National Association of Automobile Manufacturers having decided not to hold an endurance contest during the present year the prospects at present are that there will be few competitive events, other than track races, in the United States during the coming season.

Mr. and Mrs. Eugene Sandow with their two little Daughters and Nurse, on his 12-15-h.p. Argus car. The gentleman at the side of Mr. Sandow is Mr. Max Karminski.

A VERY interesting and useful handbook of the Triumph motor-cycles has been issued by the Triumph Cycle Company, Limited. The various parts of the machines are fully illustrated and described, while a number of pages are devoted to hints to users of this company's motor-cycles.

THE City Automobiles, Limited, has been registered with a capital of £10,000 to adopt an agreement between Messrs. R. Clegg and A. H. Salmon for the transfer of certain premises, and to carry on the business of motor-car stores, etc. The first directors are Messrs. E. Manville, J. M. Gorham, and E. A. Locock, and the registered office is at 34, Queen Street, E.C.

THE Clipper Tyre Company, Limited, has been registered with a capital of £65,100 to acquire and turn to account certain licences, agreements and privileges relating to the manufacture of pneumatic tyres with a view to adopt an agreement between the Clipper Pneumatic Tyre Company, Limited, of the one part, and Mr. W. S. Tinkler (as trustee for this company) of the other part.



THE Doherty Motor Accessories Company, Limited, has been registered with a capital of £5,000 to acquire the business now carried on by Messrs. W. H. Doherty, F. J. Page, J. Welch and J. Bayley at Trafalgar Works, Upper Well Street, Coventry, as the Doherty Motor Accessories Company, and to carry on the business of manufacturers of motor parts and accessories, etc. There will be no initial public issue. The first directors are Messrs. J. M. Fenton (chairman), W. H. Doherty, F. J. Page, J. Welch, and J. Bailey.

The Motor-Car Exhibition at the Agricultural Hall.

[SECOND NOTICE.]

[*Photo by* **General View of the Display by the Auto Club in the North Annexe.** *Argent Archer*]

THIS week we give the second instalment of our report of the Exhibition held last week at the Agricultural Hall. This proved an unqualified success, and the attendance of the trade and of actual motorists as well as of prospective owners of cars showed how well the organisation of the event had been previously thought out. In the Gallery business was as brisk as in the Main Hall, and the permanence of the display was assured by the re-bookings of space for next year's Show, which will take place from March 18th to the 25th, 1905.

Fig. 43.—The Decauville 14-h.p. Double Phaeton with Side Entrance.

PETROL CARS.

THE MOTOR CAR COMPANY, LIMITED, exhibited five complete Decauville cars and a *chassis* of the new 12-h.p. type, an illustration of which was given in a recent issue of the *Journal*. The various types of bodies fitted include a coupé and a Roi des Belges tonneau, as well as the standard pattern tonneau fitted to the 10-h.p. *chassis*. The 12-h.p. and 14-h.p. types embody all the latest Decauville improvements, including the fortified back axle and the metal shield which, securely bolted to the frame, affords additional support to the motor and protects the mechanism from mud, wet, or dust. All are fitted with the Decauville dynamo, by means of which the ignition accumulators are re-charged whilst the engine is running. The new 12-h.p. car is fitted with a four-cylinder engine, having cylinders 90 mm. diameter by 110 mm. stroke; the inlet as well as the exhaust valves are mechanically actuated. The centrifugal governor acts on the inlet, a pedal accelerator being fitted, by means of which the speed of the engine can be increased to 1,200 revolutions per minute. A combined

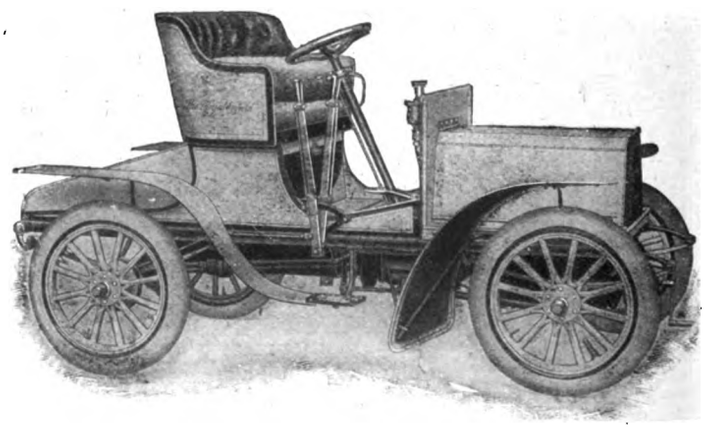

Fig. 44.—The Royal Enfield 6-h.p. Car. (*See page* 101.)

honeycomb radiator and tank is now employed in connection with the water circulation. The carburettor is of the automatic air regulation variety. Three speeds forward and a reverse are controlled by one lever, the drive on the top speed being direct, the power being transmitted through bevel gearing to a live axle. As usual in Decauville cars, the engine and gear are entirely protected, and the new model should prove as successful

Digitized by Google

as its forerunners. Fig. 43 shows the 14-h.p. side-entrance double phaeton, the *chassis* having a longer wheel base than usual. A novelty on the stand was an 8-h.p. petrol motor-tramcar capable of seating twelve persons.

The "Royal Enfield" cars made by the Enfield Cycle Company, Limited, were exhibited by MESSRS. GOY AND CO. We first inspected the 6-h.p. two-seated car, of which an illustration is given in Fig. 44. This has a tubular frame, in the fore part of which is set a 6-h.p. De Dion engine, cooled by means of a friction driven pump and a ribbed-pipe radiator set in a frame. The car is of the cardan shaft and live axle type, with three speeds forward and a reverse; on the top speed the drive is direct. The brakes are of the metal to metal expanding type, and both the hand and foot brakes are so arranged that on application the clutch is first disengaged. The car, which has a wheel base of 5 ft. 11 in., has accommodation for two persons, while a large amount of luggage can be carried at the rear. The Enfield Company are also now turning out a 10-h.p. car fitted with a two-cylinder engine of their own construction like the smaller car; this has a frame of tubular construction. The cylinders are 4 in. in diameter by 5 in. stroke, with inlet and exhaust valves operated mechanically off one cam shaft, Longuemare carburettor and centrifugal governor. The two cylinders and water-jacket are cast in one piece; the valve chambers are also an integral part of the cylinder, this construction ensuring reliability of running. The crank shaft gives large and ample wearing surface for the thrust bearings, and also for the connecting rod bearings. The fly-wheel is of large proportions, ensuring great regularity in the running of the engine. The latter is cooled by a gear-driven pump and honeycomb radiator. The tubular frame is carried on four springs slung so that they will give a comfortable suspension under the most trying conditions. The change-speed gear gives three speeds forward and one reverse, the drive on the top speed being direct. The foot brake acts directly on the transmission shaft from the change-speed gear. Several excellent arrangements have also been devised in other parts, while the comfortable tonneau should make the Royal Enfield a popular car for the 1904 season. Examples of the Royal Enfield 2¾-h.p. belt-driven and 2½-h.p. chain-driven motor-bicycles were also exhibited. Part of Messrs. Goy's stand was also devoted to a display of the well-known Lanchester cars, for which they are agents. Of special interest was an 18-h.p. water-cooled car with front bucket seats and a large double tonneau at the rear. The vehicle, which is fitted with an arrangement whereby the engine can be started from the seat, is claimed to be able to attain a speed of 55 miles per hour.

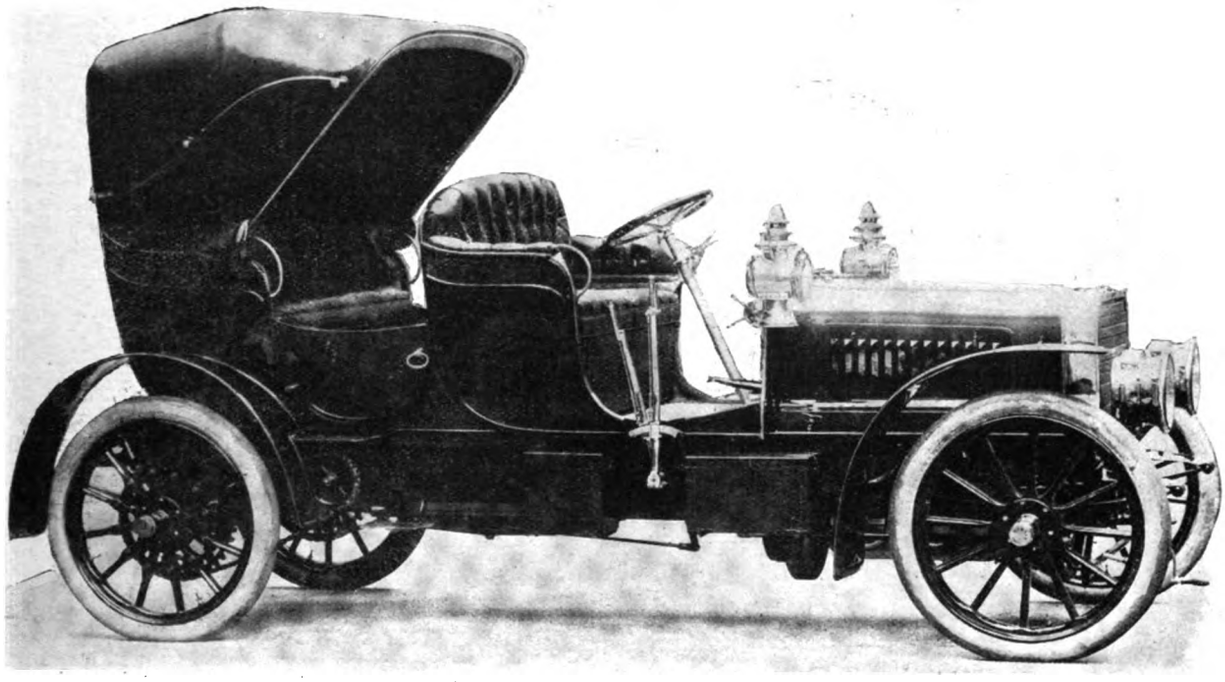

Fig. 45.—The "Herald" 24-h.p. Side-Entrance Double Phaeton.

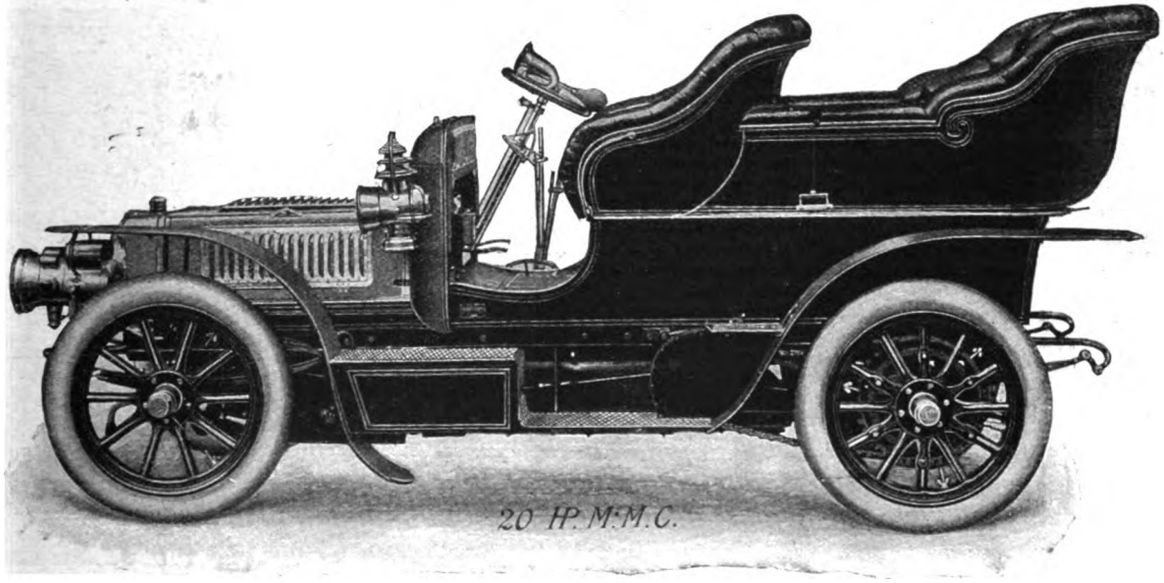

Fig. 46.—The 20-h.p. M.M.C. Roi des Belges Car with Side Entrance. (*See page* 102.)

In addition to the "Pelham" 6½-h.p. voiturette illustrated and described in a recent issue of the *Journal*, MESSRS. S. R. BAILEY AND LAMBERT, LIMITED, had on view two excellent examples of "Herald" cars, for which

Digitized by Google

they have secured the British agency. The first one we examined was a 12-h.p. car with wood and steel frame and double-cylinder engine. The water-circulation is maintained by a friction-driven pump and ribbed-pipe radiator set in a frame, a manometer being mounted on the dashboard to enable the driver to see that the water circulation is in proper order. The governor is adapted to act on a throttle valve; it can, however, be put out of action by an accelerator pedal. The clutch, which is of the leather-faced cone type, is so arranged that it can be dismounted without disturbing the gear box. Three speeds forward and a reverse are controlled by one lever. The gear is of the sliding type, and arranged somewhat on the lines of that adopted in the Mors cars, that is to say, the drive on the top speed

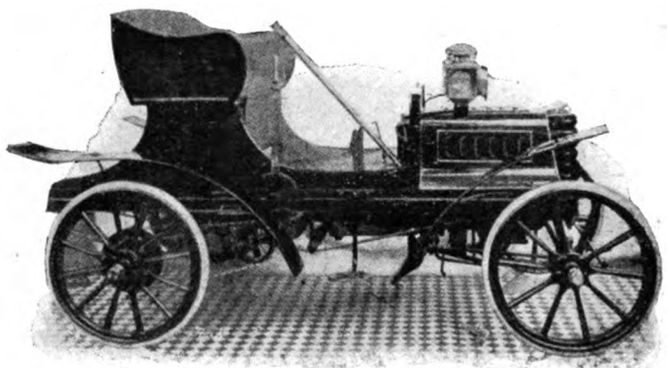

Fig. 47.—The "Thor" 6-h. . Two-seated Car.

is direct through a separate bevel gear to the differential shaft. The latter is connected to the rear road-wheels by Brampton roller chains. Special provision is made for lubrication, an oil reservoir, with pump, sight-feeds, and gauge glass, being fitted on the dashboard, leading to all important bearings. A pedal operates a metal-to-metal band brake on a drum fixed to the gear shaft, and a side hand lever actuates equalised band brakes on the rear road wheels, both brakes acting equally well either forwards or backwards. Fig. 45 depicts the handsome 24-h.p. side-entrance double phaeton "Herald" car exhibited on this stand. Except that the engine comprises four cylinders, and that four speeds are available, in addition to the reverse, the general details are similar to those of the 12-h.p. car. As will be seen, this vehicle has a very pleasing appearance, the finish, generally, being of a very high class.

The Motor Manufacturing Company, Limited, had a large stand, on which were exhibited well-finished examples of the M.M.C. 25-h.p., 20-h.p., 10-h.p., and 8-h.p. cars, all of which have been dealt with in recent issues of the *Journal*. A new addition to the latter is a mechanically-operated inlet valve and a governor, as a result of which the running of this vehicle has been made much quieter. Several new designs of bodies were shown fitted to the 8-h.p. *chassis*, these including a mail phaeton. A 20-h.p. car (Fig. 46) with Roi des Belges body, having entrance at the side, was another vehicle to which reference may be made. It was pleasing to find that the M.M.C. concern had two *chassis* on view, one of the 20-h.p. type and one of the 8-h.p. Both were excellent specimens, and attracted much attention on the part of visitors.

A new comer to the show was the "Thor" Motor-Car Company, of Leicester, which exhibited a two-seated car, the principal feature of which is the special arrangement of the springs on which the channel frame is supported. Altogether there are four springs—a transverse one at the front and another transverse and two side springs at the rear. They are all so connected to the frame as to so reduce the vibration that solid tyres may be used in place of pneumatics. The motive power is supplied by a Simms single-cylinder engine, giving 6-h.p. at 1,200 revolutions, and 8-h.p. at 1,600 revolutions per minute. The ignition is by Simms-Bosch magneto, controlled from the dashboard. Three speeds forward and a reverse are operated by one lever, the power being transmitted through a special friction clutch to the gear box, and thence by side chains to the rear road wheels. Metal to metal brakes are fitted, while the steering can either be by tiller, as illustrated in Fig. 47, or by wheel. The Thor Company are also builders of heavy artillery wheels, samples of which were to be seen at their stand.

In addition to their well-known "Traveller" voiturette, the Alldays and Onions Company, Limited, exhibited a new light car, of which an illustrated description was given in the *Journal* of the 19th ult. The motive power is supplied by a 7-h.p. single-cylinder engine with external fly-wheel and mechanically-operated valves. Two forwards speeds and reverse, with the direct drive on top gear, are provided, the power being transmitted by bevel gear on to a live axle. The standard car has seats for two persons, but one vehicle exhibited had accommodation for three, a separate seat being provided for the driver. An interesting display of their new pattern motor-cycles was also made. The 2½-h.p. engine is made throughout by Messrs. Alldays, and all parts are interchangeable. The frame is designed with special cradle for carrying the motor in an upright position. The tank has compartments for two accumulators, coil, lubricating oil, and sufficient petrol for 160 miles. A float register is provided for showing the quantity of petrol in the tank. The Alldays 5-h.p. "Traveller" voiturette, which has already been described in these columns, shows a few changes in detail, but is otherwise unaltered.

Messrs. Brown Brothers, Limited, had an interesting display of "Brown" cars, chief among which is the *chassis* of a new 8-h.p. car they are introducing to meet the demand for a relatively powerful car at a moderate price. The general arrangement is that of the standard bevel-gear driven type of car, but the workmanship appears to be of a high grade character. The motive power is supplied by a 8-h.p. vertical engine set in the fore part of a wood and steel frame. The water circulation is maintained by a gear-driven pump and honeycomb radiator; the motor is provided with a governor, which acts on a throttle valve on the inlet pipe. The engine and gear box are mounted on an auxiliary frame, the two being connected by an internal leather-faced clutch, so arranged that it may be disconnected without disturbing the gear box. The latter is of the usual sliding pinion type, giving three speeds forward and one reverse, the drive on the top gear being direct. The rear axle is well supported, while provision is made for lubricating the driving bevel pinion from the dashboard. The usual three brakes are provided, those on the hubs of the rear road wheels being of the expanding metal-to-metal type. On the same stand were also shown specimens of the "Brown" 8–10-h.p. double-cylinder standard cars, these being made either with side-chain or cardan shaft transmission, and of the "Brown" 12-h.p. cars. The latter have four-cylinder motors and chain drive, the various details, such as radiator, governing, etc., being of the approved pattern. On a separate stand Messrs. Brown Brothers had an extensive display of motor-car and cycle components and accessories to give even a list of which would more than fill a page of the *Journal*. Reference may, however, be made to the new "Motorite" belting for motor-bicycles, which is made of one piece of Balata canvas, wound into V shape, so that there are no joints or plies to come apart. It is also claimed to be unbreakable and unstretchable, the tensile strain being equal throughout the whole length.

At the stand of Autocars and Accessories, Limited, were displayed specimens of the 10-h.p. two-cylinder Minerva cars, built by La Société La Minerve, of Billancourt, near Paris, and a 12–16-h.p Clement car, constructed by the Clement-Gladiator Company, of which a description was given in our report of the Salon in December last. Interest at this stand was mainly centred on the working models of the Hitchon change-speed gear, the pinions of which are mounted on free-wheel clutches. The pairs of pinions are so arranged that there are always at least two pairs in mesh, the power being transmitted through the pair giving the higher gear. Thus, while the other pair is running it is doing no useful work, being overrun by the higher gear. As the speed is changed down by bringing the pinions of the lower gear already partly in mesh fully so, this takes up the drive. In this way the changing of gears is facilitated, as there is always a gear partly in mesh to take up the drive when necessary.

A novel form of double-purpose car was displayed by the Motor Carrier Syndicate, it having been designed for the use of tradesmen. For business purposes the rear part of the *chassis* can be fitted with a parcels chest capable of carrying a load of 6 cwt. The chest is made so that it can be quickly detached, and a seat wide enough for two persons fitted in

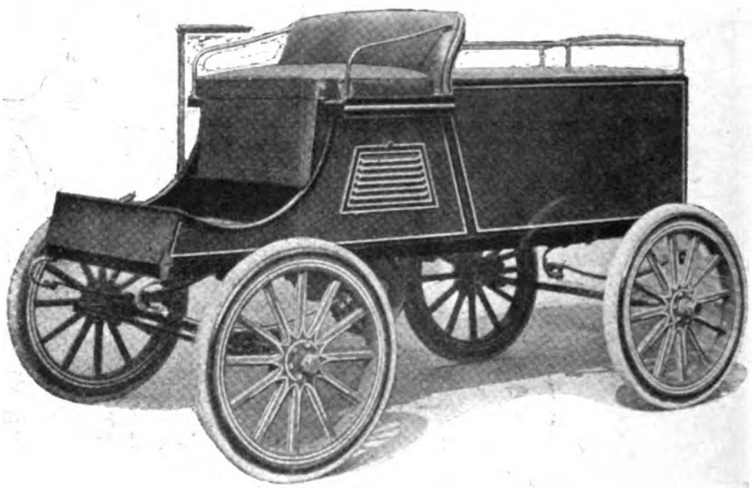

Fig. 48.—The 6-h.p. Motor Carrier.

its place, the vehicle then having the appearance of a double phaeton. The motive power is supplied by a 6-h.p. vertical engine located under the front seat. A carburettor is provided, which will, it is stated, work either with petrol or paraffin. Combined with the motor is a speed-reducing gear, the speed of the engine being reduced from 1,700 to 700 revolutions. On the slow-running shaft is a chain wheel, which transmits the power to a chain wheel forming part of an epicyclic gear on the rear axle. Two speeds forward and a reverse are available, the gear only being brought into use on the first and reverse speeds. The car, which weighs 7 cwt., is able to attain a speed of twenty miles per hour.

Digitized by Google

Messrs. O'Neil and Co., who have secured the British agency for the Corre cars, had a number of these vehicles on view. They are of French construction, and in many points closely resemble the Renault cars, the frames being of tubular construction. The largest car was of 16-h.p., fitted with Mutel or Aster four-cylinder motor with mechanically-operated inlet valves. The cooling is on the thermo-syphon system. Three speeds forward and a reverse are controlled by one lever, the drive on the top speed being direct through the cardan shaft on to the rear live axle. The brakes are all of the expanding band type. The 12-h.p. car (Fig. 49) is on similar lines throughout, except that the power is furnished by a De Dion double-cylinder engine, while the 9-h.p. car has a De Dion single-cylinder motor. The Corre cars are well known in France, having figured successfully in several of the races and competitions of recent years.

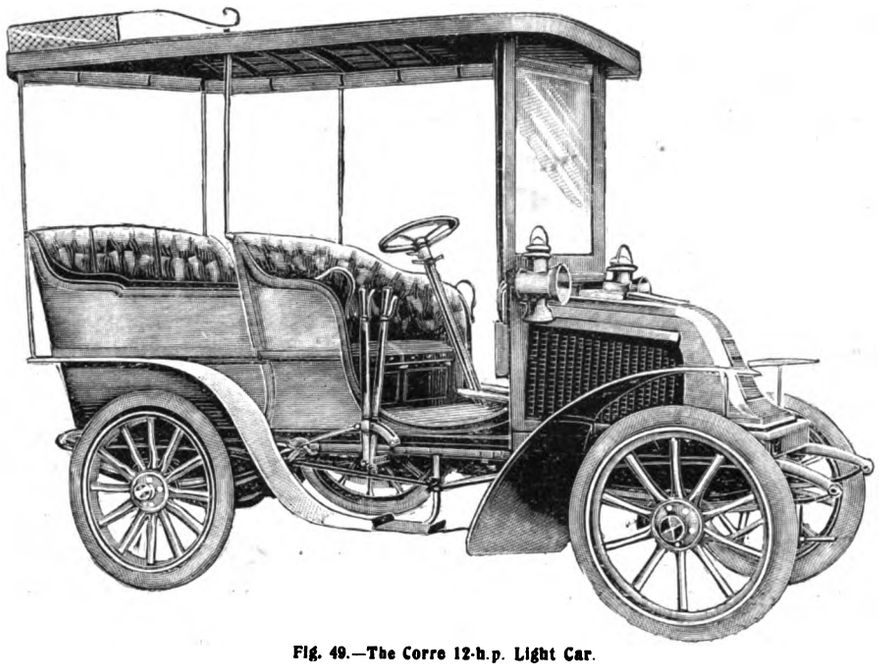

Fig. 49.—The Corre 12-h.p. Light Car.

The London General Automobile Company, Limited, confined their exhibit to a couple of well-finished examples of their 16-h.p. "Maxim" car, which, while possessing no striking departure, is on modern lines throughout. The frame is of pressed steel, in the forepart of which is set a double-cylinder engine having cylinders 110 mm. diameter by 120 mm. stroke, and developing 16-b.h.p. at a speed of 1,000 revolutions per minute. The inlet valves are mechanically-actuated, and are interchangeable with the exhaust valves. A special form of automatic carburettor is employed, this being so arranged as to give a correct mixture at all engine speeds. Three speeds forward and a reverse are provided, the transmission being by means of side chains. The plan adopted of hinging the carriage body at the back upon the frame allows of its being tilted up entirely, so as to expose all portions which may occasionally require adjustment. The Maxim cars are very wisely kept within moderate limits of gearing, so that frequent use of the speed lever is avoided, and the wear and tear of the gear lessened.

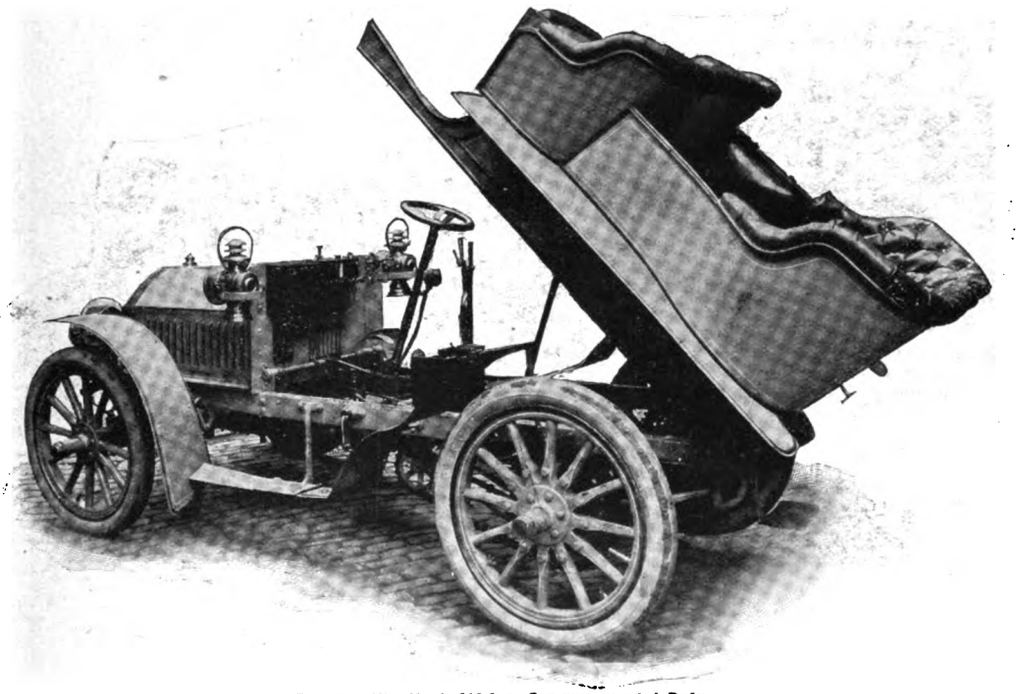

Fig. 50.—The Maxim 16-h.p. Car with hinged Body.

At the stand of the Automobile Components, Limited, a special point was made of the "Automotor" voiturette, fitted with a 4-h.p. single-cylinder motor. The transmission can be varied to meet the wishes of the prospective owner, being either by chain or from the engine to change-speed gear and back axle by single belt. The change-speed gear gives two speeds forward, steering being by means of an inclined hand wheel. The car is of simple design and extremely light, while its long wheel base is an important point to be noticed. A light car set for those contemplating going into the automobile trade was also on view, as well as the "Automotor" 10-h.p. *chassis* and the 10-h.p. car with tonneau body and bucket seats. The motor is a two-cylinder one, and is said to develop 14-h.p., the cylinder dimensions being 105 mm. by 125 mm. Various sets of car components and spare parts completed an interesting display.

Digitized by Google

The exhibit of MINERVA MOTORS, LIMITED, consisted of examples of the two, three, and four cylinder Minerva cars, of 10, 15, and 20-h.p. respectively. The general lines of construction follow the chain-driven type of car, the engine being identical except for the number of cylinders, each cylinder being entirely separate, with the inlet valves on one side and the exhausts on the other, both being mechanically actuated. The

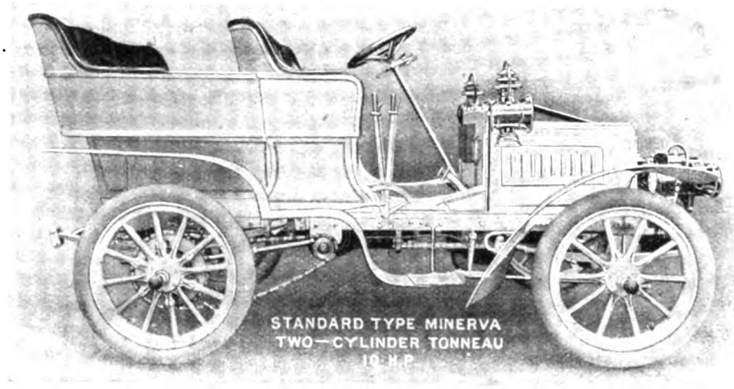

Fig. 51.—The Minerva 10-h.p. Car.

cylinders are 94 mm. bore by 114 mm. stroke, the normal speed being 1,200 revolutions per minute. The governor is adapted to act on the inlet, enabling the engine to be slowed down to 200 revolutions per minute. Three speeds and reverse on one lever are provided, with a direct drive on the top speed. The frame is of armoured hickory wood, reinforced at the corners, the engine and gear-box being carried on a steel underframe. The brake and clutch pedals are of the push-forward type. There are three brakes, one actuated by pedal to the countershaft, and the others by side lever to drums connected with the back wheels. Attached to the drum of the differential brake a ratchet ring is fastened, on to which a pawl is dropped to prevent the car running backwards down hill. Any type of body can, of course, be fitted to the *chassis*, Fig. 51 depicting a 10-h.p. standard tonneau. Without presenting any radical departure from modern practice, the Minerva cars merit the attention of those seeking reliable vehicles at moderate prices.

Three cars formed the exhibit of the CANTERBURY MOTOR COMPANY. The first of these was a neat little four-seated vehicle. This follows standard lines, being fitted with a 9-h.p. De Dion engine in front, and having three speeds forward and one reverse; the power is transmitted by bevel gear to the rear live axle. The 10-h.p. car (Fig. 52) while following the generally accepted lines, contains a few special features. The frame is built of wood and steel; the motor is a 10-h.p. double-cylinder Tony Huber with water circulation maintained by pump and framed ribbed-pipe radiator. Three speeds forward and one reverse are controlled by one lever. From the gear box the power is conveyed by a cardan shaft to the rear live axle. The clutch is of the internal cone type, and between it and the gear-box is a special coupling to enable the clutch to be taken out easily when necessary. The 20-h.p. Canterbury car has a stamped steel frame and four-cylinder engine, the latter having mechanically-operated inlet valves. The mixture is furnished by an automatic carburettor provided with a jacket, through which hot water may be circulated. The arms of the flywheel are made to act as a fan to draw a current of air through the radiator. Three speeds and a reverse with direct drive on the third are afforded by a gear box of the usual type, and which is connected with the rear axle by a cardan shaft. A feature of this car is found in the brakes, both the foot and hand brakes acting at the rear axle. Close to the hubs of each of the back wheels are two drums, inside which are expanding brakes, one operated by a pedal and the other by a hand lever, a compensating arrangement being provided in conjunction with each of the brakes.

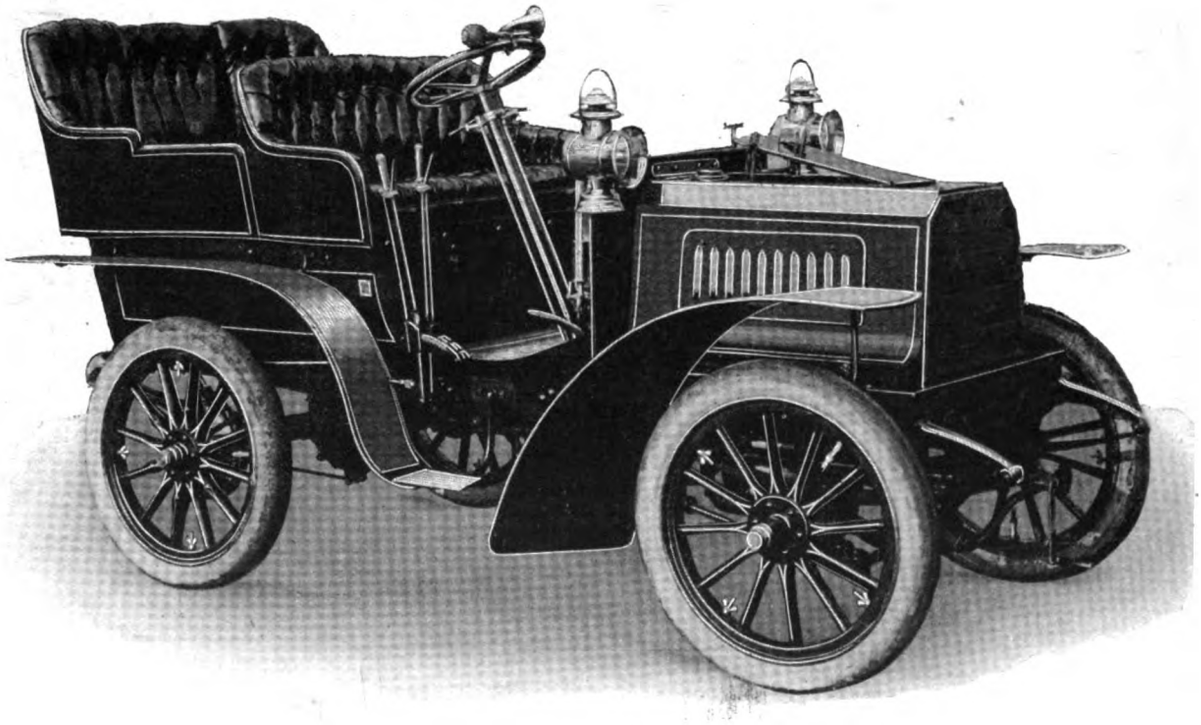

Fig. 52.—The Canterbury 10-h.p. Two-Cylinder Car.

MESSRS. HALL AND CO., of Tonbridge, had an extensive display of Darracq and Talbot cars. Of the Darracq vehicles examples of 8-h.p. single-cylinder, 12-h.p. double-cylinder, and 15-h.p. and 24-h.p. four-cylinder

Digitized by Google

vehicles could be inspected. Messrs. Hall and Co. also showed an 8-h.p. double-purpose car. This is provided with a detachable tonneau and a van body to carry 5 cwt. It is well adapted for tradesmen's purposes, as either body can be readily substituted for the other. Of the Talbot cars those on view range from 8 to 20-h.p., all being fitted with tonneau bodies.

A newcomer to the Show was the CORONET MOTOR COMPANY, LIMITED, whose exhibit was of a most interesting character. Two cars were exhibited, —a 16-h.p. four-cylinder vehicle, similar to that illustrated and described in the *Journal* of the 19th ult., and an 8-h.p. car with tonneau body. The latter has a frame of pressed steel, in the fore part of which is set a single-cylinder "Coronet" motor having a bore of 4⅜ in. and a stroke of 5½ in. A view of the engine is given in Fig. 53. The fly-wheels are inside the crank case, and are of good weight and properly proportioned. The valves are mechanically-operated by one cam shaft, which can be removed without splitting the cases. The cam shaft with its wheels and governor runs continuously in oil in a dust-proof case. The normal speed of the motor is 1,200 revolutions per minute, at which it develops 10-b.h.p. The ignition plug is screwed into the induction valve cover. Special attention has been devoted to the water-cooling of the cylinder, the water circulating round each valve seat, keeping the exhaust extremely cool. The weight of the motor complete, with carburettor, etc., is 175 lb. The power is transmitted through a leather-faced cone clutch to a gear box giving three speeds forward and a reverse. On the top speed the drive is direct. Although of the Panhard type, the sliding is done on round shafts, there being no square shafts or wheels sliding on feathers or keys—a depar-

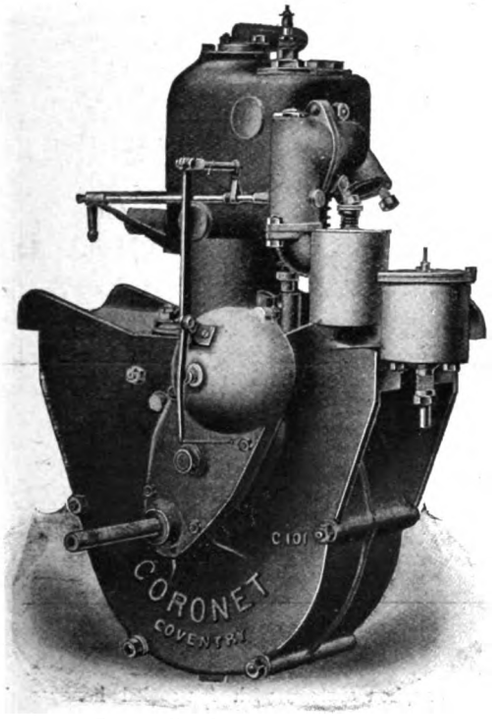

Fig. 53.—The Coronet 8-h.p. Motor.

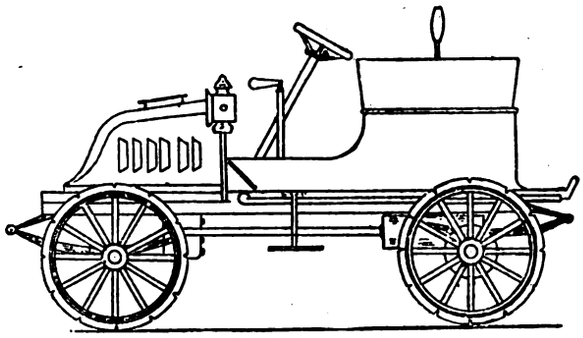
ture which the makers claim enables all parts to be accurately ground after hardening and ensures silent working on all speeds. A cardan shaft and bevel gear transmit the power to the rear live axle. The steering is the Coronet patent irreversible adjustable type, which provides against back lash after lengthy use. The car has a long wheel base, and the body, which is nicely upholstered in leather, provides ample seating accommodation for four persons. At this stand were also to be seen specimens of the "Coronet" 16-h.p. four-cylinder, 8-h.p. single-cylinder, and 3½-h.p. water-cooled and 3¼-h.p. air-cooled engines, the last two being designed for use on motor-cycles. These have mechanically-operated inlet valves, and we noticed that the gear wheels operating the cam shaft were marked, so that if taken apart they could be reset without difficulty. The Coronet Company have also introduced a new carburettor for engines up to 6-h.p., to which we shall probably refer in a later issue.

On the stand of M. H. Cintrat the GENERAL MOTOR-CAR COMPANY, LIMITED, exhibited one of their 6½-h.p. doctor's cars, fitted with hood and front glass screen. The motive power is supplied by a 6½-h.p. Aster engine, driving through a gear-box and cardan shaft on to a live axle. Three speeds and a reverse are available, while ample space is provided at the rear for carrying instruments, etc.

The novelty on the stand of MESSRS. R. REYNOLD JACKSON AND CO. was a 7-h.p. car (Fig. 54), which at its low price should soon become a popular type, especially in view of the fact that it seats four persons. The engine is set in the fore part of a tubular frame and drives through a clutch and cardan shaft to a gear box located close up to the rear axle, with which it is connected by bevel gearing. The constructional features of the gear box, which gives two speeds forward and a reverse, were illustrated and described in our issue of November 14th last, as was also the combined friction clutch and brake. The body, which is of the dog-cart pattern in natural wood, is particularly worthy of inspection, special attention having been devoted to the question of accessibility of the various parts of the mechanism. To this end the body is so fitted that it can be entirely removed in a space of about one minute, exposing the gear, back axle, driving shaft and engine; it can also as quickly be converted into a two-seated car, with spare



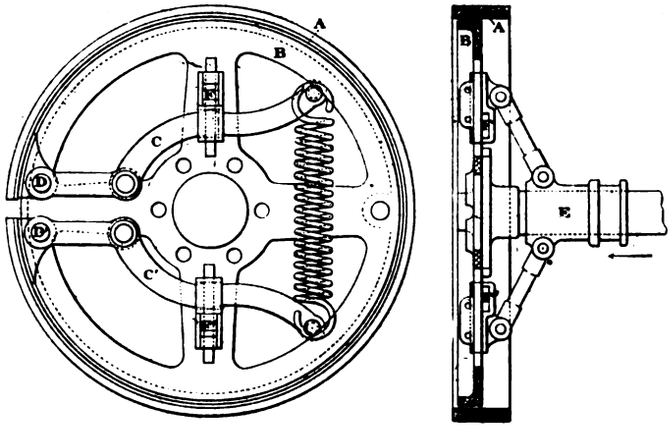


Fig. 54.—The Jackson Dog-Cart.

luggage room. The 3½-h.p. "Jackson" runabout was also on view, as also several examples of the "Jackson Tourist" cars, which have been improved in several details for the 1904 season. The engine is of the horizontal single-cylinder type of 8-h.p. and fitted with a heavy flywheel. The motor is coupled direct by means of a flange to the transmission gear, which gives two speeds forward and one reverse.

The BROUHOT MOTOR COMPANY OF GREAT BRITAIN, LIMITED, exhibited a *chassis*, a complete tonneau, and a 15-18-h.p. side-entrance double phaeton of the Brouhot type of vehicle, which are made in sizes ranging from 12 to 40-h.p. Dealing with the 15-18-h.p. car exhibited, the frame is being made sufficiently large to accommodate a body having side entrances. This is fitted with an engine, the four cylinders of which are cast in two pairs, the normal speed being 1,000 revolutions per minute. All the valves, both inlet and exhaust, are mechanically actuated off one cam shaft. The carburettor is Messrs. Brouhot's own design, and provides for the automatic regulation of the air in order to give the correct mixture at any or all speeds. The jet is also so arranged that it can instantly be taken out for cleaning purposes. Pump circulation is adopted in conjunction with a framed ribbed pipe cooler and tank, through which a current of air is drawn by a belt-driven fan. The crank chamber is divided into compartments, thus avoiding the fault that when climbing long hills the back cylinders get all the oil, whilst the front cylinders obtain but little, if any. The governor is adapted to act on a throttle valve, which when entirely closed opens a second valve to allow the engine to draw in cold air. An ingenious form of friction clutch is employed to connect the engine with the gear-box. It consists of a steel band, the outer surface of which is lined with camel-hair belting. The band itself is so arranged that it can be readily detached; it is expanded within the fly-wheel by means of two toggle levers. The countershaft brake is water-cooled, while those in drums on the rear wheels are practically identical in form and action with

Figs. 55 and 56.—Front and Sectional View of Brouhot Clutch.

the clutch. The transmission is by gears to a countershaft, and thence by side chains to the rear road wheels, with direct drive to countershaft on the top speed. The whole transmission is protected from dust and mud by an undercasing. The frame is of pressed steel or armoured wood. A feature of the Brouhot cars is the provision of a shock or vibration damper, so designed that whilst allowing the springs of the car to exert their full elasticity in ordinary work, it takes up and deadens any sudden shocks, such as are produced when the car is moving quickly over a bad

Digitized by Google

oad. The control is by a single sector in the middle of the steering wheel, and the flexibility of the motor is claimed to be such that it can be run at from 100 to 1,000 revolutions per minute.

A varied exhibition of petrol cars was made by the INTERNATIONAL MOTOR-CAR COMPANY, LIMITED, including a 12-h.p. two-cylinder Portland, a 12-h.p. Corre car with Aster motor, and a 10-h.p. Corre landaulette with double-cylinder De Dion engine. Chief interest at this stand was, however, centred on the *chassis* of the new "Diamant" cars the International Company are introducing into this country. They are of French construction, and are made in two sizes—12-h.p. and 24-h.p. Except that one car has a double cylinder engine and the other a four-cylinder, the following particulars may be taken as applying to both vehicles:—Commencing with the frame, this is of pressed nickel steel, narrowed at the front to allow the steering wheels to take a larger "lock" than usual. The motor and gear box are supported on a secondary frame. The 24-h.p. engine (Fig. 57) comprises four separate cylinders, 90 mm. bore by 130 mm. stroke. All the valves are mechanically operated off one cam shaft, the inlets being located in the cylinder heads and actuated by tappets. The water circulation is maintained by a gear-driven pump and a Loyal radiator. A governor is provided which controls the supply of mixture to the engine, the carburettor, which is on the lines of the Krebs, automatically regulating the quality of the gas in accordance with the speed of the motor. The ignition is by means of a gear-driven Simms-Bosch magneto. The base chamber of the motor is provided with detachable hand-hole covers, which enable the big ends of the piston rods to be inspected. The clutch is of the internal leather-faced cone type, and it is so connected up with the throttle valve that when withdrawn the speed of the engine is cut down. A joint is provided on the shaft between the clutch and gear box, enabling either to be readily dismounted without disturbing the other. Three forward speeds and a reverse are provided, the drive on the top being direct. The change-gear is operated by a simple rack and sector gear. The cardan shaft which connects the gear box with the rear axle is provided with special universal joints. A feature of the car is the provision made for preventing any undue strain on the back axle. All the brakes are of the metal-to-metal type, those connected with the rear wheels being of the internal expanding type.

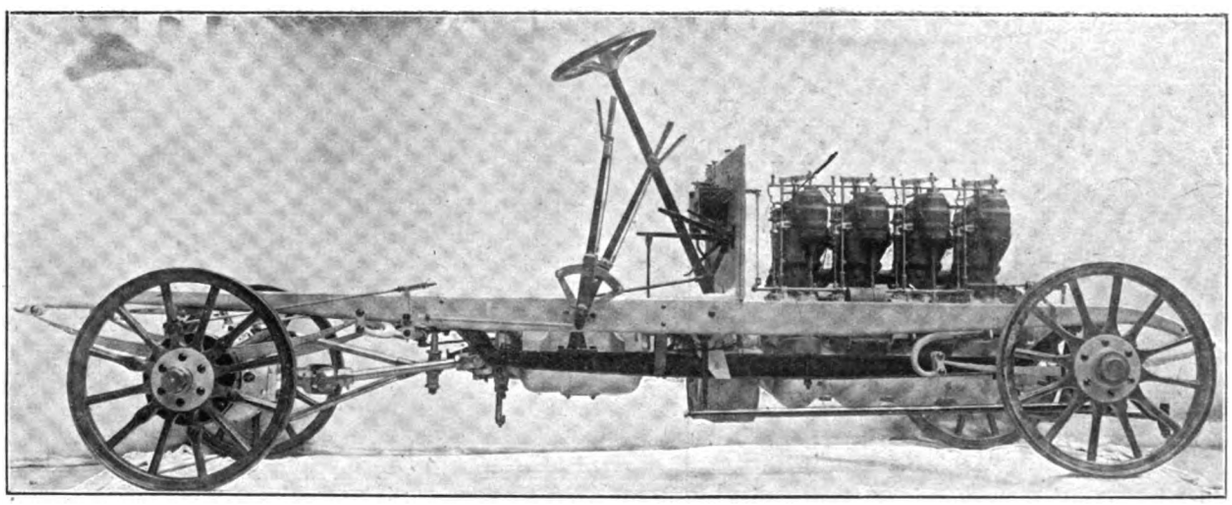

Fig. 57.—Chassis of 24-h p. "Diamant" Car.

The NORMAL POWDER AND AMMUNITION COMPANY, LIMITED, who have acquired the agency for the "Prunel" cars in this country, showed a number of these vehicles, all of which follow the standard lines of chain-driven cars. The 12-h.p. vehicle has a two-cylinder motor, three speeds and reverse, and a well-finished tonneau body. The 24-h.p. car on view was a more elaborate vehicle, having a long wheel base suitable for a side-entrance body. The motive power is supplied by a four-cylinder Mutel engine having mechanically-operated inlet valves and Xenia automatic carburettor. Four speeds forward and a reverse are provided. Considerable interest was shown in a 9-h.p. landaulette with De Dion engine and body work by Messrs. Holmes, of Derby, specially designed for doctors' use, one of the special fittings consisting of a folding wash-hand basin with both hot and cold water supply.

The stand of MESSRS. J. R. RICHARDSON AND CO., LIMITED, Lincoln, came in for a large amount of attention, due principally to the presence of the new Richardson 6½-h.p. two-seated car which has been introduced to meet the demand for a reliable vehicle at a moderate price. The motive power is supplied by a 6½-h.p. Aster engine, set in the fore part of a tubular frame. The power is transmitted through a clutch to the gear box, which gives three speeds forward, viz., 6, 18 and 28 miles per hour, and a reverse. Thence a cardan shaft transmits the power to the differential on the rear live axle. Three metal-to-metal brakes are fitted, one at the rear of the gear box, and two of the expanding type in drums connected to the rear wheels. The car has ample accommodation for two persons and for a large quantity of luggage. The "Richardson" 12-14-h.p. two-cylinder car exhibited has already been described in the *Journal*, so we pass on to the *chassis* of Messrs. Richardson's latest production, a 24-h.p. car with pressed steel frame. The four-cylinders are cast in two pairs, the inlet and exhaust valves being all actuated mechanically off one cam shaft. The inlet valves are provided with a variable lift device actuated automatically by the governor. The water circulation is maintained by a chain-driven pump and a ribbed radiator of the latest type, neatly set in a frame which fills up the front opening in the bonnet. The power is transmitted through a specially-arranged self-contained clutch to a gear-box, giving four speeds forward and one reverse. The change-gear pinions are all bolted to flanges so that they can easily be renewed if necessary. From the gear box a cardan shaft conveys the power, through bevel gearing, to the rear live axle. Special attention has been paid to the brakes, one being fitted on the forward end of the bevel gear shaft near the cardan joint. On the shaft is mounted a special disc, in which is an expanding brake, actuated by a cam controlled by a lever. Altogether the Richardson cars appear to be of high-class construction, both as regards the *chassis* and the carriage work, large provision having been made in the way of lockers and pockets for the convenience of the passengers. At this stand was also to be seen the Wallis motor map, a mechanical arrangement in a case by which 400 square miles, ½ inch scale, of any part of England and Wales can be rolled into position with the greatest ease.

The "Arbee" is the name of a new two-seated car which MESSRS. RODGERS BROTHERS are bringing out to meet the demand for a popular-priced vehicle. The motive power is supplied by a 6-h.p. vertical engine set in the forepart of a tubular frame. The motor has a cylinder 4-inch bore by 5-inch stroke, and runs normally at from 800 to 1,000 revolutions per minute. The valves are all mechanically actuated, while the water-cooling is on the thermo-syphon system, with fan-cooled honeycomb radiator. Two speeds forward and a reverse are provided, the engine driving through a clutch and bevel gear on to the first shaft of the gear box, which is set across the frame. The various change-speed pinions are always in mesh, the requisite pair being brought into action by means of "dog" clutches at the side of the pinions. From the gear box a single centrally-located chain transmits the power to the gear live axle.

MESSRS. E. MENDELSSOHN AND CO., of Levallois-Perret, France, exhibited a number of petrol cars of their construction ranging from 6-h.p. to 15-h.p. These follow the usual lines of chainless cars, the largest type having a four-cylinder Mutel engine with mechanically-operated inlet valves and Xenia carburettor. A feature of this vehicle is the special provision made for the lubrication of the differential and bearings on the rear axle, a continuous circulation being ensured by utilising the hollow radius rods as oil pipes.

The Dechamps cars were once more to be seen at the stand of the DECHAMPS MOTOR COMPANY. The general arrangement closely follows what may be termed Panhard lines, the power being conveyed through a clutch, gear-box, and two side chains, three speeds and a reverse, all controlled by one lever, being available. The engine is fitted with automatic governor acting on the inlet. A special feature of the Dechamps cars is to be seen in the band brakes connected with the rear wheels, the band being put in and taken out of contact with the drum by a double-threaded screw actuated by a hand lever. A complete 18-h.p. car was shown, the body work of which was well worthy of inspection; it takes the form of a side entrance double phaeton. Side by side with this was a 10-h.p. double-cylinder car and a 22-h.p. four-cylinder vehicle. The engine has separate cylinders, water-cooled by means of friction-driven pump and honeycomb radiator. A feature of the latter is that the belt driving the fan connected with the cooler is at the front of the radiator.

Digitized by Google

ELECTRICAL CARS.

A newcomer in the electrical vehicle field is the ANTI-VIBRATOR, LIMITED, which had on view a well-finished landaulet (Fig. 58) and a victoria. No frame, in the usual sense of the term, is used, the body being supported on the axles in a special way; the axles themselves are tied together by tubular radius rods in such a manner that each may adjust itself to any inequalities in the road. Two 3-h.p. motors are provided; they are of the enclosed type, with the armatures running on ball bearings; each motor drives one of the rear wheels through spur gearing. The necessary

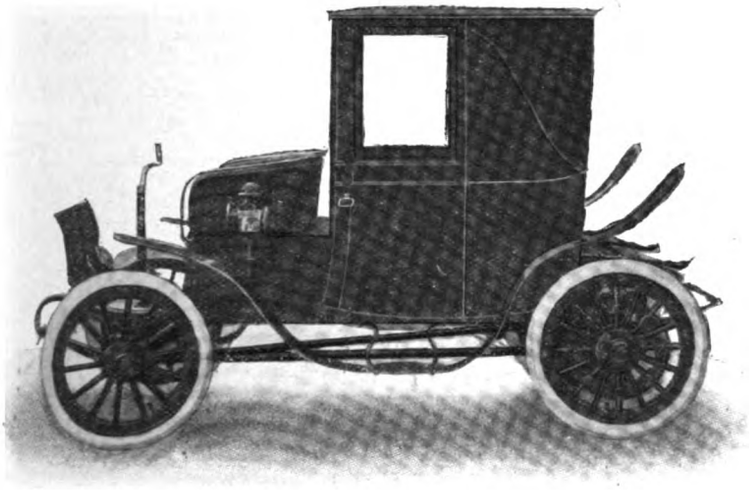

Fig. 58.—The Imperial Electric Landaulet.

energy is furnished by a battery of forty-four cells, arranged in two groups —one under driver's seat and one behind the rear seats. The capacity is equal to a run of about forty miles over good roads on one charge. The speed controller measures only 15 in. by 4 in., and is fitted under the driver's seat. It provides three speeds forward, one reverse, and one neutral or off position. By a special contrivance it is rendered impossible for the driver to start off with a rush or to change the speeds abruptly from first to third, a frequent source of damage to the motor and gear wheels. Four brakes are provided—two on the driving wheels and two on the motor shafts. Each is double-acting and will hold the carriage from running backwards or forwards. Near the driver's left hand is a safety device, by which, on withdrawing a plug, all electrical connections are cut off, so that the car may be left without danger.

A number of light electrical vehicles were shown by the LONDON ELECTRO-MOBILE SYNDICATE, LIMITED, these including a two-seated stanhope, a tonneau, and a light van to carry loads up to 4 cwt. The vehicles are propelled by an electric series-wound motor located at the rear, and driving on to the back axle through centrally-located enclosed spur gearing. The power is furnished by a battery of forty-two accumulators of the Hart type carried in the rear portion of the body, one charge being sufficient for a run of from thirty-five to forty miles on good roads. The controller is of the series-parallel type, adapted to give five forward speeds, two reverse motions, and two electric brakes. A pedal actuates a band brake on the rear axle. Steering is by means of a tiller or wheel. Solid or pneumatic tyres can be fitted to the road wheels, which are of the artillery type. The "Lems" cars, as they are termed, appear to be especially adapted for doctors' use, and have already been adopted by several members of the medical profession. The van (Fig. 65) is well adapted for use by tradesmen; it takes a charging current of about 10 amperes, and at the usual price of current for power purposes cost about 10d. for a run of thirty miles, for current at 100 volts. With batteries complete its weight is but 14 cwt., which is very moderate for a car which is strongly built and intended for every-day service.

The LANCASTER MOTOR GARAGE had on view a Mildè landaulet, one of the most successful types of electric carriages in France. A compound-wound Mildè motor of the differential type, carried at the centre of the hind axle, drives both rear wheels through internal diagonal spur gearing. The battery is carried partly under the driver's seat in front and partly beneath the passengers' seat behind, and is made up of 44 Heinz cells of 155 ampere-hour capacity at 80 volts. It furnishes sufficient energy to drive the car about 40 miles on a single charge. The steering is effected by a hand-wheel fixed to a vertical pillar to which the controller is also attached. The latter gives seven forward speeds, two electric brakes, and two speeds backwards.

The BURLINGTON CARRIAGE COMPANY, Limited, which has established a garage and charging station at 41, Grosvenor Mews, New Bond Street, W., had on view a Scheele electrical landaulet. The vehicle is provided with a battery of forty cells of a capacity sufficient to run it a distance of from 30 to 50 miles on one charge. Two electrical motors are fitted, these driving the rear wheels through spur gearing. The controller is adapted to give five forward speeds, two reverse, and two braking positions.

A new firm in the motor trade is MESSRS. BATH AND SON, of King's Lynn, who have opened a repair shop, garage, and charging station at 36, Lorne Gardens, Park Road, Regent's Park, N.W. Their exhibit included an electrical brougham and a landaulet, fitted with Lundell motor driving the rear axle through enclosed spur gearing. The battery consists of forty-four cells, having a capacity equal to a run of about forty miles on one charge. The controller is adapted to give five speeds forward, one reverse, and an electrical braking position. At this stand was also to be seen a 20-h.p. M.M.C. car fitted with a special Limousine body of Messrs. Bath's construction. This is a branch of work to which special attention is devoted by Messrs. Bath, that of the Limousine, as well as of the electrical vehicles, being of a high order.

MESSRS. MORGAN AND CO. exhibited an electrical victoria and a dog-cart. These cars are fitted with double-rotating "Still" motors driving the rear wheels through side chains. The motive power is supplied by a battery of forty Sola accumulators, the capacity of that in the victoria being sufficient for a run of 25 to 30 miles at speeds up to 15 miles per hour. The controller is adapted to give three forward speeds, one reverse, and a neutral "off" position.

STEAM VEHICLES.

Among the exhibitors of heavy steam wagons who made their first appearance at the London Show was the HERCULES MOTOR WAGON COMPANY, of Levenshulme, Manchester, whose five-ton vehicle is illustrated in Fig. 59. The boiler is of the vertical fire-tube type with straight solid-drawn steel tubes, suitable for either coke or coal fuel. The outside shell can be removed for cleaning; the boiler, which is constructed for a working pressure of 200 lb. per square inch, is dropped between the main frame, to which a patent carrier plate is firmly bolted, and is placed in rear of the front axle; the foot plate is below the main frame and the boiler is fired from the front. It is fitted with double safety valves and Klinger water gauge. The water is supplied through a water heater by means of a pump driven by an eccentric upon the compensating shaft; there are also two injectors as an auxiliary supply. The engine is of the compound link motion reversing pattern, fitted with piston valves; the cylinders are 4 in. and 7 in. diameter by 6 in. stroke. It can be converted at will, from the driver's seat, into a double high-pressure engine with separate exhausts, thereby giving increased power in cases of emergency. With this arrangement there is claimed to be no back pressure upon the high-pressure piston. The engine and gearing are contained in dust-proof casings and run in an oil bath. The wagon is fitted with two speeds, differential gear, and patent locking appliance. The change speed is effected by means of a special device, doing away with internal fork clutches. The power is transmitted by two strong roller chains from steel pinions upon the compensating shaft to chain wheels bolted to the special rear road wheels. The front axle is of special construction, it being built in accordance with Perkins' patent, the steering being on a modified Ackermann principle, operated by worm and wheel, giving a large angle of lock without reducing the stability of the wagon. The axle is so arranged that it can oscillate, allowing either of the front wheels to mount any obstacles up to 8 in. without causing any distortion of the frame. The main frame of the wagon, which is carried upon four laminated plate springs attached to the axle by means of strap bolts, is of channel steel, braced and constructed so as to carry the whole of the machinery, boiler, and tank. The back axle is of forged steel, and is held in position by means of two strong pivoted radius rods, thereby allowing for the deflection of springs. As already mentioned, the rear road wheels

Fig. 59.—The "Hercules" Steam Wagon.

are of special construction, the hub, spokes, rim, and sprocket flange being in one casting. Between the rim and steel tyre a wood felloe is introduced, which is claimed to give to the composite wheel the same resiliency as a wood wheel without any of the drawbacks of the latter. Altogether the "Hercules" is an interesting addition to the types of heavy steam vehicles on the market. We may add that Messrs. Shippey Brothers, Limited, have recently been appointed agents for these wagons in the London district.

Digitized by Google

MESSRS. BAILEY AND LAMBERT had on view a *chassis* of the Turner-Miesse 10-h.p. steam cars, built by TURNER'S MOTOR MANUFACTURING COMPANY, LIMITED, and which, ere the Exhibition closed, bore a card to the effect that it had been sold to a gentleman in Ceylon. The car (Fig. 60) is driven by a horizontal three-cylinder engine, steam for which is provided by a flash-type generator. The latter is made of solid-drawn weldless steel tubing of about 200 ft. in length, which is made up into sixteen layers of snake coils. The burner is of the Bunsen type, and consumes ordinary American paraffin oil as fuel. The oil is fed from tank to burner by air pressure, automatically maintained by a small pump mounted on the engine crank-shaft. The engine is of the single-acting trunk type, and has inlet and exhaust valves of the mushroom pattern, a construction which obviates the necessity of any glands or packing. The valves are operated by two cam rods, actuated by the steam lever on the steering post. Among the detail improvements in the 1904 model is a pilot light which keeps up the necessary temperature of the generator, enabling the car to be left standing for hours without attention, and yet be ready at a moment's notice to start. Steam is now cut off as desired by a throttle valve, operated by a pedal, which also applies the brake; while the water regulator has been improved to enable the driver to see at a glance how much water is passing to the generator. Sufficient water for a run of eighty miles can be carried; while the capacity of the fuel tank is equal to 100 miles' running. We may add that the car is built entirely at the Turner Company's works in Wolverhampton, and that the consumption of fuel is about one gallon per hour.

GENERAL EXHIBITS.

Among the miscellaneous exhibits of utilitarian interest to motorists was the display of the PAGE MANUFACTURING COMPANY. This consisted of a selection of their specialities in oils, polishes, enamels, paints, and similar necessary articles. Their "Aluma" paint is of aluminium hue, and admirably prepared to give an effective appearance to metals covered therewith. The "Lumo" silver enamel is another special line with the Page Company, who have also brought out the Radium burning and lubricating oils in conveniently shaped flasks. Calcium carbide, transparent enamels, and the well-known "Tab" polish were also to be seen on the stand of the Page Manufacturing Company.

Ignition accumulators of every description and capacity were shown by MESSRS. SANDERS, REHDERS AND CO., of the Pfluger Accumulator Works. The Pfluger batteries are supplied either for acid or with the makers' special paste. Some excellent batteries for motor-cycles and light cars up to 8-h.p. were on view. One good type is that known as No. 102. Two of these batteries will fit the tank of any ordinary motor-cycle, one being in use and the other kept in reserve. Then, should accident occur, the spare cell can be brought into requisition. For heavy motor-vehicles four-volt batteries are made, with an approximate running mileage of 2,500 miles. The Pfluger protected batteries were also exhibited, these being intended for heavy wear. They will stand the vibration of the motor on the worst roads without damage, and are said to be capable of sustaining a fall without injury, consisting, as they do, of celluloid cells fitted into wooden cases.

MESSRS. SMITH, PARFREY AND CO., LIMITED, who possess an electric welding plant at their works at Hammersmith, had a good show of motor-car wheels fitted with rims for any description of tyre. Wheels for heavy steam lorries, as well as for the lighter type of petrol car, were also on view. Not only on their own stand, but also among the car exhibits elsewhere in the show, were to be found specimens of Messrs. Smith, Parfrey and Co.'s productions. Bent timber is another speciality of the firm, this being supplied to any special patterns or drawings. Car backs, wings, rails, and other articles were shown in bent timber. Other exhibits of the firm included wrought-iron treads of varied design, and with ample foot space, stamped forgings for motor work, motor axle forgings, motor springs, steering axles, and a 12-h.p. bevel-driven axle.

Waterproof goods of every description were shown by the UNION WATERPROOFING COMPANY, who had a fine display of van and car covers in green, black, or white material, being made of flax canvas fitted with ropes, and of such a character as is likely to win favour with private owners of automobiles. Other exhibits included driving aprons, waterproof trousers, jackets, overcoats, leggings, etc. In indiarubber waterproof coats, some good and useful patterns were on the stand, both in single and double texture. Miscellaneous exhibits of the Union Waterproofing Company comprised the Crown chain lubricant, a white rubber renovator, and a dressing for leather clothing which renders it waterproof, soft, and pliable.

Among coach builders, MESSRS. BROWN AND HUGHES had a distinctive show of motor-car bodies, including a landaulet to seat four persons inside. The front is a removable one, and the whole design is noteworthy in view of the comparatively short *chassis* for which it was intended. The firm have lately laid down electrical power to drive their wood-working machinery, and their facilities are ample for the making of motor-car bodies, whether in wood and iron or in aluminium.

MESSRS. SALSBURY AND SON, LIMITED, showed a large and varied assortment of Salsbury-Flare and Salsbury-Dietz lamps. The former are too well known to need any comment, with the exception that they have been improved in many ways for the coming season, a new reflector being now fitted. The Salsbury-Ovalite and Salsbury-Searchlight were also shown. These are rapidly coming into favour with the motoring public on account of their great lighting powers. The Salsbury-Dietz Orient lamp is in four finishes, and the Salsbury-Dietz Masterpiece in two finishes. The firm are well to the fore with the new regulation tail lamps and devices for carrying the number-plate on motor-cycle head lamps. Spark plugs, accumulators, wire, coils, and every accessory motorists require were to be found on this stand, one of the most useful of these being the Salsbury-Barratt motor jack, which, although only introduced a year ago, has rapidly come to the front. The "Strictor" belting was also exhibited by Messrs. Salsbury and Son, Limited; and among new lines for 1904 were the "Dazlit" metal polish and "Gre-Solvent" automobile baskets, "Tydee" waste-trays and "Tydee" oiler-trays.

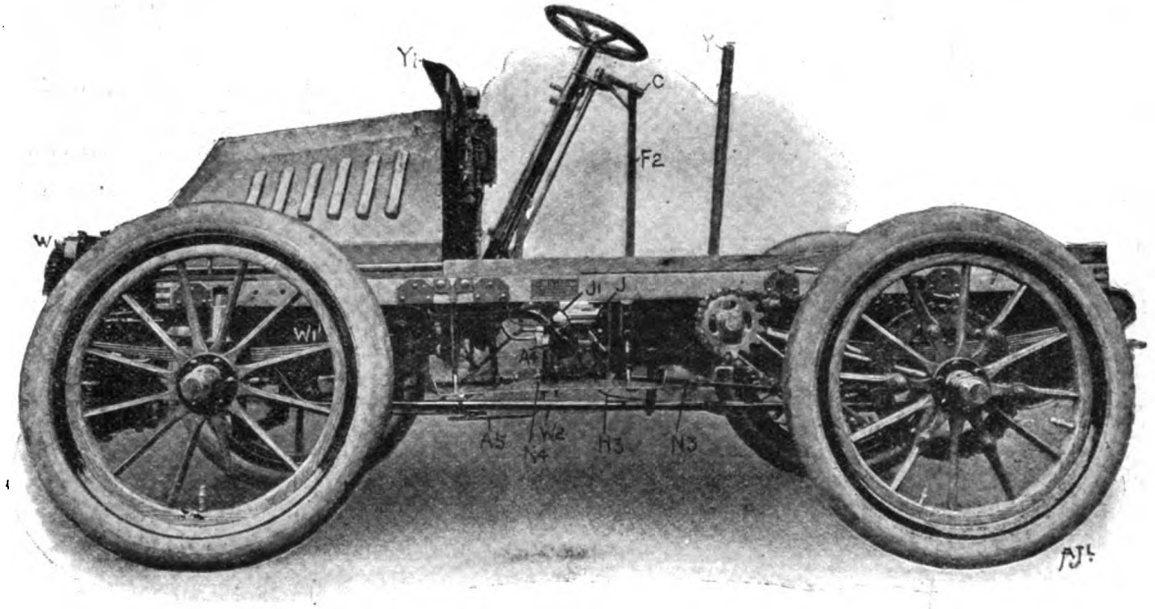

Fig. 60.—Chassis of 10-h.p. Turner-Miesse Steam Car.

The WILLIAMS TYRE COMPANY showed their solid rubber tyres for motor-cars, these being secured to the wheels by means of patent bands and fastenings, as described in our issue of February 20th last. The firm hold which the hook and steel screw—a special feature of the construction—secure on the band prevents the possibility of this working loose, and so does away with the chance of creeping.

Among tyres that of the PETER UNION TYRE COMPANY was one in which the public took a lively interest by reason of the fact that it has been supplied to the Prince of Wales, and has also been used on the G.W.R. motor-'buses. The company has brought out a rubber protector which permits the use of covers long after they would otherwise be discarded. They form a resistance to the bursting tendency of inner tubes in the event of a large cut in the cover. The protector is in the form of a circular rubber tapering towards each end and thickened in the centre. This is laid loosely inside the cover, the tube lying closely inside it. Injury to the tube is thus prevented, the idea being one deserving the careful consideration of motorists.

Digitized by Google

A Coventry firm which is devoting considerable attention to the construction of petrol motors is the FORMAN MOTOR COMPANY, LIMITED, who had an interesting display in the gallery of engines ranging from 3½ to 20-h.p. The motor-cycle engine is of the air-cooled type, made with either automatic or mechanically-actuated inlet valve. The motor has ample bearing surfaces throughout; the flywheels are fitted inside the crank case in the usual manner, and the whole of the gear is enclosed in oil-tight cases. The cylinder dimensions are 80 mm. bore by 80 mm. stroke, the full power being developed at a speed of 1,500 revolutions per minute. The Forman 4½-h.p. water-cooled motor for use on two-seated motor-cycles, light cars, and motor-boats has already been described in the *Journal*. It has a cylinder 90 mm. by 90 mm., the inlet valve being mechanically actuated. The 10-h.p. and 20-h.p. engines are of the same pattern, one having two and the other four cylinders cast in two pairs. The cylinders are 105 mm. bore by 110 mm. stroke. The engines are fitted with the ordinary atmospheric valves, and are governed on the throttle. The base chamber is in aluminium and the two halves provided with substantial arms for supporting purposes. Another type of engine—one of the Forman Company's latest productions—is shown in Fig. 61. This is a 14-16-h.p. motor, designed with a view to supplying the demand for a miniature four-cylinder perfectly balanced elastic engine. It consists of four separate cylinders, 80 mm. bore by 90 mm. stroke, mounted upon a base chamber, with carrying brackets of such a nature that no difficulty need be experienced in fitting it to any type of frame, either by attachment to the false *chassis* or the main frame. The engine is fitted with a solid four-throw crank with ample bearing surfaces. The whole of the cam gearing is enclosed in oil-tight cases. The cam shaft and two to one gear, together with the governor, are enclosed in oil-tight cases, which

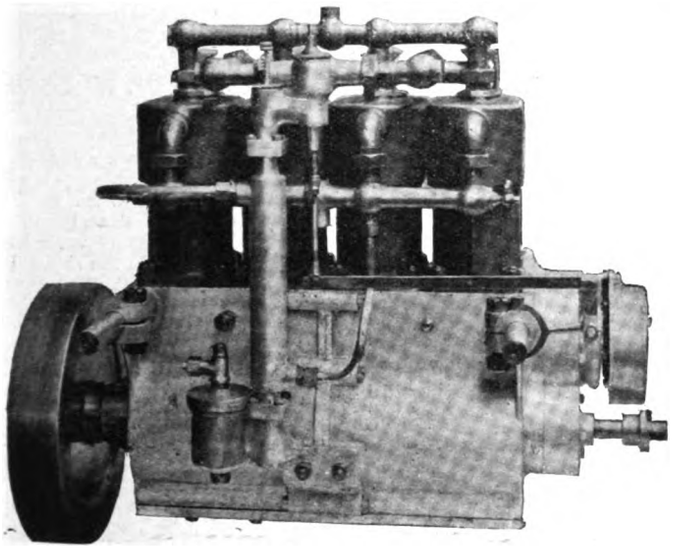

Fig. 61.—The "Forman" 14-16-b.h.p. Motor with Automatic Carburettor.

are readily opened out for inspection. The cam shaft is so arranged that it can be removed complete with a minimum amount of work. The engine is fitted with a centrifugal governor acting on the inlet; it can be set to run at any desired speed, while the engine is so elastic that it is capable of running at from 200 revolutions to 2,500 revolutions per minute. This is obtained by a special automatic carburettor which provides for a mixture according to the speed of the motor, and which is referred to below. The total weight of the engine, inclusive of flywheel, is 230 lbs. We understand that the Forman Company have met with quite a large demand for this engine on account of its suitability for converting one and two-cylinder cars to the more modern four-cylinder type. Fig. 62 gives a sectional view of the Forman automatic carburettor, to which reference has already been made, and which is seen fitted to the engine illustrated above. A is the petrol supply to the float chamber through the cut-off needle B, which can be regulated by a screw and lock nut. C is the float cutting off the petrol supply and maintaining it at a constant level in the jet nipple E. D is the float chamber, which is made very deep and below the level required for the feeding of the jet, the object being to allow sediment which may collect to fall in the sump-pit shown at the bottom of the float chamber. An ordinary pet cock is provided for draining purposes. The carburettor takes in air through the perforated in-take F, to the regulating flap G, which assures direct starting of the motor when cold. The air, in passing through the vaporising chamber, sucks a certain proportion of petrol from the jet nipple E, passing up through the vaporising pipe H, which, it will be noticed, is jacketed throughout. This ensures the carburettor working under constant conditions and prevents freezing. Either hot water or exhaust gases may be circulated through the jacket. The valve K supplies additional air to the mixture when the engine is running exceptionally fast. It is provided with a screw for adjusting the lift, and, in addition the maximum intake can be controlled by the regulator L. M is an ordinary cut-off valve controlled by the governor, which is of the centrifugal type, and fitted on the cam shaft of the engine. The mixture, after passing through the valve M, is distributed in the feed pipe to the various cylinders. T is a snifting valve; when the valve M cuts off the mixture entirely the vacuum is reduced, and a certain proportion of fresh air is permitted to flow into the cylinders through the valve T, thus cooling the cylinder walls. At this stand was also to be seen an example of the radiators made by the COVENTRY PLATING AND PRESSWORK COMPANY, LIMITED, the aluminium tubes being claimed to be 40 per cent.

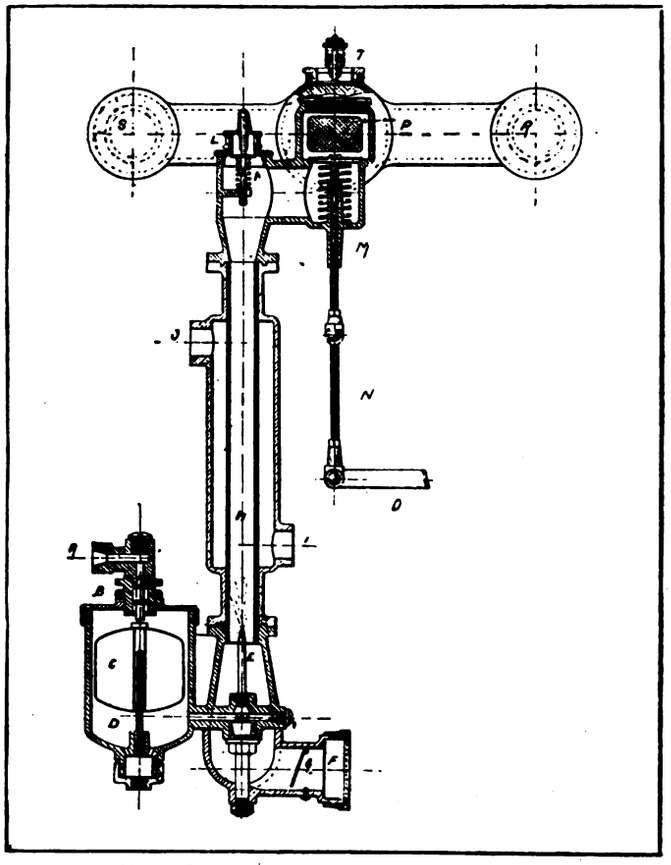

Fig. 62.—Section of "Forman" Automatic Carburettor.

lighter than the usual type. The increased efficiency is obtained by the use of aluminium radiating fins. These are in actual metallic contact with the tube by a patented method of fixing, no solder being used.

The ASCOT MOTOR COMPANY introduced a new motor-bicycle with a 2¾-h.p. engine set vertically in the frame just forward of the bottom brackets. The cylinder diameter is 80 mm. bore by 80 mm. stroke. Both valves are mechanically actuated, this being performed in a simple and ingenious way, only one cam being used for the two valves. A diagram of the

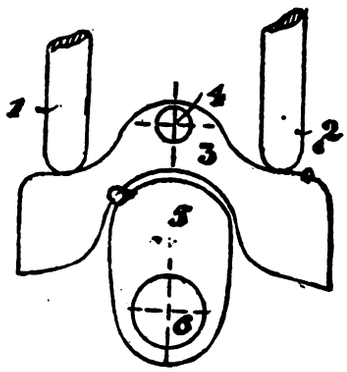

Fig. 63.—The "Ascot" Valve Gear.

device is given in Fig. 63. It will be seen that between the two valve lift rods is pivotted a rocker 3. As the cam 5 is rotated it lifts each valve rod in turn, and at the desired interval. In this way no additional cam or gear wheels are required to actuate the mechanical inlet valve, which has a quick closing action, owing to the special shape of the rocker. The machine is of the belt-driven type, the levers controlling the carburettor and throttle valve being ingeniously arranged. A two-seated motor-cycle with 3½-h.p. engine on similar lines was also displayed.

The stand of MR. W. H. NEWMAN, A.M.I.M.E., proved a very interesting one to engineering visitors to the show, the exhibit comprising a new adjustable universal joint or coupling and a change-speed indicator. In almost every motor-car universal joints or couplings are used, many live axle cars having as many as three. These joints are made in a variety of forms, but in few of them is any provision made to take up wear, with the result that when they become slack they can only be tightened

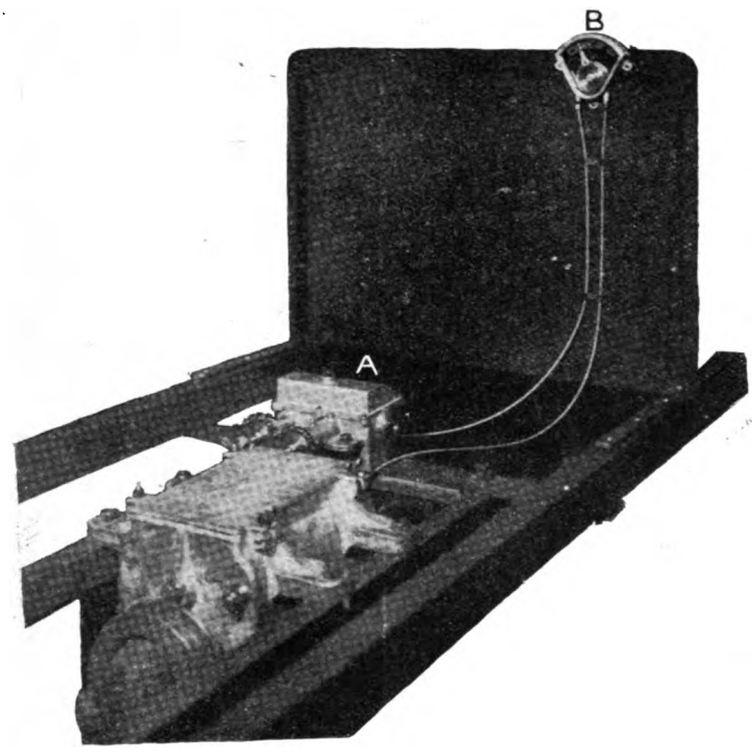

Fig. 64.—The Newman Change Speed Indicator.

up by renewing the parts. The Newman adjustable universal joint consists of a simple arrangement by which the working parts of the joint are made adjustable, so that the effects of wear can be neutralised and the joint always kept adjusted to a nicety. The ends of the shafts are forked, four segmental blocks being fitted to the sides of the forks. These segmental blocks have a conical screw thread cut on their outer surface, on which a ring is screwed which binds the whole joint together. It will be seen that if the ring is screwed up the cone all the blocks are forced in evenly towards the centre and the joint is tightened up. If it is screwed the other way the joint is slackened. Simple means are provided for locking the ring after it has been adjusted. The Newman change-speed indicator (Fig. 64) is another exceedingly interesting device. The difficulty of changing speed with the ordinary change gear, in which the wheels are arranged to slide in and out of mesh, is well known. By dint of practice a driver can, of course, become very proficient, but even the most skilled motorist may occasionally make a mistake when changing speed, and a novice may damage the gear teeth very seriously by attempting to force them into mesh. This difficulty is, of course, due to the fact that it is not possible to tell when the wheels are running at the correct relative speeds which would enable the teeth to engage without shock or jar. The Newman change speed indicator is claimed to entirely remove this difficulty; it indicates at all times the exact relative speeds of the shafts in the gear box, and thus enables the driver to slide the wheels into mesh at the right moment without shock or jar. The apparatus consists of a small aluminium box A, containing simple gearing driven by chains from the shafts in the gear box. The box A is connected by two Bowden flexible wires to an indicator B fixed on the dashboard in sight of the driver. The indicator has a pointer and two to four figures, according to the number of speeds fitted on the car. When the car is running on any given speed, *e.g.*, the second, the pointer will remain stationary at the figure 2. If now it is desired to change on to the third speed, the speed lever is moved so as to put the second speed gear wheels out of mesh. The pointer will then commence to move towards the figure 3, and at the moment when it reaches that figure the speed lever is moved into the third notch, the wheels going into mesh without any trouble. If the speed were being changed down to the first, the pointer would commence to move towards the figure 1 as soon as the speed lever was moved out of the second position, and as soon as the pointer reached the figure 1 the first speed could be put in without the least difficulty. It will be seen from the above that by the use of the Newman indicator changing speed is made easy, as it is only necessary to watch the dial and move the speed lever when the pointer reaches the figure.

A seamless yoke coat of good design was a leading exhibit of MESSRS. HAXTON BROTHERS, who have entered into the business of automobilists' tailors with some excellent garments. This particular pattern has a capital appearance, and should prove a warm comfortable article of raiment. It is most effective as a protection against windy and wet weather, and should give the makers a good introduction to the motoring world.

Motor lubricants were a feature of the exhibit made by PRICE'S PATENT CANDLE COMPANY, LIMITED, who have every facility for the production of high-grade goods of this class. Their "Motorine" is prepared for air-cooled and water-cooled cylinders, "Rangraphine" for motor chains; "Belmoline" for axles and bearings; and their gas engine oils are suitable also for water-cooled cylinders. Many are the specialities of the company for motorists, and space forbids anything more than the briefest enumeration. For change-speed gear boxes of the Daimler or Panhard type, there are two grades of "Price's Battersea Gear Oil" for winter or summer use respectively. An effective medium for the protection of the plated parts of cars from the corrosive action of a damp atmosphere was also shown. Special attention has been given to the subject of lubrication, and Mr. J. Veitch Wilson's pamphlet issued by the company should be read by all interested in automobiles.

Among the ignition batteries at the Exhibition that of the A.B.P. ACCUMULATOR COMPANY, LIMITED, attracted some notice. These are well known to owners of cars. They are supplied incelluloidcases, and the company's list giving particulars of the various sizes in which they are made will be found a useful pamphlet for reference.

The Prested battery was shown by the PRESTED MINERS' LAMP COMPANY, LIMITED, whose improved accumulators are fitted with a new device to prevent the creeping of acids and leads. The Prested cells are well constructed, and special tests recently made have demonstrated their constancy and reliability. Celluloid cases are used, the grids and electrolyte being of the familiar kind. A special kind of paste is used, and altogether this form of battery is one that motorists would do well to consider.

Motor fittings and accessories were shown by MESSRS. THOMAS NOAKES AND SONS, whose first appearance at these exhibitions proved a singularly successful one. This firm is making a speciality of accessories and fittings for both heavy steam vehicles and petrol cars of lighter build, and their exhibits included expansion and swivel joints, petrol taps, valves of all kinds, gauges, lubricators, pumps, etc. One type of patent automatic oil pump in which we were interested was that fitted with a ball friction drive. This is guaranteed to work on the highest speed engine, and to feed any gravity or thickness of oil. It only lubricates when the engine is working, and the supply of available oil can be seen at a glance. The James and Browne oil distributor is another special line with Messrs. Noakes and Sons. The construction of this type enables the sight glasses to be easily removed and replaced from the top without disturbing the connections of the distribution pipes. The distributing box is fixed independently of the oil reservoir, with which it is connected by a suitably-arranged pipe.

MESSRS. SUTHERLAND AND MARCUSON exhibited their "Umpire" batteries and accessories for ignition purposes on motor-cars, motor-cycles, etc., and also their batteries for car lighting. The novelty which they

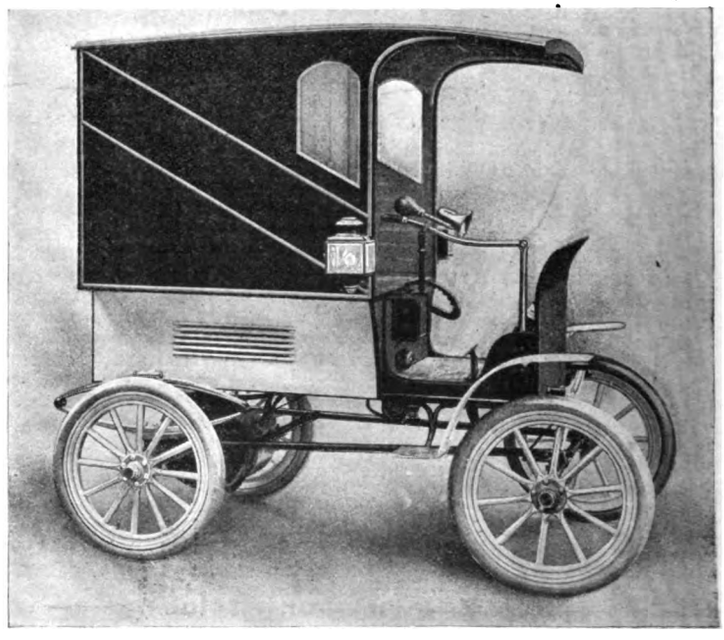

Fig. 65.—The "Lems" Electrical Delivery Van. (*See page* 107.)

showed was a new accessible skeleton type battery, which, while it can be made thoroughly liquid-tight, can at the same time be opened up and reclosed in a few minutes. The elements are provided with non-corroding terminals and are of the usual "Umpire" type, in which ribbed porous separators entirely occupy the space between the plates. The latter are held together by means of acid-resisting elastic bands, keeping the active

Digitized by Google

material constantly under pressure and preventing it from falling away or losing contact with the grid. These are placed in a box of a special vulcanite material, and then clamped in a skeleton wood box with a strap, which facilitates transport. They are unbreakable, and when batteries have frequently to be carried, seem to provide just what is wanted.

A new radiator was shown by the LUNE VALLEY MOTOR CARRIAGE COMPANY, the feature being that the usual radiating fins are replaced by a triangular helically-formed coil of phosphor bronze wire. The result is not only a cooler of high radiating power, but one of great strength combined with lightness. The radiator is made in a variety of styles, and bids fair to meet with a large adoption by motor-car builders.

A reversing gear for motor-launches, etc., was shown in sizes for motors of from 2 to 20-h.p. by MR. K. BARKHAM. This is designed to secure a free engine ahead and astern, wth only one lever, and the simplicity of construction is a considerable point in favour of the device. The main working parts are of a special alloy of phosphor bronze, and all are covered in. The gear can be bolted direct on to the flywheel, fitted on to the crank shaft of the engine, or worked on a separate bedplate.

Aluminium castings of all descriptions were the first exhibit to catch the eyes of visitors as they entered the Hall, these being evidence of the enterprise of Mr. R. W. COAN, who has entered into the business with a keen regard to the requirements of motor-car makers. Hence the varied character of his display.

In addition to a Baby Peugeot car, the BADMINTON MANUFACTURING COMPANY displayed a new non-skidding and non-puncturable band for the pneumatic tyres of motor-cars and cycles, which they have named the "Badminton." The band is made of a special quality of chrome leather, the tread having steel studs fixed in it, and it is attached to the outer cover of the tyre in such a way that the band and tyre are claimed to become a solid surface, which cannot be separated. The resiliency of the tyre is said to be in no way affected, nor has it any retarding effect on the speed.

The well-known LONGUEMARE carburettors were displayed by Madame Lockert. These are made in sizes suitable not only for motor-cycles, but for the largest cars. The patterns exhibited included those recently introduced with auxiliary air inlet. Messrs. Longuemare have just issued a new catalogue, which contains a large amount of valuable information to users of this carburettor.

MESSRS. JOS. BAKER AND SONS, LIMITED, confined their exhibit to one of their motor change-speed gears, shown in operation. The gear, which is exceedingly compact, is of the epicyclic type, and gives three forward speeds and a reverse, all controlled by one lever. As we hope to describe the gear in detail in a later issue, we defer further reference to it at this time. We may, however, mention that Messrs. Baker have fitted it to a 8-h.p. De Dion car, and that over 5,000 miles have been run without trouble of any kind.

An interesting display of petrol motors was made by MESSRS. JOHNSON, HURLEY, AND MARTIN, who are devoting considerable attention to this growing branch of engineering work. The motors on view ranged from 3½-b.h.p. up to 16-b.h.p. The 3½-h.p. and 5-h.p. types have suction inlet valves, but the larger sizes are provided with mechanically-actuated valves. The 8-h.p. and 16-h.p. engines are of the same pattern, one having two cylinders and the other four cylinders, 90 mm. bore by 100 mm. stroke, the normal speed being 1,000 revolutions per minute. The four cylinders are cast in two pairs, and are provided with ample water-jackets. The crankshaft is made in one piece, and is provided with a large diameter boss, to which the fly-wheel is bolted. The crank chamber is of aluminium, and is provided with suitable brackets for attachment to the frame. The inlet valves are placed over the exhaust valves, and are interchangeable therewith. They are actuated by means of lifting rods and tappets operated from a second camshaft, which also actuates the exhaust valves. Special provision has been made for the lubrication of the cylinders and the various bearings, while the base chamber is provided with inspection holes both at the back and at the bottom. At this stand was also to be seen an "Alpha"—the name by which this firm's engines are known—12-h.p. double-cylinder engine, the dimensions being 4⅝ in. bore by 4¾ in. stroke. This is a relatively slow engine, running normally at 800 revolutions per minute, and having the inlet valves actuated by rods and tappets.

The improved seat for motor-cycles described in our issue of the 19th ult. was shown by MR. R. COOKE.

The "Omne Tempus" motor coats formed an attractive exhibit of MESSRS. SAMUEL BROS., LIMITED, who are entering the ranks of motorists' tailors with considerable spirit and enterprise. Fur-lined overcoats were another special line in which some good designs were on view, the exhibit being completed by an extensive selection of caps, gloves, and the score and one similar goods comprehended within the scope of the tailor who looks after the clothing wants of motorists.

An ingenious motor-cycle brake, already made familiar to readers of the *Journal*, was shown by MESSRS. WASS AND COCKS, LIMITED, of Ealing. This is the "Gripwell." It consists of a lever working in a clip attached to the compression stay of the machine. One end of the lever is fitted with a shoe having a dove-tail groove. The brake block is fitted into the latter, and can be supplied in V section or flat, according to the section of the belt pulley. At the other end of the lever is a pawl upon which the crank presses, when back-pedalling, and in this way the brake is applied. When not required the pawl can be instantly thrown out of action. Simple and effective, the brake has the further advantages of being reliable and inexpensive.

A good show of lamps was made by MESSRS. H. MILLER AND CO., LIMITED, whose acetylene head lamp is a good example of the improvement made in lamp construction during recent years. New tail lamps to meet the regulations now enforced were on view, as well as motor-cycle lamps with number plates. Motor oils were also to be met with on Messrs. Miller and Co.'s stand.

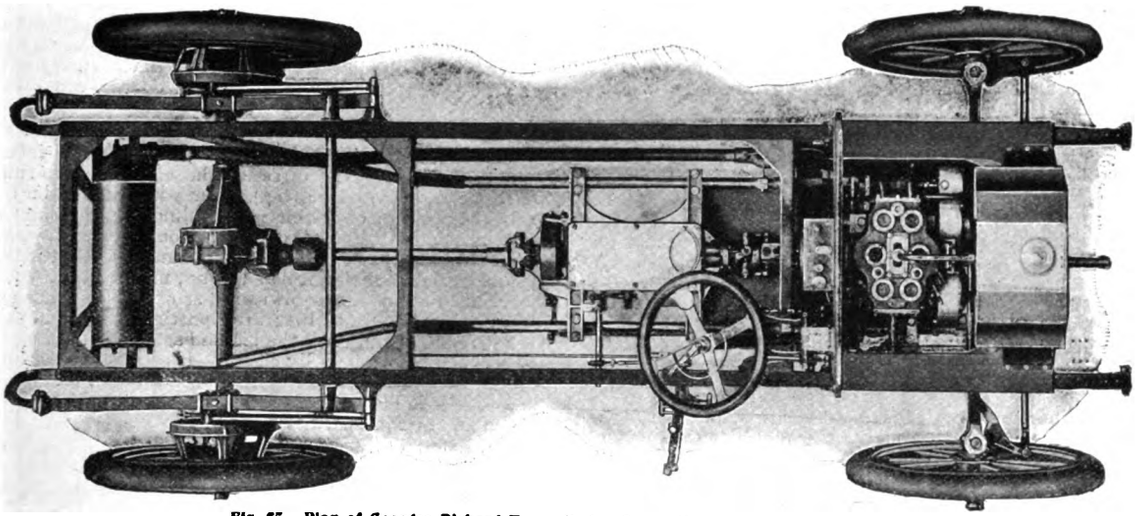

Fig. 65.—Plan of Georges Richard Two-cylinder Car. (*See page 77 last issue.*)

Motor clothing for ladies and gentlemen was shown by MR. C. R. BASE, whose removal to the West End has lately taken place. So recently have we referred to this gentleman's productions that detailed reference would appear superfluous on the present occasion; but mention must be made of the good selection of accessories now stocked by him.

Their oil cans and improved "Economiser" for storing paraffin and other oils were shown by MESSRS. JOSEPH KAYE AND SONS, LIMITED. A varied selection of engineers' small tools and gauges was shown by MESSRS. LUDW LOEWE AND CO., LIMITED, whose internal limit gauges are attaining considerable distinction. A display of D.W.M. ball bearings was a notable exhibit of this firm. The THOMAS SMITH'S STAMPING WORKS, LIMITED, made a fine show of drop forgings of every kind for the motor-car industry. Strength and accuracy are apparently combined with good workmanship in these manufactures. MR. A. G. TAYLOR had his "Quick Grip" spanner in the Berner's Hall. Motor chains were displayed by the COVENTRY CHAIN COMPANY, LIMITED, whose belt hooks and chain belts also found a place on this stand.

A collection of goggles, field-glasses, etc., was shown by MESSRS. AITCHISON AND CO., special attention being directed to one pattern, consisting of collapsible silk eye-cups, extended by a spring and fitting closely to the face, preventing dust or wind passing to the eyes.

Several ingenious improvements in the details of design of motor garments were to be found on the stand of MESSRS. J. W. LOVEGROVE AND CO., whose costumes for lady and gentlemen motorists have frequently been mentioned in these columns. Caps, veils, cloaks, rugs, muffs, etc., find a place in a representative collection, which also includes horns, lamps, bells and other accessories in great variety.

To be continued.

CORRESPONDENCE.

WHY CHAUFFEUR?

To the Editor of *The Motor-Car Journal*.

Sir,—Can you, or any contributor of the *Journal*, tell me why our English motor-car drivers should be called "chauffeurs?" I myself am one and cannot, and possibly other readers also cannot understand why a French word should be used in this or in any other case.

Surely some reader who is interested (like myself) in the British motor trades could suggest an English word, and therefore shun the word "chauffeur" from our gaze. I say, and most probably others will agree, when in England, be English. I feel quite certain that if you publish this query amongst the large circulation of motor-men, it would be quite an interesting subject, and we should soon get rid of that horrid term.—Yours truly,

E. S. Carter.

COST OF REPAIRS.

To the Editor of *The Motor-Car Journal*.

Sir,—The following may be of service to owners of 7½-h.p. Wolseleys, or, for that matter, any other type of car of like cylinder construction.

November 17.—Slight loss of compression in one cylinder, and new rings fitted by mechanic from well-known London firm. Cost £2.

February 12.—This cylinder still poor, and car sent to garage of same firm, with instructions to draw liner. Happening to call the following day I was told that both cylinders had been dismantled "while they were about it," although compression of other cylinder was exceptionally good. The liner of faulty cylinder was found, and also seen by me, to be very slightly oval. This one was therefore scraped and new rings fitted. The second cylinder, although perfect, had also new rings fitted "while they were about it." Beyond remaking usual "jacket" joints nothing was done to the car, and I was told to fetch her. Here is the bill:—

	£	s.	d.
Mechanic's time taking down engine and drawing liners and re-grinding and re-packing same, and making water-tight (liners found to be slightly oval), these were scraped and new piston rings fitted, and engine re-assembled ...	8	4	0
2 lbs. waste	0	0	6
6 piston rings	0	15	0
2 rubber rings	0	1	0
3 dozen split pins	0	0	9
1 exhaust joint	0	1	3
1 bolt and nut	0	0	3
	£9	2	9

When first shown liner to be oval, I suggested a new one, but was told it was not needed. A new liner would, per the Wolseley Company's charge, cost 25s. only, but a little "scraping" on the part of this firm pays so very much better. Advice. Where possible, always make a point of returning car to makers for repairs.—Yours truly,

Horseless Age (d).

To the Editor of *The Motor-Car Journal*.

Sir,—As a practical artisan mechanic I should like to express a few words in this matter. I greatly sympathize with "Chirurgeon" and others who are similarly placed. Having gained experience at mechanical and cycle engineering, some five or six years ago I turned myself to cycle and motor repairing. I have worked in several shops in different parts of the country. Perhaps it would surprise you to know the class of men who run many so-called repair shops. They are mostly motor and cycle agents, and carry on their trade by calling themselves motor manufacturers, cycle engineers, mechanical consulting engineers or experts, their past careers being, I found out, clerks, publicans, watch makers, barbers, racing men, etc. Of six firms I have worked for only two have been practical engineers. These adventurers do at times get good men who do not stop long. The general routine in these shops is that the mechanic has not a free hand. On many occasions an employer will muddle a repair for three or four hours, and when he has done enough damage he will put you to it, then you observe the nuts are rounded, the threads are stripped, or a few hammer trade marks and other things which you cannot counteract, and after spending some amount of time you are told that you have taken too much time on it, and we shall not get our money back. These experts often lounge about the workshop seeking for information, asking this sort of question? how do you do screw cutting? will you throw this in the lathe, and I will have a go at it, and what tool shall I use? On one occasion the employer said, it it was a cylinder of a watch I could manage it, I used to be a watchmaker once. These so-styled manufacturers are as deficient of machinery as they are of brains. I was once discussing this matter and was told that young men and others could, with a few tools and books, accomplish more in two years than an apprentice-engineer could in five years' apprenticeship, but I was not told at whose expense.—Yours truly,

P. M.

La[illegible] . Levegh—Sketched by Himself. [*Le Chauffeur*.

MOTOR RACING ON ENGLISH SHORES.

To the Editor of *The Motor-Car Journal*.

Sir,—With reference to "Yorkshireman's" suggestion that the hard sandy beach of Filey Bay might be found suitable for motor racing, a motoring friend informs me that Filey is a most inaccessible place for motor-cars. Perhaps "Yorkshireman," who states that he has cycled there, would be able to throw some light on the point.—Yours truly,

Lancastrian.

ADJUSTING VALVE GEARS.

To the Editor of *The Motor-Car Journal*.

Sir,—In reassembling a motor which has been taken apart how should one proceed to adjust the valve cam gearing so that the exhaust valve will be lifted at the correct point in the stroke of the piston? Any information you or any readers of the *Journal* can give me on the point will be esteemed by—Yours truly,

Puzzled Novice.

[Replying to "Puzzled Novice," in the first instance it is necessary to determine the direction the engine has to run (as this depends entirely on the valve setting), after which it will be necessary to ascertain the position of piston in the cylinder. This can usually be done by putting a small rod through the compression tap, or still better by removing the same. Now to set exhaust valve: turn the engine slowly round in the direction it has to run, until the piston is about an inch from the bottom of the downward stroke, the exhaust valve should then be set to commence to lift; after putting the cam in this position slowly turn engine round until the piston has completed its upward stroke, the valve should then be fully closed. If this is not so, but it still remains open, the cam should be shifted back a tooth and again tried. If this is carefully followed, "Puzzled Novice" will have no difficulty in getting his engine to run satisfactorily.]

STEAM V. PETROL.

To the Editor of *The Motor-Car Journal*.

Sir,—In a recent issue "Vapeur" writes saying that he has fitted an automatic air arrangement to cool the seating of his steamer (name not given); if he will kindly state particulars of same, it will be a boon to many steam motorists, also make of paraffin burner, and if suitable for "Locomobile." I may add that my water tank gets very hot without any return water system mentioned by "Steamer." I don't know if this is unavoidable.—Yours truly,

Another Steamer.

To the Editor of *The Motor-Car Journal*.

Sir,—I have read with pleasure a letter in the *Journal* from "Vapeur." I quite agree, a steam car, properly fitted, burning paraffin oil, is preferable to any petrol car selling at the price. I myself have a Stanley, burning paraffin, and the way the car behaves on the road is a treat. I have made many a petrol car costing at least twice the amount look small on a hill. Unfortunately there is at the moment a distinct prejudice against the steam car, yet I don't know that one can be surprised when one sees to-day the rubbish that has been dumped on the market in the past. But with such cars as the White and Stanley (true I have had no experience with the former, but I hear it well spoken of) before the public I fully expect the steam car to gain favour again.—Yours truly,

Paraffin.

RESPONSIBILITY IN REGARD TO DRIVERS.

To the Editor of *The Motor-Car Journal*.

Sir,—I have just read the report in the last issue of the *Journal* of the action brought by a doctor against Friswell, Limited, for loss alleged to have been suffered owing to the negligent driving of one of the latter's servants. The magistrates' decision as to the responsibility of firms supplying drivers, notwithstanding the notification on the firm's notepaper that no responsibility was undertaken, seems to me a most important one to traders throughout the country, and I venture to

Digitized by Google

suggest that this is a question which might with advantage be taken up by the Automobile Mutual Protection Association and the Society of Motor Manufacturers.—Yours truly,

AN OXONIAN TRADER.

DRIVERS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have been interested in the correspondence *re* drivers, and would like to give my view as an ex-coachman. I notice the majority of correspondents are motor mechanics. They seem very eager to enter private service. Is it because they are not efficient for the workshop? I know one or two mechanics, but I do not think their cars are always ready for the road any more than those of the ex-servants, and I am sure they do not turn out so smartly. "A Won" speaks against the valet and coachman chauffeur. As a rule ex-coachmen and valet drivers know how to keep their places as servants, and treat their masters with respect. They do not expect to be looked upon as friends and become confidential. I may say I have a good place and nothing to do but look after my car and drive; I have a good master, who pays me for my work, and trusts me; therefore I study his interests. I do all my own repairs unless it is a job for the lathe. I make it a rule never to leave my car at night until it is ready for the road next morning. I have often been working on it till 12 p.m. getting ready for next day. Would many mechanics do it? they would want to know if they were, going to get overtime pay. A well-trained servant turns out smart, clean shaved, with upright clean collar; the so-called driver mechanic is noticeable by his heavy moustache and low turned-down collar. I think a good servant with common sense, who takes an interest in his car, would be preferable to the mechanic.—Yours truly,

ONE WITH THE TIMES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—*Re* the correspondence concerning drivers, I should like to say a few words about them. As far as I can see, there are two classes of drivers The first, a driver-mechanic in the true sense of the word, one who from a mechanical experience gained from a trade such as turners, fitters, and smiths, fully qualifies himself to look after and repair a car as soon as it gets out of order, and who thoroughly understands when, and how, to get the best out of his car, without putting undue strain on the machinery—in fact, one who would look after it as if it were a child. The second driver is one, according to my idea, who learns the way to handle a car in a few weeks, at some driving school, and whereas before he learnt to drive he may have been anything but a fitter, etc., after, he is a fully-fledged mechanic and driver, who applies and gets a berth on a car, perhaps a new car, where there is nothing much to do for a few months, but after that if there are big ends to be taken up, or brasses to tighten, it has to go to the repairers, when a proper man would do the job in half the time and without the expense. I have been in a public garage, as mechanic, and during that time I have seen drivers who, I admit, knew the way to drive, but, beyond that, knew hardly anything about their ignition troubles, loss of compression, etc. And this class of mechanic are delighted if they can get a berth on a private car at 30s. per week, because they never had much more than £1 or 22s. until they became motor drivers. Like others of your correspondents, I have answered advertisements, but never received any successful replies. I am inclined to believe that the sort of men required were those who would cut the lawn, and do a bit of gardening, etc. In fact, a motor-coachman-gardener sort of chap. Now, Sir, if a gentleman gets a proper driver-mechanic, even if he is a bit more independent than the coachman, he will find he will be far more intelligent in motor matters, and will conduct himself quite satisfactorily, and always have the car ready when required. I must apologise for taking up such valuable space in your paper, and thanking you in anticipation for your insertion of this letter—I am, yours truly,

PUBLIC SERVICE DRIVER.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Having read with very considerable interest the correspondence which has appeared in your paper with regard to this subject, I have been much struck with the varied views of both owners and drivers on the main questions at issue.

Having recently had occasion to advertise in your paper for a driver, I refrained from naming any salary, and the replies, considerably over 150 in number, proved most clearly that the exorbitant and fanciful terms demanded a year or so ago do not find acceptance to-day. The wages asked in the replies referred to varied from 15s. per week minimum to £2 10s. maximum. A large percentage of them named 30s. to 35s., and the references and experiences which many of the writers were able to give satisfied me that there are a large number of deserving and capable men seeking employment. From my own experience I am quite sure many people are refraining from starting a motor-car on account of the cost of running it, and are imbued with the idea that it is necessary to pay £3 or £4 a week for a competent driver; and I think that your readers and the trade will be served a good turn by having this idea dissipated. Speaking from personal experience, I would strongly advise a beginner to do everything for his car himself for at least a month. It will add to his interest in it and enjoyment of it hereafter, and enable him to judge more fairly of the capabilities of his driver, besides saving many pounds a year in running repairs. If it is impossible, owing to professional or business duties, to give this personal time and attention at the outset, I would strongly advise him, if he is without experience and knowledge, to frankly admit it to his driver rather than attempt to hide his ignorance, which he will not succeed in doing for many hours. If he deals thus candidly with his driver he will gain both confidence and respect, and when difficulties in the running of the car arise he should make a point of knowing the why and wherefore, and to watch his driver put matters right. However ignorant the owner may be at the outset, he will very soon learn and be able to judge for himself whether his driver is competent or not from the manner in which he goes about his work, and the results attending it.

With regard to the vexed question of remuneration, from £2 to £3 a week is not, in my opinion, an excessive remuneration, if a skilled mechanic is required, who can be trusted with an expensive, high-powered, and possibly complicated, car, which will require not only careful driving, but most watchful attention if breakdowns, and possibly serious accidents, are to be avoided. But the great future for drivers as a body will be on cars of lower power, varying from the single cylinder engine of 6-h.p. to the two or four cylinder car of 12-h.p. or 15-h.p.

I am convinced that a driver, if single handed, should not be expected to make himself *generally useful*. Any off days that he may have will give him the opportunity for many necessary details of adjustment, overhauling, etc., as well as keeping his motor house in a fit and proper state; and, personally, I am glad in my own case for my driver to have (especially after wet weather) one or two off days, to enable him to go more thoroughly over his car than would otherwise be possible. There are many people who would gladly start a small one or two-cylinder car if they could be sure of getting a conscientious driver to keep it running for a wage of 25s. or 30s. a week, and I believe that this pay will now secure thoroughly competent and conscientious drivers for a car of this type. If, however, the owner wishes to have his car out early and late, Sundays included, as many owners do, this pay would not be adequate. There is moderation in all things to be observed if results are to be satisfactory, and this applies to motor-cars and their drivers. The employment of drivers is now becoming so much more general that the terms and conditions of employment will soon be as well understood and recognised as in any other branch of employment. Many of those who responded to my advertisement are undoubtedly most worthy and reliable men, and I felt quite sorry for some of them, as, reading between the lines, they are evidently only too anxious to get employment, and prepared to serve their employers faithfully and well. I can assure those of your readers who are hesitating as to starting a motor on account of the question of driver's salary that it is now a matter of selecting a suitable man for the work to be done. The services of a highly skilled mechanic-driver, capable of managing most costly and intricate cars, would be thrown away if engaged to look after a little single 6-h.p. car, and on the other hand the man capable of doing this, and doing it well, for a moderate salary, would doubtless be unequal to the other class of work. The sooner this can be generally understood by the public at large the better for them and the motor trade generally.—Yours truly,

MODERATION.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have read with interest your correspondence under the heading of drivers. May I express my opinion? Owners should beware of the certified driver who leaves the car broken down on the road and cannot rectify it unless a man is sent down from the works to put things right, etc. Owners, when engaging a driver-mechanic, should go into the previous career of the man they engage. I know of a man who has been a groom all his life, and is now advertising for a driver-mechanic's berth.—Yours truly,

MISS FIRE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have followed the interesting correspondence about drivers, and I notice several letters from capable and competent men who are seeking berths, but are unsuccessful, as they cannot get "decent" wages. Nobody has, however, mentioned what wages would be considered "decent," by such a driver-mechanic. As one who is contemplating purchasing a car, and who would like to employ a really competent driver, I write this letter to ask what wages these men expect, as I am sure most of your readers will be interested in the replies.—Yours truly,

A. L. R.

MERCEDES CAR.—Mr. D. M. Weigel writes:—"I noticed that at the Automobile Show held at the Agricultural Hall 18-h.p. Mercedes cars were being termed 18-28-h.p. It is the first time to my knowledge that I have heard of a nominal 18-h.p. giving off 10-h.p. more than it was originally designed for. The fact of the matter is, these 18-h.p. cars are 18-24-h.p., and there is a new car that is 24-28-h.p. The cylinders of the latter have far bigger dimensions than the 18-24-h.p. The cars that are being put on the market this year by the Cannstatt Works are as follows:—24-28-h.p., 32-34-h.p., 40-45-h.p., 60-h.p.

"DICTIONARY OF MOTORING."—Replying to S. H. Waite and other enquirers, this is published by Messrs. Mecredy, Percy and Co., Limited, 34, Lower Abbey Street, Dublin.

INSPECTION PITS.—K. H. H. writes:—"Being about to construct an inspection pit in my motor house, I should be glad of any information as to suitable dimensions. Perhaps some of the readers of the *Journal* who have had such pits built will be kind enough to give others the benefit of their experience through your columns."

ALCOHOL AS A MOTIVE POWER.*

By W. R. Ormandy, D.Sc.

Most of you must be aware that the chemical industries in this country are large consumers of alcohol, and many of you will also probably know that they would be so in a far larger degree if conditions were made more favourable. Messrs. Jos. Crosfield and Sons, Limited, of Warrington, themselves large users of alcohol, have naturally taken considerable interest in this movement, and, with the view of obtaining information for the express purpose of assisting it, they have sent members of their staff to the various continental countries where alcohol is used in quantity for chemical and technical purposes. In considering the information which has been collected during these investigations, it has been borne in upon Dr. Markel, the managing director of this firm, that although the quantity of alcohol used by the chemical industries is not an inconsiderable amount, still by far the largest consumers of alcohol on the Continent are undoubtedly those industries connected with the development of power, light and heat. So much has he been impressed with this fact that, although when first the matter was gone into it was not intended to devote any considerable time or energy thereto, yet, from a comparatively superficial study of the statistics collected, the national importance of this subject acquired such prominence, that he advised, and the firm decided to go much further in their investigations, and to strive for the co-operation of all those societies or firms who are, or might be, directly or indirectly interested in the production, use, or distribution of technical alcohol. To prove that the technical use and the chemical use of alcohol are not by any means synonymous, it is only necessary to refer to the case of Germany, where, although admittedly the country where chemical industries requiring alcohol are most highly developed, the amount of alcohol consumed for technical purposes is one-third, while that used in the chemical industries amounts to but one-fifteenth of the total production. I myself collected for the firm a considerable portion of the information which we now have at our disposal, and I was very much impressed by the ever-increasing quantities of alcohol which are being used in Germany for motive purposes, and as a source of light and heat.

During the course of a conversation with Dr. Boverton Redwood, the possibility of presenting this information to the members of the Automobile Club was raised, and Messrs. Crosfield were only too pleased to have such an opportunity of enlisting the sympathies of so powerful a body.

Owing to the relatively high price of the unsuitable methylated spirit sold in this country few attempts have been made to utilise it as a fuel in internal combustion motors. We have, therefore, to go to the Continent for our information with regard to the subject, and although the use of alcohol in motor-cars has perhaps made more progress in France, yet the quantity of alcohol used as a fuel for motors in Germany is undoubtedly far larger than in France, owing to the fact that in Germany alcohol is looked upon more as a fuel for slow running motors of 2 to 30-h.p., which though smaller in number are larger consumers. The first experiments in the efficiency of alcohol-driven motors were carried out in the year 1895 by Professor Hartmann. A motor made by Grob and Co., of Leipzig, for investigation by the German Agricultural Society, was tested as to its behaviour with both petroleum and spirits. The consumptions worked out at 426 and 839 grammes per b.h.p. hour respectively. These correspond to efficiencies of 13·6 and 12·2—the former a fair result for a much more up-to-date petroleum engine. Later in the same year a Körting motor, with a special carburettor tested by Professor Slaby, of Berlin, only consumed 550 grammes per b.h.p. hour—a great advance. From 1897 to 1901 a number of makers constructed motors for use with alcohol which ran on a consumption of 390 to 440 grammes per b.h.p. hour.

If the question be asked why alcohol was so long neglected as a source of power for internal combustion engines when efforts were being made in every direction to find an outlet for the over-production which was taking place, the answer is to be found in a consideration of the relative heats of combustion of this substance compared with those against which it had to compete. It is near enough for our purpose to take the heat of combustion of alcohol as 5,500 and of petrol and paraffin at about 10,250. At first sight it would appear hopeless to compare two such substances as a source of power unless the price of the one possessing lower calorific effect was approximately one-half that of the other. If the value of a fuel were indeed measured by its heat of combustion, this would be the case; but fortunately it is not so. We depend rather on the number of calories which can be converted into work. In this respect it is interesting to follow the gradual development of German alcohol gas-engine production. The solitary specimen above referred to showed at a brake test such a consumption that the efficiency was approximately 12½ per cent.—that is to say, 12½ per cent. only of the heat units conveyed into the machine were given out again in the form of work. If we compare with this the results of the comparative tests of the alcohol-driven gas engines entered in 1902, in the competition for the prize offered in that year by the German Agricultural Society, we learn what astounding progress has been made. Out of the ten machines entered in this competition no less than three gave efficiencies of from 32·7 to 30·9 per cent. when working on full load. This is an astonishing result, and it places the alcohol motor very high in the list as an economical machine for the conversion of heat into work. I think it would be worth while to look a little more closely into the results of the examination of the motors entered in this competition. These were carried out by Professor Dr. Meyer, of Charlottenberg, and are published in volume 78 of the "Arbeiten der Deutschen Landwirtschafts-Gesellschaft." It must certainly be of interest to learn as far as may be to what these extraordinary results are attributable. In the first place, it is worthy of note that the degree of compression which was used, though very variable, was on the whole very much higher than that which it is customary to use for petrol-driven motors. In some cases a compression up to 10½ atmospheres was used, and the greatest explosion pressure attained was in a number of cases as high as 33 atmospheres.

In order, so far as possible, to make the comparison between the various motors a fair one, Professor Meyer reduces the consumption of alcohol per b.h.p. hour to a basis of compression of 8; that is to say, the clearance space in the motor was one-eighth of the total volume in the cylinder and clearance space together at the end of the suction stroke. This calculation is carried out by making use of certain assumptions with regard to the specific heat of the mixture, which, though not strictly accurate, are sufficiently near for the purpose in view. As showing that the numbers thus calculated are approximately correct, the following case is cited—that a Deutz motor, working on a compression of 5·91, showed a consumption of 436 grammes per brake h.p. hour. If this be converted to a basis of 8·9 compression (which was that actually used in the motor tested in 1902), the consumption, according to the calculation, should be 377 grammes, whereas the actual amount used was 364. The agreement is at least sufficiently near for the purpose in view. From this it would seem that the higher efficiency of the alcohol motor in due almost entirely to the high compression which can be used. We may ask ourselves, then, how comes it that this compression can be used in the case of alcohol and not in the case of petrol? During the compression of a mixture of any fuel as vapour and air, heat is given out, and at a certain point the temperature attained by the mixture is such that explosion takes place. This point of automatic explosion fixes the absolute limit of compression which can be used. If the compression be carried beyond this point we get what is known as pre-ignition, that is, an explosion before the piston has reached the end of the compression stroke. Now the temperature which a mixture of gases attains upon compression depends largely upon the specific heat of the substance in the mixture. In the case of petrol this is very low; in the case of alcohol it is very much higher, and we have also to bear in mind that the spirit used in these experiments contained 10 per cent. of its volume of water. That the influence of water is to allow of a very much higher compression is shown in the case of the Banki motor, where by injecting water along with paraffin, compressions of over ten atmospheres were attained with safety, whereas without the water from four to five atmospheres is the permissible safe limit. A still more striking testimony as to the influence of water vapour in reducing the ignition point of explosive mixture of gases is shown in the case of the new Voigt motor, where, using coal gas and air in the presence of steam, it was found necessary to produce compression pressures of twenty-five atmospheres before self-ignition took place.

A study of Professor Meyer's work certainly leads to the conclusion that the increased efficiency of the alcohol motor is entirely due to the increased compression employed, and the possibility of employing this compression is due, in the first place, to the low inflammability of alcohol air mixtures, but, in the second place, and in a higher degree, to the water contained in the alcohol. The question might be raised: Why not use more water and a higher compression? This has been tried, and Mr. Exner, of Vienna, has been able to prove that by so doing there is an increased efficiency. Professor Meyer has shown that the addition of further water without a corresponding increase in compression has a disadvantageous effect. The maximum pressure of explosion is reduced, and the combustion is diminished in velocity; indeed, with a certain excess, the diagram points to comparatively slow burning rather than to an explosion. This latter result, obtained by Professor Meyer, goes far to prove that the increased effect is in no wise due to the presence of water after the explosion has taken place, and this is, moreover, what one would expect on theoretical grounds.

The statement of Mr. Griffin with regard to the 50-h.p. hydro-oil marine engine built by the Griffin Engineering Company, of Bath, and referred to by Captain Longridge in *The Engineer* of August 7th, 1903, that "during combustion the water vapour is decomposed and burnt in combination with the oil vapour, the added heat of the burning water-gas serving to effect the complete combustion of the whole of the heavy hydrocarbons of the oil," is not borne out by Professor Meyer's results, and when we consider that the amount of heat necessary to split up the water is exactly equal to the amount which can be given out on the re-combination of its elements, it is not astonishing that this should be the case. It is true that by increasing the compression we may use alcohol containing an increased percentage of water, and at the same time obtain better useful effect from the fuel, but the percentage gain, which is attained by compressions beyond 10 or 12 atmospheres, is so small that the greater uncertainty of ignition which accompanies it, and the added expense of constructing motors to withstand the accompanying high maximum explosion pressure, more than counterbalance it.

If the above conclusions are correct, the generally received idea that a petrol motor can be converted into an efficient alcohol motor simply by altering the carburettor is proved to be fallacious. It is true that the conversion of alcohol into a state fit for explosion requires other means than in the case of petrol. This is obvious, when we consider that the heat required for the evaporation of alcohol is about two and a-half times as great as that for petrol, and we have further to bear in mind that there is 10 per

* From a Paper read at the Automobile Club on Thursday, March 24th, 1904.

Digitized by Google

cent. of water present, requiring five and a-half times the amount of heat to evaporate it, compared with an equal weight of petrol. At first sight it would seem that this would be a serious difficulty in the utilisation of alcohol, but if we calculate the actual amount of heat which is necessary to evaporate a certain quantity of alcohol containing 10 per cent. of water, we find that it amounts to only 5½ per cent. of the total heat of combustion of that same amount of alcohol (in calculating the heat of combustions, in all cases it must be understood that the heat which would be given out by the water vapour in the products of combustion condensing from the form of steam is not taken into consideration). This 5½ per cent. of heat necessary to convert the alcohol into vapour can readily be abstracted either from the exhaust gases of the motor or from the water taking away heat from the cylinder walls. We have here some resemblance to the chain of operations taking place in a modern blast furnace, where the exit and once waste gases from the furnace are now used to heat up the air fed to the bottom of the same, or in the case of a Siemens regenerative furnace, where high temperatures and great economy are attained by a similar means.

By making use of the saturation equivalents of alcohol and water for air at various temperatures, it is possible to find out to what temperature the in-going air into the carburettor must be heated in order that the mixture of air, alcohol, and water passing into the cylinder may be such that there is no necessity for any of the constituents to be in a state of suspension as liquids. We find that it is only necessary that a temperature of 190 deg. Cent. should be attained. This comparatively high temperature is only required when the mixture entering the cylinder is to contain the maximum amount of alcohol which the oxygen present is able to fully consume, and this, I need scarcely point out, is a state of affairs which it is not desirable to have. It is in all cases preferable to work with an excess of air, in order to make sure that combustion shall be as complete as possible. Of the ten motors entered for the competition before referred to, Professor Meyer found that the one which worked on the poorest mixture with the most economical results would require the in-going air to the carburettor to be heated to a temperature of 125 deg. in order to carry the alcohol and water in the form of vapour.

The above calculations are carried out on the supposition that the air which is used to start with is saturated with water vapour at a temperature of 15 deg. Cent., a state of affairs not often attained even in this climate. It is also easy to prove, in those cases where the air is not warmed prior to entering the carburettor, that it is only necessary to heat the mixture of air and alcohol spray to a final temperature of 30 deg., in order to attain complete evaporation of the liquid; that is to say, contact of the sprayed mixture with a sufficiently large surface at or over 35 deg. Cent. to evaporate the liquid, and to give the mixed vapours a final temperature of 30 deg. Cent. is all that is necessary. This, I am sure you will admit, is something which is quite easily within the bounds of possibility.

We may take it that the most economical results will be attained by a carburettor which delivers the mixed air and alcohol vapour at a temperature as little as possible above that necessary to retain the alcohol in the form of vapour, because by so doing we shall be enabled to work with safety at the highest possible degree of compression.

I am here not taking into account the possibility of some form of Diesel engine being used for motor-car propulsion. In this form of engine the air employed for combustion is very strongly compressed alone in the cylinder, whereby it obtains a very high temperature, and the fuel is forced in the liquid form into the hot compressed air by an auxiliary pump. By this means efficiency about on a par with that of a good alcohol engine is obtained. On half-load, however, the Diesel engine is more efficient than an alcohol engine. There are grave mechanical difficulties to be faced before this type of engine can be used to replace the light high-speed petrol engine. It is a possibility to be reckoned with, but I am not inclined to think the problem will be solved in the near future.

A necessary consequence of this is that the inlet valves and induction tubes should be made as wide as possible, in order that the diminution in pressure which is bound to take place on the suction stroke shall be as small as possible, otherwise the expansion produced will lower the temperature, cause the fuel to separate in the liquid state, and reduce the uniformity of the mixture. This also points to the probable superiority of the M.O.V. as compared with the A.O.V.

In building motors to work with these high compressions where the explosive mixtures are heated up almost to their self-ignition point, it is especially necessary to design the cylinder in such a way that equal cooling of the walls takes place. One hot projection, or extra hot surface, however small, would determine the compression which could be safely used, and so regulate the thermal efficiency. Similarly the admixture of spirit and air should be as intimate and as cool as possible, because, other things being equal, the pressure and temperature of self-ignition is lower, the hotter and richer the original mixture.

Another circumstance which plays a considerable role in the efficiency of spirit-driven engines has been proved by Mr. Fehrmann to lie in the temperature of the water employed in the cooling jacket. It will be readily understood from what has gone before that the sudden introduction of the air saturated with alcohol and water into a cylinder with very cold walls will have the effect of condensing the fuel and leaving a poor mixture, and such is indeed the case. It has proved impossible to run some alcohol motors with their water jackets supplied at a temperature of 0 deg. C. The great importance of this point, however, was not understood until Fehrmann showed that the amount of alcohol required in some cases to drive a motor on half load was 100 per cent. more when the water in the cooling jacket was kept at about 15 deg. C. than when the jacket was kept at 100 deg. C. This is a subject of very great importance, and all tests of fuel consumption in alcohol motors which do not take this into account will be of little or no scientific value.

A further interesting point brought out during the trials of the ten motors was the influence of varying strength of mixture on the consumption. Thus a motor nearly at full load, working on fairly weak mixture, and giving only 2·3 per cent. misses on the hit-and-miss governor would have a certain consumption, whereas with the same load on richer mixture with a larger percentage of misses the consumption in some cases was as much as 16 per cent. higher, and this behaviour is not characteristic of spirit motors only, for Professor Meyer has observed the same thing in paraffin engines, where in one case the increase in consumption on the same load reached 24 per cent.

With regard to the general comparison of the properties of alcohol as a power-producing substance for motors, compared with petrol, we may point out that the combustion of alcohol in the motor under full load is practically complete, and that the products of combustion are odourless, or nearly so. It has been stated that during the explosion of mixtures of alcohol and air, acid substances might be formed which would have a deleterious effect upon the substances of the cylinder and the valves. The Experimental Fermentation Institute, at Berlin, have alcohol motors which have been running for years, and in no case have any signs of such action been observed. Only in the case of a small motor, which is frequently running on very light or no load, it was found that the exhaust pipe was slightly sooted, owing most probably to the low temperature which obtained, and the consequent incomplete combustion.

In concluding this part of our subject we may say that, in so far as alcohol is less volatile, and has a higher ignition temperature, it is much less likely to be a source of accidental fires. Its storage need not be subject to the same stringent regulations, and in its carriage it is not subject to the same severe restrictions. It is more pleasant to handle than either petrol or paraffin; it is homogeneous, which is more than can be said for the present supply of petrol. The composition of the later supplies of petrol is becoming

The Winton "Bullet" Racer at Ormonde, Florida.

more and more heterogeneous, and there is an ever-growing percentage of high boiling point constituents, which will do their part, no doubt, towards adding to the unpleasant smell of the effluent gases and in diminishing the already poor efficiency of the petrol engine. An ideal liquid for a carburettor should have a fixed boiling point, then the instrument can be properly arranged for the work it has to do.

If care be taken that the carburettor passes the increased quantity of air necessary for the oxidation of benzol compared with alcohol, and that the temperature of the fluid in the cylinder jacket is kept constant, it would seem that, *at any given compression*, equal efficiencies are obtainable, but the allowable compression is less the greater the addition of benzol.

That alcohol is not only a suitable motor fuel, but that in most respects it is the most suitable, is shown in the foregoing, and if further proof were needed as to its practical possibilities it can be gathered from the records of those French automobile trials in which alcohol was used, and of which I would recall the consumption trial through Amiens, Arras, Abbeville and back to Paris, wherein nineteen heavy cars, sixteen light cars, six voiturettes, and six cycles competed. The distance of 453 miles was covered in about twenty-three hours on a consumption of 20·85 gallons by one car, and in 26½ hours on 18¼ gallons by another. Again, Mr. Farman, on a 35-h.p. Panhard, covered 254½ miles at a rate of 52·2 m.p.h., using alcohol as a fuel.

It is true that the results we have been considering were obtained with engines of only 200–300 revolutions per minute, but there is no reason to believe that an increase of revolutions would materially alter the conclusions we have drawn—especially if motor constructors would bear in mind the advisability of trying a somewhat greater ratio of stroke to bore than obtains in petrol motor construction in general. (This average ratio in the motors tested by Professor Meyer was 156 : 100, and the motors giving the best results were constructed to approximately these dimensions.)

The average user of a motor does not ask what proportion of the heat value of a certain fuel is obtained as work, but rather what does it cost in

Digitized by Google

fuel to obtain a certain amount of work, and this question we must now consider.

From what has gone before we know that petrol and alcohol stand in the ratio of 2 : 1 as regards their heat of combustion, but that in the case of alcohol 30 per cent. of this heat is obtainable in the form of work, while in the case of petrol only 20 per cent. can be so obtained.

We require, then, four parts of alcohol or three parts of petrol by weight to yield the same amount of heat in the form of work. Taking petrol at 1s. 3d. per gallon—price quoted the writer in Hamburg for quantities of 30 gallons—and allowing for the different specific gravities, we should have to buy alcohol at 1s. 2d. per gallon to place them on an equal footing as yielders of power.

The comparison between paraffin oil and alcohol, taking their relative efficiencies at 15 per cent. and 30 per cent., shows us that these two would have to be sold at the same price to give equal economic results. From now up to the end of 1908, motor alcohol containing 10 vol. per cent. of water is to be had in Germany, delivered at the nearest railway station, at 9d. per gallon, in lots of not less than 1,500 gallons, and at 10d. per gallon in lots of 40 gallons, cask free, but returnable. To buy in quantities such as a pint, at retail dealers, it costs at the rate of 1s. 3d. per gallon, at which price it is still cheaper than petrol at 1s. 6d.—by no means an unusual price in England.

The problem of supplying motor fuel at a price which will not only render it cheaper than petrol, but which will enable it to compete with paraffin oil, has been solved in Germany.

What are the conditions in England? Buying methylated spirit in quantity, we can obtain it at 1s. 11d. per gallon, and when obtained it is not so suitable as a fuel either for motors or lamps as is the cheaper German spirit.

Consider that alcohol as a motor fuel is free for the most part from the objections urged against petrol; that it is, of all extensively-used liquid fuels, the most nearly ideal; that it is sold by the million gallons on the Continent for technical purposes as a source of light, heat, and power; then ask, why cannot we obtain it in this country at a similar price?

The answer is, that our present laws and our system of taxation render it impossible.

In consequence of the disadvantages legally imposed on the British distiller, there is a tax on imported alcohol equal to about 9d. per gallon of 90 per cent. strength—a so-called "differential duty." Put into plain language it means that we pay 70 per cent. to 100 per cent. more for our spirit than we should do if this tax, which has well been called "a bargain for hindrances to free working imposed by law," were not imposed.

It must be fully understood that our complaint as to the influence of this tax relates only to spirit to be denatured and used for industrial purposes. Potable alcohol must be regarded from an entirely different standpoint.

Time is too limited for me to go at length into the question of German as compared with English law in regard to alcohol, either as to production, distribution, or use. This in itself is more than subject for a lecture, but I may inform you that although the German Government showed forethought for the chemical industries, they had taken little action as regards legislation concerning alcohol for other technical purposes—heat, light, or power—up to the year 1887. At that time commercial alcohol generally cost, retail, at the rate of 3s. 6d. to 4s. per gallon. Since then note the change! There is scarcely a village in the whole land where alcohol of guaranteed strength 90-95 per cent. cannot be obtained retail at 1s. 3d. to 1s. 4½d. per gallon. At this price it can be bought in stoppered bottles just as we are accustomed to buy mineral waters.

Although I cannot deal at length with those phases of the German law which have called forth such a notable change, I can, by means of a few statistics, make evident the enormous importance and size the traffic in technical alcohol has attained, and in some ways compare our own position therewith. In the year 1900–1 Germany produced 406 million litres (about 4½ litres = 1 gallon). Of this 112 million litres were used for technical purposes. In the same year England's consumption of technical alcohol was 13 million litres. Please note that this total quantity of 13 million litres is a little over half the amount used by the German chemical industries, and about two-thirds of the quantity used in the manufacture of vinegar per annum.

The consumption of spirit for technical purposes has grown from 71 to 112 million litres in six years; our consumption in the same period grew from 9 to 13 millions. If we progress at the same rate, and Germany stands still, we shall be equally large consumers in the year 2064.

In Germany they have incandescent lamps of from 20 to over 1,000 candle power, cheaper by half to keep up than paraffin lamps, even with spirit at 1s. 1½d. per gallon. Professor Dr. Wittelshöfer, of the Central Society for the Distribution of Alcohol, in his annual address to the members of the Society of Alcohol Manufacturers in 1903, told them that in the first four months of 1902 they sold 270,000 litres of motor alcohol; in the corresponding period of 1903 they disposed of 800,000 litres.

In the first three months of 1902 and 1903 the number of lamps sold by this one society grew from 7,200 to 17,000.

Not until the Germans have driven paraffin oil out of their market will they be satisfied. As it is, post, army, railway use alcohol for power and light wherever possible. Doubtless the thought that every litre of alcohol so used makes the nation more self-contained has its weight with the Government.

In conclusion, I say that the case for a reduction in the price of alcohol for technical purposes is well established. Cheap spirit would place the rapidly-growing motor industry on a secure basis, because the production of alcohol can be extended almost without limit; it would give our chemical manufacturers a chance of gaining some share of the enormous trade now in other hands. Its production might be made, by suitable legislation, to encourage agriculture, to take back to the land some of the 900,000 workers who have left it since 1851, and give us back that physique in our young men, the loss of which is so bemoaned by the members of the National Service League and so worrying to the War Office.

CLUBS AND ASSOCIATIONS.

EAST SURREY.

THE first annual general meeting of this club was held at the White Hart Hotel, Reigate, on Saturday, the President (Major Kingsley O. Foster, J.P.) presiding. The annual report said it was proposed to have a number of runs during the coming season, and that arrangements had been made with local tradesmen for the supply of petrol, lubricants, etc., at reduced rates. The report was adopted on the proposition of Mr. Bowden, seconded by Mr. Makovski. Major Foster having been re-elected president, the following were elected as vice-presidents:—Sir George Livesey, Sir A. Rendle, Col. Robinson, Capt. Rawson, Mr. H. N. Corsellis, and Mr. J. Underhill. Mr. Barry was unanimously re-appointed hon. sec. and treasurer, and the committee was elected as under:—Dr. Wakefield (Horley), Messrs. J. B. Purchase and F. Ellwood (Redhill), C. H. Whittington (Betchworth), A. Gunning-Keen, H. Hughes, G. H. Bowden, and A. Macaire (Reigate), N. Colman (Epsom), J. Underhill (Warlingham), and G. W. Whitingham (Earlswood). Major Foster and Mr. Purchase were nominated as representatives on the General Council of the A.C.G.B.I., and Mr. Barry and Dr. Wakefield as representatives to the General Committee of the Motor Union. Mr. Makovski was re-elected hon. auditor, and Mr. C. Grey was appointed official repairer to the club. Rule 18 was amended so as to allow ladies to become members. The first lady elected was Lady Beatrice Rawson. It was agreed, on the motion of Mr. Bowden, that a small honorarium be given to Mr. Barry (hon. sec.) for the hard work which he has done for the club during the past year. The meeting then terminated.

HUDDERSFIELD.

AN enjoyable smoking concert was held at the Imperial Hotel, Huddersfield, under the auspices of the local branch of the Yorkshire Automobile Club. The chair was occupied by Mr. Alec Mallinson. Mr. E. Gordon Learoyd, the secretary, explained that the object of the gathering was partly of a social nature and partly to explain exactly what the club had done up to the present and what was the intentions of the committee for the season. Mr. Joseph Crowther had accepted the office of president. There were advantages to be gained from joining the club, for they became affiliated not only with the Yorkshire Club, but with the Motor Union in London. The Yorkshire Club gave facilities in this way—when they visited other places where there was a branch they could use the club rooms, and could also have their machines stored. The Huddersfield Club would have to give similar advantages. The main thing they had done up to the present was with reference to the speed limit. The Huddersfield Corporation wanted to restrict the limit to seven miles per hour within one mile from the centre of the town, and ten miles per hour within two miles from the centre of the town. They did not think that seven miles was warranted in Huddersfield at all; in fact, they did not think that ten miles was necessary. Huddersfield, unfortunately, was a somewhat deserted town so far as traffic was concerned. The committee of the club had sent up their objections and they hoped they would have good effect. In one of their objections they stated that they were anxious to refrain from driving at an excessive speed, and would in the future, as in the past, have great regard for the safety of persons using the thoroughfares. He hoped all members of the club would carry out as far as possible that intention. It was no use objecting to the speed limit if members interfered with the traffic and with foot passengers. They were particularly anxious to show that they were willing to assist the police in looking after the traffic, and if they did that there would be no reason for the proposed limit to be fixed. They had very good hopes that the application by the Corporation would be withdrawn when their objections were seen, but it would not be withdrawn if there was any furious driving in the streets, or if any serious accidents occurred in the meantime.

CASE DISMISSED.

THE charge brought against Mr. Paddon for driving to the danger of passengers on the highway, and which has been before the West London Police Court several times, has now been dealt with. It appears that Mr. Paddon was driving a motor-car along the High Street, Kensington, when it knocked down a lady, who was crossing the road, and ran over both her legs. Fortunately, she was not seriously injured, but the police proceeded against Mr. Paddon on the above charge. After hearing a large number of witnesses and arguments deduced by Mr. Staplee Firth, the case was dismissed.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

EVIDENTLY the people of the Isle of Man are taking the forthcoming eliminating test in good earnest, and already there have been some claims put forth by the lesser towns, that they should be made the headquarters for the event instead of Douglas. It is not likely, however, that any other but the principal town of the island will be regarded as the pivot of organisation, as the time draws near for the event to take place. A guarantee fund has been commenced to meet the local expenses, and it is probable that an attempt will be made to organise some sort of a programme, the great race forming, of course, the central feature. Hill climbing competitions in the neighbourhood of Ramsey, and speed contests, probably at Douglas, are already contemplated, and it is evident that motorists who go to Mona in May will have no likelihood of scanty fare.

◆ ◆ ◆

Colonial Advance.

ELSEWHERE we record the opening meeting of the Automobile Club of Victoria, and, in accordance with custom, when chronicling the inaugural run of a Colonial club, we give the report all the glory of large type. The development of automobilism in the Colonies has been very rapid, and already the names of British-made machines are beginning to appear in the records of meets both in South Africa and in Australia. This is very gratifying to those anxious to see our motor-car makers in the forefront of the international trade.

◆ ◆ ◆

Alcohol as a Motor Fuel.

FOLLOWING on the paper by Dr. Ormandy in last week's *Journal*, Lieut.-Col. Holden, the chairman of the A.C.G.B.I., gives the following statement as regards the motor-car user's ideas of his requirements in the case of an alcohol fuel. It should be such:—(1) That the substance used for denaturing should preferably not be inert, but should add to the energy latent in the fuel. (2) That in any case the denaturing substance should pass away with the products of combustion, and not be liable to leave any objectionable residue in the cylinders, valve chambers, or on the valves or seatings, passages, &c. (3) That the mixture should be explosive over as large a range as possible of proportion of gas to air, and should not be inferior to "petrol" in this respect. (4) That ignition should be readily effected under the condition of variable compression consequent upon the present system of governing by the throttling of a mixture of constant proportions.

◆ ◆ ◆

Motor Ambulances.

AT the recent exhibition at the Agricultural Hall, London, some members of the Metropolitan Asylums Board attended to ascertain the likelihood of motor ambulances being successful in ousting the old-fashioned horse vehicle. Of course in the great cities where hospitals and infirmaries are centrally located the question is not so pressing as in cases where hospitals are far away from the populous places. There are scores of small towns in the country that have hospital arrangements where a motor-ambulance would prove of great utility in saving suffering and adding to the chances of recovery of those meeting with accidents. We understand that attention is being given the subject by several authorities, and probably the co-operation of motoring experts with medical men might result in a practical form of motor-ambulance for this country.

◆ ◆ ◆

Motor Wagon Essentials.

MR. DOUGLAS MACKENZIE, who has had much practical knowledge of the heavy motor traffic question, has given some useful suggestions to the Departmental Committee on Motor Cars as to what he regards as the requirements of the users of motor wagons. A greater weight unladen than six tons is not necessary, in his opinion, and it would be more satisfactory if two tons were allowed for the trailer tare. He would like to see the limit fixed, not on the basis of the tare weight, but on the total load carried by any one axle. If this were limited to ten tons—the weight on the hind axle of the larger wagons when fully loaded—there would be a definite load which all road and bridge authorities would know they must provide for. Regulations with regard to the size of wheels and the width of tyres should be framed to encourage the use of wheels of increased diameter, which not only did less hurt to the road surfaces, but also reduced the tractive effort required. As to speed, Mr. Mackenzie believes that not less than five miles per hour should be imposed. He would abolish the speed limit altogether, leaving it to the user of the vehicle to see that it was driven at such a rate as not to inconvenience anyone, or to run at such a pace as would result in excessive wear and tear. On this latter point the business instincts of the user would be sufficient check.

◆ ◆ ◆

Reunion of Provincial Clubs.

FOLLOWING upon their successful combined meet of last year, some of the provincial clubs will again assemble at Buxton in June for what is apparently becoming an annual function. So far the Manchester, Liverpool, Nottingham and Sheffield Clubs have signified their intention of taking part in the event, for which only fine weather has yet to be arranged to ensure a repetition of last year's success. This idea of combined meets of the provincial clubs is one to which every encouragement should be given. It widens the experiences of motorists who might otherwise have a tendency to become somewhat local in their knowledge of automobilism and narrow in their views of the points and performances of cars. The interchange of opinions which results from these combined meets is a valuable feature to be remembered in estimating their utility.

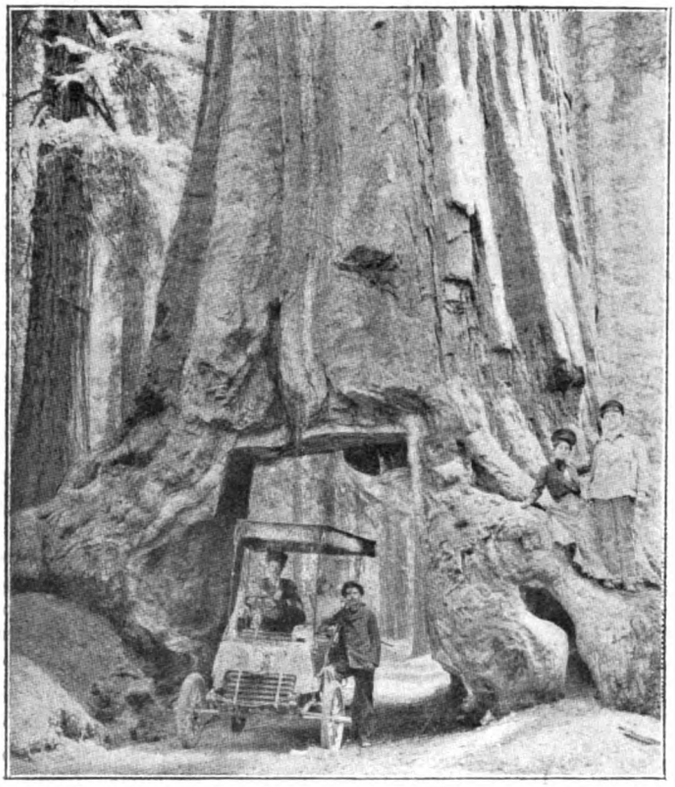
The Glasgow to London Reliability Trial.



WE would remind intending entrants and manufacturers generally that the last day for receiving entries for this Trial, which is being organised by the Western Section of the Scottish Automobile Club, without increase of fees, is Wednesday, the 18th inst. We understand that the entries to date are most satisfactory. The corresponding Trial of last year

Digitized by Google

was, it will be remembered, a most successful event, and attracted throughout both England and Scotland a large amount of public attention. Entries should be lodged with Mr. R. J. Smith, 59, St. Vincent Street, Glasgow, the Honorary Secretary, from whom the necessary forms and copies of the conditions may be obtained.

Motoring in California.

THE famous big tree groves of California, all of which are rather inconveniently situated in regard to transportation facilities, are among the many natural wonders which it is now easy to visit with the motor-vehicle. There are good roads to nearly all of these groves, but the distances are considerable, and the uncertainties of coach service, as well as the slow time made by the horse-drawn vehicle, deter many from taking a trip to these wonderful points of interest. The grove most difficult to reach is that between Wawona and the Yosemite Valley, fifty miles distant from Raymond, the nearest point by rail. The precipitous mountain grades *en route* have been the undoing of several pioneer motor enthusiasts, but

[*Motor, New York.*

latterly, as more modern machines essay the climbs, the grades succumb with monotonous regularity. The latest successful trip to the Yosemite by automobile was accomplished by Major Fulmer, of Los Angeles, Cal. The illustration shows Mr. Fulmer and his wife standing at the base of one of the most famous trees in the valley. The tree, which is a typical *Sequoia gigantea*, is reported to be about 2,000 years old, is 35 feet in diameter and nearly 400 feet in height. The opening through it was cut a number of years ago to provide a startling feature of the then new coach route.

A Motor Pocket Book.

A SECOND edition of the Motor Pocket Book brought out by Messrs. A. Constable and Company, Limited, will enable the editor, Mr. Mervyn O'Gorman, to supply some omissions which are conspicuously apparent in the first issue. The plan of the work is alphabetical, short descriptions of the parts of motors being given to the extent of nearly four hundred pages, together with much information of a practical character. French and German terms are also included, and, on the whole, the volume will prove useful to motorists who do not read the automobile press with persistent regularity.

Mr. Staplee Firth.

TWO more wins are to be credited to Mr. Staplee Firth, whose police-court trophies are becoming as numerous as the scalps that decorate the banqueting halls of the most redoubtable Redskins. The effect of recent defences he has made will be to make the police chary of summoning motorists, for fear that the plucky little fighter of the Motor Union may face them in the police-court. Mr. Firth's dictatorial methods when before magistrates attempting to browbeat, and his pitiless cross-examination have not always been understood by the lay reader. But they have been justified in the results, which have been uniformly satisfactory to the motoring defendants. Of course, Mr. Firth has had the advantage of practical acquaintance with automobilism in preparing his cases, and the knowledge gained on the car has often proved useful in the court. Magistrates are learning to appreciate his reading of the law, and to recognise that in his citing of cases and of the Acts concerning motoring he speaks with authority. Altogether motorists are fortunate in having such a legal adviser.

Police Evidence.

THE possibility of the police making mistakes is a fact which is steadily forcing itself upon the minds of magistrates, and although they are naturally loth to accede to applications for summonses against constables, their changed attitude is significant and should be a warning to police officers generally. This has lately been clearly indicated in cases heard at the South and also the West London Courts, where evidence has been given by the police which has excited the indignation of the defending counsel to such a degree that suggestions for summonses have been made. The fact that applications of that character are rarely necessary should be enough to secure something like care on the part of the particular officers when next they stand in the witness-box. At Guildford, too, the redoubtable Sergeant Jarrett has lost another case, and the way in which he gave evidence shows conclusively that even such an experienced officer cannot always be sufficiently definite as to what he sees.

The Scottish Attitude.

AT the monthly meeting of the Western District Committee of the County Council of Stirlingshire a letter has been read from the Secretary for Scotland in reference to the restrictions and prohibitions on motor-car traffic the committee proposed to impose. The general view of the Secretary, as set forth in the letter, was that it might be better not to proceed with the restrictions and prohibitions to any extent till it was seen whether other provisions of the Act rendered such a resort necessary. The mere possibility of danger was not enough in itself to justify the restrictions proposed, unless from actual experience it was found that there was danger, despite the caution of an efficient driver. Where there was danger a warning signboard would in the majority of cases prove sufficient. He trusted the County Council would not consider it unreasonable if he asked them to reconsider the whole matter. Meanwhile he thought it was against the general public interest to give his approval to the restrictions proposed. The Chairman said the position taken up by the Secretary for Scotland was that they had first to prove that the precautions laid down in the Act were insufficient before imposing restrictions. That was to say, that before a road could be considered dangerous somebody would have to be killed or injured. They were so situated in relation to Glasgow that their roads were greatly taken advantage of by makers for testing their machines, and in that fact lay considerable danger. However, in making this application they had relieved themselves of the responsibility, although it did not seem that the Secretary for Scotland was willing to assume

Digitized by Google

it, as all he had done was to ask them to reconsider the matter. Several members referred to the care with which the subject had already been gone into, and it was agreed to intimate that the committee could see no ground for altering their proposals, and that they would not consider themselves responsible in the case of accident.

◆ ◆ ◆

Central v. Local Authorities.

THE reply of the Local Government Board to the Holland (Lincolnshire) County Council's application to prohibit motor-car traffic along three of its roads at night time shows that local prejudices are not to be allowed to over-ride national interests. The Board points out that specific evidence of the unsuitability of the roads must be given, and states that it is only in exceptional cases that it will sanction the entire closing of a road against motor-car traffic. We are glad that the central authorities are recognising the importance of the subject and that they are paying little heed to unnecessary applications.

◆ ◆ ◆

Motor-car Mishaps.

THE motoring season which began with the Easter holiday has been ushered in with a series of mishaps which serve as a text whereon to hang another homily to motorists to drive with caution and tour with care. So far as we can learn the accidents have not been caused by any disregard of the law; they have been associated with cars carefully driven and would probably have occurred in some instances had horse-drawn vehicles instead of automobiles been engaged. But every mishap of the kind is exaggerated in the public imagination; hence regard for the progress of automobilism should lead every motorist to be extremely careful lest he should do anything to retard the advance of the motor-car.

◆ ◆ ◆

When should a Motor Driver Stop?

SHERIFF ARMOUR at Cupar has given judgment bearing on the responsibilities of motor-car drivers. The case arose out of a slight accident that occurred near St. Andrews recently, where, owing to a motorist neglecting to stop when a ploughman held up his hand, one of the horses he was driving came down, and a quantity of potatoes from the carts were strewn on the road. Mr. George Cheetham, of Henley Green House, near St. Andrews, was accused of having driven a motor-car to the danger of the lieges on the highway. Mr. W. R. Doull conducted the defence, which was that the accused had exercised proper and sufficient care. He slowed down, and was of opinion that by passing there would be less danger than if he stopped. The Sheriff said he understood that that was a test case, and that the main object was to get a decision upon the question of whether the driver of a motor-car was bound in every case where the driver of a horse held up his hand to stop. As at present advised, he was inclined to hold that the driver of a motor-car was bound if he saw a man hold up his hand on the road to consider that the man was driving a restive horse and wanted him to stop. His Lordship imposed a nominal penalty of half-a-crown.

◆ ◆ ◆

Scottish Caution.

THE County Council of Forfar is still considering the important question as to whether prohibition or restriction shall be their rule with regard to the motor-car traffic in that county. A special committee was appointed by the Council to consider the matter. They met at Arbroath the other day, when it was resolved to recommend to the body that appointed them to prohibit motor-cars on two roads in the Brechin district. It was pointed out at the meeting that this would prove no real hardship to motorists, for places reached by them were easily accessible by other roads in the vicinity. Should the Secretary for Scotland sanction this prohibition, it is to be hoped that the County Council will take care that proper notices are posted sufficiently near these alternative roads to prevent motorists wasting time and temper by having to retrace their tracks for a few miles unnecessarily. A speed limit of ten miles per hour is also desired on passing through villages or in the neighbourhood of schools. Fortunately in the Dundee district no roads are mentioned as being in the restricted area.

The Delivery Van Trials.

THE Bradford Chamber of Commerce has decided to appoint an official Observer to attend the forthcoming trials of delivery vans to be held under the auspices of the Automobile Club. The technical secretary is apparently asking some of the leading chambers of commerce and other important commercial organisations in the country to send Observers who will not only be able to render good service to the Club, but whose presence will be useful in securing local reports to their respective chambers which will go far to popularise motor traffic among the principal industrial leaders of the kingdom. The reception accorded to the proposal by the Bradford Chamber was very gratifying, and every speaker was in favour of that body giving official countenance to the trials in the way proposed. The general opinion was that the Bradford trade would ultimately benefit to a very considerable degree from the introduction of automobile traffic—a fact which the tests should enforce with much authority.

Side Slip Trials.

FOR the side slip trials of the A.C.G.B.I., to be held at the end of April, several interesting entries have been made, including the following:—Mr. Bentley Tollemache: Leather band with steel studs, inside of which are strips of aluminium and corresponding strips of asbestos, etc.; Mr. W. Maitland Edwards: Toughened chrome leather cover, vulcanised to tread, with bifurcated rivets at suitable intervals; Mr. W. Hayes: The Empire B.P. support, fitted to chain and top stays of frame by clips; The Parsons Non-skid Company: The Parsons chain encircling tyres; The Wilkinson Tyre and Tread Company: A tread perforated with wires, to be vulcanised or solutioned on the tyres; Messrs. W. and A. Bates: A non-slipping tread made of rubber, to be attached to tyres by solution, or vulcanised thereto.

An Official Tour in Lakeland.

ACTING in accordance with the provisions of the Motor Car Act, a representation from the Main Roads Committee of the Westmorland County Council, consisting of Mr. J. W. Weston (chairman of the committee), Mr. T. A. Argles, Mr. D. J. Pennington, Mr. J. C. Webster, Mr. Bintley (County Surveyor) and Mr. Rogers (Main Roads Superintendent), made a tour of roads with a view to the placing of danger signals. They were conveyed by Mr. Herbert Croft, on his 16-h.p. motor-car, and Mr. G. Atkinson (Messrs. Atkinson and Griffin, Lancaster), in a second automobile, meeting at Levens Bridge and proceeding thence to Duke Hill, Crosthwaite, Bowland Bridge, Cowmire Hall, Pool Bank, Witherslack, Bridge Inn, Levens Bridge, and Milnthorpe. After an interval the party went on to Arnside, thence to Beetham by Leighton Beck, to Burton, Crooklands, Woodhouse, and thence to Kendal. The route, roughly speaking, covered about a hundred miles.

◆ ◆ ◆

The Exhibition.

PRESS reports of the recent Motor Car Exhibition at the Agricultural Hall, London, continue to reach us, and from "Black and White" of last week we cull the following:—"Credit is due to all concerned for the laudable attempt to make the Exhibition an artistic as well as a commercial success. In surveying the crowded hall from many points of view, one could not but glean the impression that the Show approached more nearly the Continental manner of doing these things than any that has so far been held in this country; indeed, several of the stands were in every respect as fine as the best to be seen abroad. Moreover, the arrangement of the flags and kindred flaunting decorations was such as to harmonise the various colour schemes embodied in the stands. During the daytime the exhibits were seen to better advantage than they were at the Crystal Palace Show, while the lighting arrangements at nightfall left nothing to be desired."

◆ ◆ ◆

The Thomas Hardy and Scott Montagu Country.

AN Easter at Bournemouth is something to be remembered, with the beautiful rides through the lovely stretches of road in the New Forest—now resplendent with Lenten lilies, wood nymphs, and the pale primrose—with its charming bye lanes, overhung with branches of budding bushes. And then again there are the mating birds sending forth their songs heavenwards, hoping, however, their rewards to be less ethereal, but all making the forest glades ring with gladness even as the verdure makes the senses pleased with Nature as the season of spring is felt to be upon us. The Dorsetshire villages and lanes, the former with their cobwalls and thatch, and the latter with their golden gorse-lined hedges; hills and commons purple, soft and sweet in their melancholy, and wild and rugged in their sternness—roads always good. Such an Easter prospect is to be commended, especially should the weather be all that one could desire. There are rides for the motorist here, there, and everywhere, and, should he have such a good time on his car as the present writer, has he will be as enthusiastic in praise of the counties of the gentlemen referred to in the title of this note.

◆ ◆ ◆

Non-Stop Runs.

IN view of the many attempts that have recently been made to break non-stop automobile records, it may be of interest to make clear to manufacturers generally the conditions under which the Automobile Club recognises long distance non-stop runs on the road. The first consideration is that the run shall be an absolute non-stop run of the motor and the car, no stops of any nature whatever being admitted except for traffic purposes, when the motor may be stopped if the driver is called upon to do so, so that any stop, whether for tyres or other purposes, will be considered as the end of the run. Every run must start from the Automobile Club or from the club-house of an affiliated club; and indication of the intended length of the run and the route to be covered is to be given to Mr. Basil Joy, the technical secretary of the Automobile Club at least a week before the date of the run. Accumulators or other parts may be changed and fresh petrol may be picked up and put in the tanks so long as neither the car nor the motor is stopped for the purpose. A fee of one guinea for every 100 miles of the declared run will be charged, with a minimum of five guineas for the purpose of the payment of the Observer, with an additional three guineas as a club fee for 500 miles or under, with five guineas for a 500 to 1,000 miles, and eight guineas for over 1,000 miles.

The Coming Budget.

THE prospects of the Budget are being eagerly discussed in City circles, and the rumour as to the likely imposition of a tax on petroleum has caused some talk. In fact, it was even suggested that oils generally would receive the attention of the Chancellor of the Exchequer. We do not anticipate that Mr. Austen Chamberlain is likely to propose anything so unpopular as such taxation would be. For not only would the industries of the country be affected, but it would be a real hardship to working people to have their cost of household illumination increased to any extent. Certainly any tax on petroleum would be resented by a formidable force of public opinion.

PRINCE HENRY OF PRUSSIA has just acquired a 24-h.p. Benz Parsifal car.

THE Lincolnshire Automobile Club and the Southern Motor Club have joined the Motor Union.

THE Burnley Club recently held a "Hot Pot" at the Bull Hotel, Burnley, with a view to interest unattached motorists in its doings.

THE boroughs of Longton and Stoke-upon-Trent have withdrawn their applications for the imposition of the ten mile limit on motor-cars.

ON Wednesday Mr. C. B. Fry, captain of the Sussex Cricket Club, was presented with a 12-16 h.p. Darracq car in recognition of his services to county cricket.

IT is reported that the Benz Company have withdrawn their entry for the Gordon Bennett race and that consequently no eliminating race for the German team will be held. Two Mercedes and an Opel will now represent the Fatherland in the Cup race.

THERE were two 60-h.p. Mercedes sold at Cordingley's recent Exhibition at the Agricultural Hall, and, curiously enough, both stopped at the Crown Hotel, Lyndhurst, within two hours of each other the same day. It has been said there is a difficulty in starting these cars, but this is a mistake, for, when properly adjusted, they start as easily as any other car.

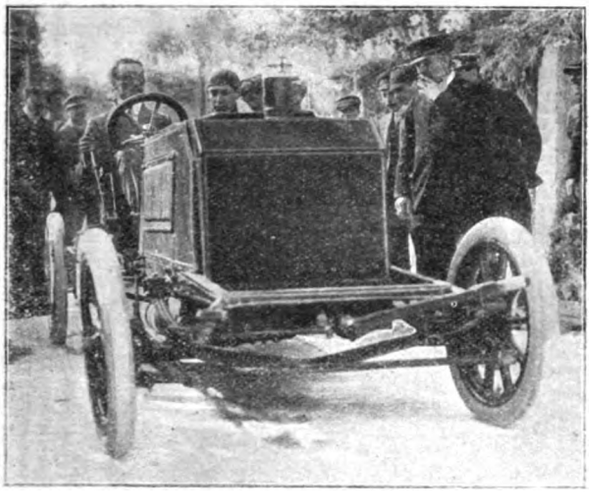
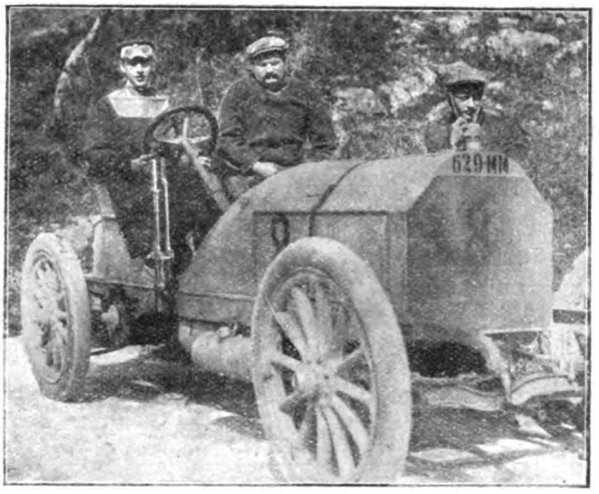
RECORD BREAKING AT NICE.



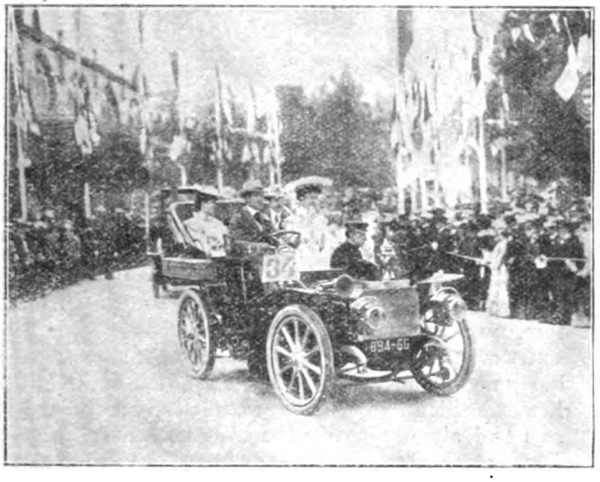
AFTER being postponed on account of rain from the previous Monday, the mile and kilometre races on the Promenade des Anglais at Nice came off on Thursday last week in splendid weather. Chief interest was centred in the heavy car class, in which some marvellous speeds were attained, the honours falling to Rigolly and Duray, both driving Gobron-Brillié cars with engines of about 100-h.p. In the mile trials with standing start these two made a dead-heat, their time being 53 3-5 sec., a new record for the mile, the previous best, by Rigolly, being 58 4-5 secs. Jenatzy, the winner of the 1903 Gordon Bennett race, was fourth, Mr. Mark Mayhew on his Napier racer being seventh. The times for the flying kilometre were also taken, in conjunction with the mile trials. No new times were set up in the light car, voiturette and motor-cycle classes. It is, however, noteworthy that an Italian machine took first place in the last named category. The appended table shows the results.—

CARS FROM 600 TO 1,000 KILOS.



Driver.		Time for Mile. Min.	sec.	Time for Flying kilometre. Sec.	Average speed in kilometres per hour.
1. Rigolly ...	Gobron-Brillié		53⅗	25⅗	140·6
1. Duray ...	,,		53⅘	26⅘	135·3
3. Werner ...	Mercedes		57⅘	30⅘	117·6
4. Jenatzy ...	,,		59⅕	30⅕	119·2
5. Fletcher ...	,,	1	1⅕	30⅘	118·4
6. Braun	,,	1	1⅘	30⅘	117·6
7. Mark Meyhew	Napier	1	3	32	112·5
8. Warden ...	Mercedes	1	3⅘	30⅘	117·6

VOITURETTES.



1. Deletang ...	Passy-Thellier	1	42	55⅗	—

Mr. Mark Mayhew on his Napier Racer.

Mr. Andrew Fletcher on his 80-h.p. Merce .

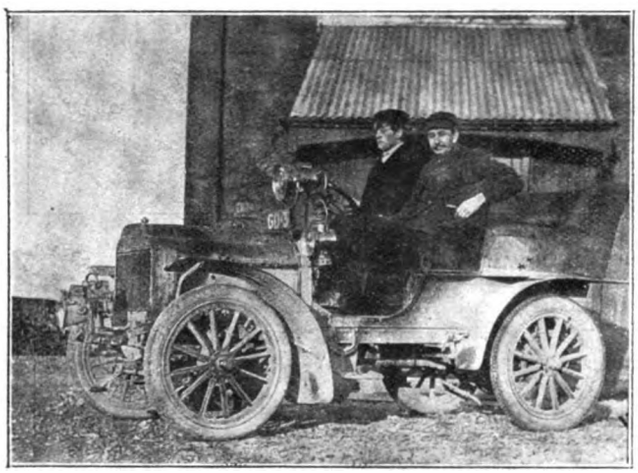
After the mile trials came the kilometre contest with 600 metres flying start, for the Henri de Rothschild No. 2 Cup. This was held by Hieronymus, who last year covered the flying kilometre in 31 3-5 sec., or equal to 113·3 kilometres per hour, and is reserved for cars weighing from 650 to 1,000 kilog. and carrying two passengers. There were seven competitors, two

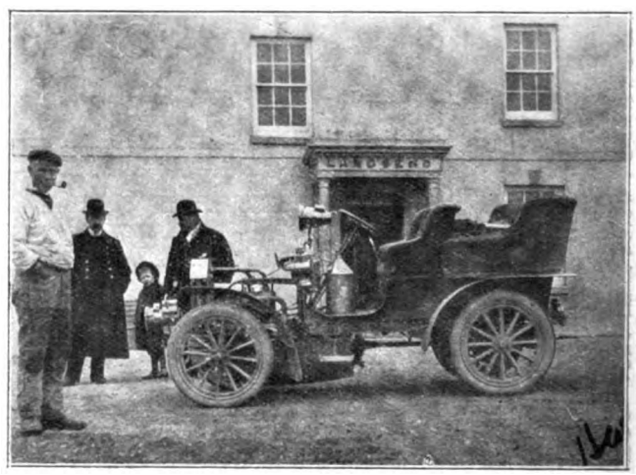
Digitized by Google

Gobron-Brillies, four 80-h.p. Mercedes and Mr. Mayhew's Napier. The event was another success for Rigolly and Duray. Appended are the times :—



HENRI DE ROTHSCHILD No. 2 CUP.

Name.	Car.	Time for Flying Kilometre. Sec.	Average speed in kilos. per hour.
1. Rigolly ...	Gobron-Brillie	24	150·
2. Duray ...	,,	26⅘	135·3
3. Mark Mayhew ...	Napier	28⅘	125·8
4. Warden ...	Mercedes	29⅘	122·4
4. Braun ...	,,	—	122·4
4. Werner...	,,	—	122·4
7. Fletcher ...	,,	29⅘	120·8



Finally came a similar series of trials for the Henri de Rothschild No. 3 Cup, in which the fastest times of the day were recorded, Rigolly passing the post in the new world record time of 23 3-5 sec., equal to 152½ kilometres or over 95 miles per hour. Duray, as usual, was close up behind, followed by Mr. Mayhew, who is to be congratulated on the excellent showing he made with his Napier, beating as he did the Mercedes driven by such experts as Jenatzy, Braun, and Werner. The times of the various competitors are shown below :—

HENRI DE ROTHSCHILD No. 3 CUP.

1. Rigolly	Gobron-Brillie	23⅖	152·5
2. Duray ...	,,	25⅕	142·9

At John o' Groat's.

At Land's End.

3. Mark Mayhew ...	Napier	27⅕	132·3
4. Braun ...	Mercedes	29	124·1
5. Werner ...	,,	29⅕	123·2
6. Jenatzy ...	,,	29⅘	121·6
7. Fletcher ...	,,	29⅘	120·8
8. Warden ...	,,	30⅘	118·4

The third hill-climbing contest with standing start for the Baron de Caters Cup was held on Good Friday, on a 500-metre course on the Turbie road, commencing at the foot of the hill known as La Montée du Pin. The first contest for the cup was held on the same road, but over a kilometre course, in 1902, and was won by L. Serpollet in 59⅕ sec. Last year is was held on the Laffrey Hill (Isere), Rigolly being the victor in 50⅕ secs. This year the Gobron-Brillie cars repeated their success of the previous day, Duray securing the first position, and Rigolly the second. The times of the different competitors are as follows:—

1. Duray ...	Gobron-Brillie ...	26	secs
2. Rigolly ...	,, ...	27	,,
3. Werner ...	80-h.p. Mercedes ...	28	,,
4. Braun ...	,, ...	28⅘	,,
5. Mark Mayhew ...	Napier ...	30	,,
6. Andrew Fletcher	... 80-h.p. Mercedes ...	30⅕	,,
7. Jenatzy ...	,, ...	,,	,,
8. Warden ...	,, ...	32⅖	,,
9. De Cesti ...	... 60-h.p. Mercedes ...	36⅘	,,

It is reported that as a result of the trials certain changes are to be made in the Mercedes racers, particularly as regards the carburettors.

JOHN O' GROAT'S TO LAND'S END ON A 10-h.p. ARGYLL CAR.

LEAVING Glasgow on Tuesday, the 22nd ult., at twelve o'clock, I started to run up to John o' Groat's to try and make a non-stop run from there to Land's End and beat Mr. Stocks' record of 62 hrs. 32 mins. I arrived at John o' Groat's on Wednesday night and left the following morning at 8.15. The roads were very good, but plenty of newly-laid stones were found, which considerably delayed us. and the hills, though steep at Burrydale and The Ord, gave no trouble. All went well until 150 miles had been traversed, when a large collie dog jumping over a wall right in front of the car gave me no time to pull up and so avoid a collision. This accident so damaged the steering gear and the radiator that it rendered my companion practically unable to relieve me with the driving, thus making a non-stop run impossible.

The next stop was made soon after Blair Athol, owing to the railway gates being closed. Two other stoppages of the same description occurred, and two more for flocks of sheep, and a further stop before Glasgow owing to a blockage in the petrol pipe. The next stop was made on Shap Fells, as, owing to the radiator having been damaged by the dog, we were obliged to fill up with water. I thought it advisable to stop at Warrington and make the necessary repairs to the radiator, and we were again forced to stop at Bristol, as, in spite of our delays, we were two and a half hours ahead of our scheduled time, and, therefore, no petrol or supplies were ready. From Bristol we had a series of stoppages on account of my not knowing the road, and, it being night time, there was no one about to direct us. At Bodmin it was decided to stop the car and sleep for three and a half hours, as I had already driven for over thirty-six hours continuously. I also stopped for food, as, owing to the previous stoppages, my only object was then to break the end-to-end record.

Land's End was reached at 12.30 on Saturday, the 26th ult., the total distance of 927½ miles being covered in 52 hrs. 39 mins. as against Mr. Stocks' record of 888 miles in 62 hrs. 30. mins. The only mishaps during the run were the killing of one dog and five rabbits, and also running into a graveyard in the dark. The net running time was 44 hrs. 27 mins.

The amount of petrol consumed on the entire journey was 34⅓ gallons. The car was an ordinary 10-h.p. touring Argyll, which I had been driving for three weeks in Glasgow and through Surrey and Sussex before I had any intention of attempting this journey. The vehicle, with the exception of the steering gear, one of the front spring brackets, and the radiator, which were damaged by the dog, was in quite as good condition at the completion of my journey as the first day I drove it.

DOUGLAS H. WHITEHEAD.

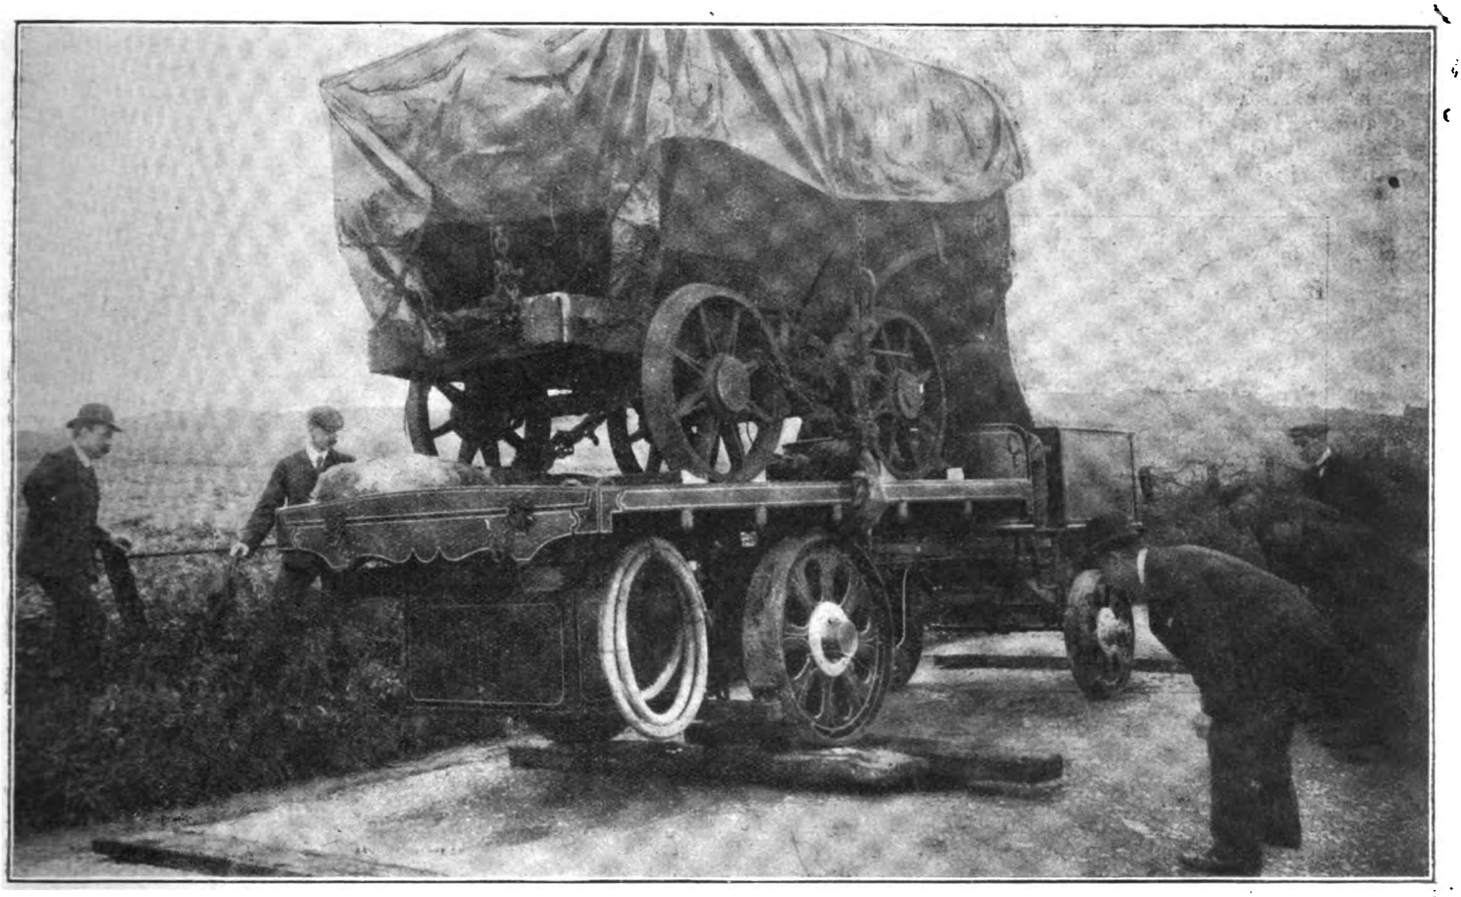
THE LONDONDERRY STEAM WAGON.



THE steam motor-wagon for conveying merchandise is enjoying increased favour in the North of England, and before long promises to become a stronger rival to the horse in the hilly north country than the traction engine has been. One of the latest forms of self-propelled heavy vehicles is the Londonderry steam-wagon built at Lord Londonderry's Seaham Harbour Engine Works, County Durham.

Originally the wagon was a by-product of Lord Londonderry's works to keep the men engaged in the intervals of constructing colliery wagons, locomotives, and repairing, the latter necessitating a large staff for emergencies. Why not make motor-wagons was a suggestion that seemed to meet the case, and the four-wheeled steam vehicle is the result.

The accompanying illustration shows one of the trials through which some of the earlier vehicles were put in order to thoroughly test their adaptability for rough and heavy work. Having satisfied a company of experts that the wagons were constructed to withstand the severest usage, hill-climbing and economy in running, as well as convenience in manipulation tests were held in Newcastle-on-Tyne and Gateshead. One of the heavy vehicles was loaded up with nitrates at the establishment of Messrs. Walter Morrison and Co., St. Peter's, Newcastle, and, after traversing some of the busiest thoroughfares in the metropolis of the North, the vehicle proceeded to climb the well-known inclines of Bottle Bank, Gateshead, and Dean Street, Newcastle. Previous to this attempt these inclines had not, we understand, been successfully negotiated by any fully loaded steam-wagon. The trials were successful in every respect, as was proved by the Londonderry Company receiving three orders from as many firms immediately after the test.

Special attention is drawn to the very substantial construction of the vehicle, no attempt being made to build vehicles for heavy work to come under the 3-ton limit, and the result is a vehicle specially suitable for general work in rough and hilly districts. Whilst the vehicle is primarily a road machine, there is an idea ultimately of fitting it so that a farmer might use it for driving corn-threshing and grinding machinery.

The engine is extremely simple in construction, and the bearings throughout are adjustable. The drive is by means of cog gearing, and the arrangement of the side frame and axle boxes is such that should a main carrying spring break, the vehicle would not be incapacitated, but could continue its journey independent of the spring. The boiler is one of the special features of the vehicle; it is of the water-tube type and built to the requirements of and passed by the Scottish Boiler Insurance Company. It is fitted with straight weldless steel tubes inclined to the horizontal, and no welded, riveted, or jointed surface is exposed to flames. Suitable doors in the end plates of the shell allow free access to the whole of the water spaces, thus rendering the boiler, on account of its convenience for cleaning, particularly suitable for districts where good water is not obtainable. All the boiler mountings are designed so that they can be overhauled when the boiler is under steam, and the driver, being able to raise or lower the ashpan with the firebars by a very simple arrangement, is able to clean out and relight the fire in a few minutes.

Testing a Londonderry Steam Wagon.

MR. JAMES BOWEN, of Didsbury and Heaton Moor, near Manchester, is erecting a garage for the accommodation of about thirty motor-vehicles. Petrol will also be stored and facilities provided for the charging of accumulators.

THE town councils of Maidstone and Bury are now to be added to the list of those anxious to obtain from the Local Government Board permission to impose the ten-mile limit upon motorists passing through their respective areas.

CONTINENTAL NOTES.

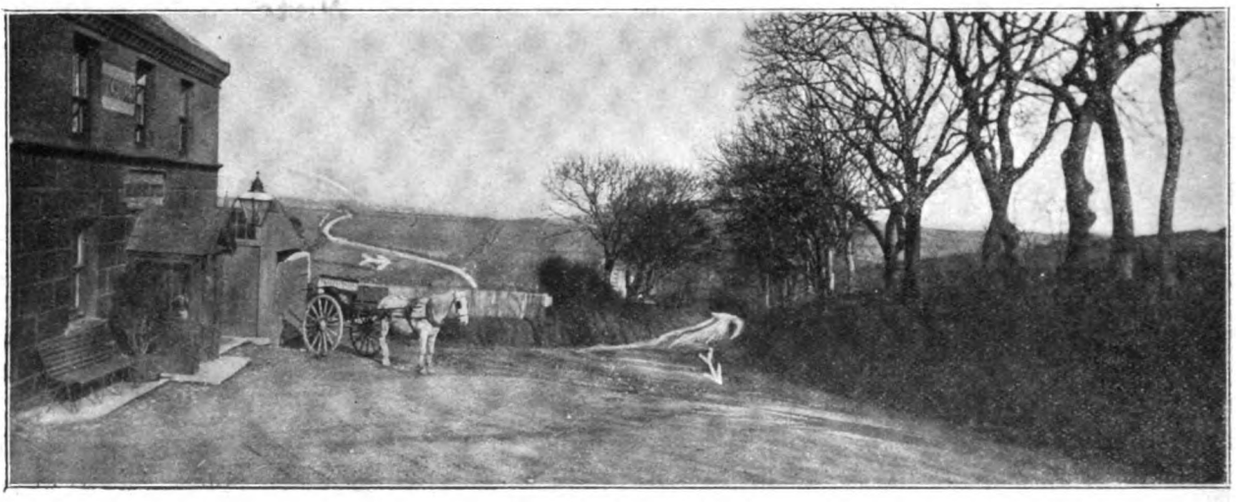
The Opel Gordon Bennett Racer.

Some further details are now available regarding the engines of the cars which are being built for the Gordon Bennett race by Messrs. Opel, of Russelsheim, Germany. As stated in the last issue of the *Journal*, the four cylinders will be cast separately. Both inlet and exhaust valves are mechanically-actuated, the inlets being located in the cylinder heads, and operated by rods and tappets. Magneto ignition is being adopted, while a carburettor of the Longuemare type will supply the mixture. The engines will each develop between 80-h.p. and 100-h.p. As for the cars, they will have [section steel frames and be built very low, the bottom edge of the flywheel being only about five inches from the ground.

Petrol Supplies during the Gordon Bennett Week.

Some anxiety is being shown as to the question of sufficient supplies of petrol in the Homburg district during the Gordon Bennett week, and there are rumours that high prices will be demanded. It is to be hoped, however, that vendors of *essence* will not follow the example of some of the hotel proprietors in charging exorbitant prices and so frighten intending visitors away. The Vereinigte Benzinfabriken Gesellschaft (Abtheilung, Benzinstationen) of Bremen has issued a list of depots around the course where supplies can be obtained. Those motorists who intend visiting Germany this summer would do well to write for a copy of the list, which can be obtained gratis.

Proposed New Automobile Regulations in France.



THE French Extra Parliamentary Commission which is enquiring into the question of the speed and regulation of automobiles in France have resumed their sittings, and are now carefully considering the reports which have been submitted for their consideration. The main points so far agreed upon are that for controlling automobiles there shall be three classes, viz.:—(1) Cars attaining a speed up to 25 miles per hour will not have to carry any number whatever, or be subject to any official declaration. (2) In the case of cars with a speed from 25 to 37½ miles per hour the existing regulations, requiring certificates of competency to drive, will be more strictly enforced than ever, and probably elaborated. (3) Vehicles capable of a speed greater than 37½ miles per hour will not be permitted to be sold or travel anywhere except under special authorisation and in very rare cases. A special plate, issued by the Service des Mines, will be attached to each *chassis* of this class, giving the gear ratio between the motor and the wheels. Any alteration in gear ratio must be immediately notified to the authorities, and a new plate obtained. With reference to the question of issuing general certificates for driving competence, it is proposed to hand this over to a private body such as the Association Générale Automobile, whose certificates would only require the endorsement of the Service des Mines

The A.C.F. Carburetto Competition.

THE rules have just been published with regard to the carburettor competition which the French Automobile Club will hold at its laboratory at Levallois-Perret, commencing on the 16th May next. The competing carburettors will all be tried on a Gillet-Forest horizontal single cylinder engine having a bore of 140 mm. by 160 mm. stroke and running normally at 850 revos. per min. The tests will have regard to (1) the power developed at different speeds and (2) the consumption in litres per kilowatt hour at different speeds. There will be three classes—(1) carburettors designed for a particular engine (2) carburettors intended for a particular fuel and (3) carburettors designed for use on any engine and to use any fuel. Entries must be sent, together with a fee of £6 per carburettor, to the A.C.F. before the 14th May.

Cups for Motor-Boat Races in Belgium.

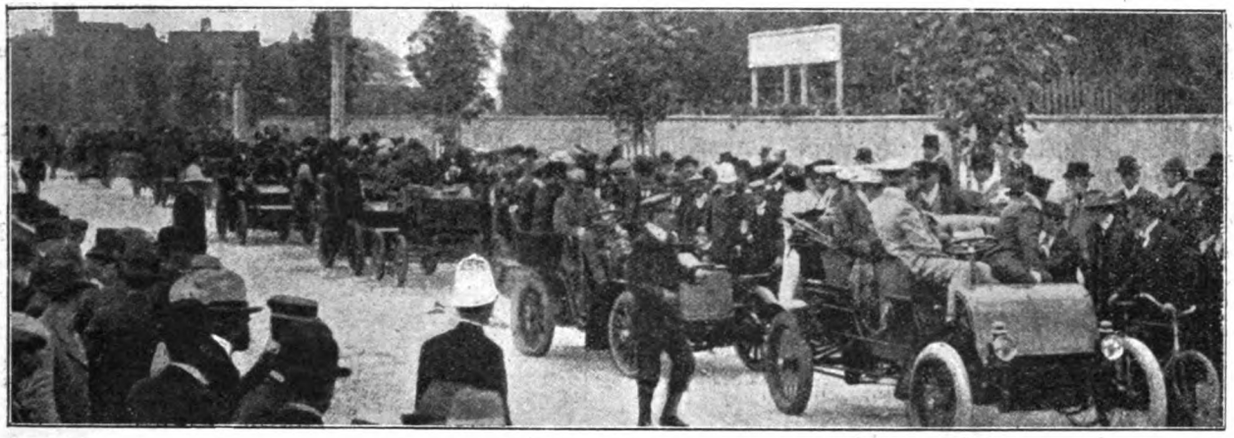
AT a meeting of the Automobile Club of Belgium, it was decided to offer a number of cups for international motor-boat races. One will be known as "la Coupe de l'Escaut," and is for an annual race on the Scheldt from Antwerp to Flushing and back, a distance of about 140 kilometres. La Coupe Littoral is for a race on the sea, starting and finishing at Ostend. There will also be La Coupe du Mille and La Coupe du Kilometre, the details of which have yet to be settled.

[*Photo by* The British Gordon Bennett Eliminating Race in the Isle of Man. View of the Course at Richmond Hill. [*D. Collister, Douglas.*

Exhibition at Nice.

AN exhibition of motor-cars was opened on Sunday in a large temporary show-ground behind the Casino at Nice. Among the cars on view are Mercedes, Peugeot, Panhard-Levassor, De Dion, Gardner-Serpollet, Renault, Fiat, Berliet, and Aries. A notable feature of the exhibition is a huge aeroplane flying machine driven by a 6-h.p. motor.

Austrian News.



PREPARATIONS are well in hand for the Austrian Automobile Club Show, which is to be held in Vienna from the 16th inst. to the 31st May. On the 5th May there is to be a trial of passenger cars the motors of which use alcohol or petrol as fuel, while on the 10th May there will be a heavy-vehicle competition.

Motor-Boats at Monte Carlo.

A MOTOR-BOAT exhibition was opened on Wednesday last week at Monte Carlo by the Prince of Monaco. It is a novel and interesting show, there being over sixty exhibits, including the Napier Minor," shown by Messrs. S. F. Edge and Company.

The First Run of an Australian Club.

The Start of the Run.

CONSIDERABLE interest was taken by the Melbourne public in the inaugural run of the Automobile Club of Victoria, news of which reached us by the last mail. Prince's Bridge, Melbourne, was the point of assembly, the destination being Aspendale Park, eighteen miles away. The weather, although threatening in the morning, cleared up about noon, the afternoon being in every way favourable for motoring. Large crowds watched the start, while numbers of spectators lined the route through St. Kilda, East Brighton, Cheltenham, and Mordialloc. A considerable number of the local residents visited the park to watch the evolutions of the cars and motor-cycles.

At a quarter-past two the motor-cycle detachment, twenty strong, under the direction of Messrs. H. C. Bagot and E. C. Joshua, made a start, proceeding in a body to the St. Kilda Town-hall, after which they rode in detachments, arriving at the park about half-past 3 o'clock. As the motor-cars arrived at the starting-point they were ranged along the left-hand avenue of St. Kilda Road, and made an imposing array as they were marshalled in a line about a quarter of a mile long, the club's vice-president (Dr. A. P. Merrill) having the position of honour. Almost every conceivable type of motor-car was represented in the 30 odd vehicles present, ranging from a 16-h.p. 4-cylinder tonneau down to a little American Buckboard runabout, whilst numerous steam cars were also in evidence. The value of the cars at the meet was estimated at over £9,000.

Aboard the cars were to be seen Sir Samuel Gillott, Alderman J. Moloney, Councillors C. Pleasance and C. E. Jeffries, the city surveyor (Mr. A. C. Mountain), the mayor of St. Kilda (Councillor J. H. Pittard), and several councillors of the town of Brighton. At half-past two the cars got under way, Dr. Merrill, with Sir Samuel Gillott aboard, being in the van. A ten-mile-an-hour pace was set along St. Kilda Road and around the Esplanade, thence to the St. Kilda Town-hall, where a short stop was made to pick up several passengers. From here the cars proceeded in more open order, to escape the dust. Maintaining a nice easy pace, Aspendale Park was reached about 3.45 p.m.

After refreshments at the chalet, an adjournment was made to the race track, which was placed at the club's disposal by Mr. J. R. Crooke, who is himself a motorist. Several motor-cars and motor-cycles had a run around the racecourse, but the going was too heavy to enable any speed work, so the remainder of the afternoon was devoted to driving visitors around the grass track. During the afternoon the opportunity was taken by the vice-president (Dr. A. P. Merrill) to thank the visitors for their attendance, particularly those who had journeyed down in the cars. He trusted that the experience gained by them, showing the facility and ease with which automobiles can be handled at all speeds, and the perfect manner in which they can be controlled would be of some assistance to the various municipalities when framing the new by-laws regulating motor traffic.

An early return citywards was made by most of the motorists, the afternoon's outing being a most enjoyable one, and in every way worthy of the newly-formed club, which promises to have a great future. The arrangements of the run were placed in the hands of Messrs. H. J. J. Maddox, H. C. Bagot, S. H. Day, W. Rose, and H. B. James (hon. secretary). Amongst those noted at the meet were Dr. A. P. Merrill (Winton, 8-h.p.), Messrs. S. Stott (Decauville, 16-h.p.), J. R. Crooke (Locomobile, 4-h.p.), W. S. Ross (Argyll, 10-h.p.), H. Tarrant (Argyll, 10-h.p.), J. Moffat (De Dion, 8-h.p.), H. H. Witt (Locomobile, 4-h.p.), C. B Kellow (De Dion, 8 h.p.), S. Darby (Toledo, 8-h.p.), R Moffat (De Dion, 6-h.p.), Dr. Grimwade (Humberette, 5-h.p.), H. R. Grimwade (Humberette, 5-h.p.), N. Grimwade(De Dion, 6-h.p.), Dr. Officer (Oldsmobile, 4-h.p.), W. Hurst (Eclaire, 5-h.p.), J. Beswicke (Locomobile, 4-h.p.), J. Prince (Winton, 8-h.p.), E. C. Winn (Oldsmobile, 4-h.p.), F. Stuart (Decauville, 10-h.p.), C. Waddington (Oldsmobile), 4-h.p.Otto Schumaker (De Dion, 3½-h.p.), W. J. Warden (Oldsmobile, 4-h.p.), C. Hall (Oldsmobile, 4-h.p.), H. Thomson (Thomson, 8-h.p.), Boehmke (Oldsmobile, 4-h.p.), A. Renard (Rochet, 5-h.p.), H. L. Stevens (Knowles-Aster 5-h.p), J. Neave (Oldsmobile, 4-h.p.), F. Bennett (Toledo, 6-h.p.), F. M'Ganis (Oldsmobile, 4-h.p.), W. Guild (De Dion, 6-h.p.), Stott, jun. (Covert, 5-h.p.), H. J. J. Maddox (Knowles-Aster, 5-h.p.), C. A. Proctor (Orient Buckboard, 3½-h.p.), D. Mackenzie (Oldsmobile, 4-h.p.), A. Kennedy (Oldsmobile, 4-h.p.).

AT a meeting of the Civil and Mechanical Engineers Society on Thursday, Mr. Holroyd Smith read a paper on "Friction Clutches and their Application to Motor Cars."

WE regret to learn of the sudden death, at Ramsgate, on the 3rd inst., of Mr. E. M. Bowden, the inventor of the Bowden patent wire mechanism and the Bowden brake. In the early winter Mr. Bowden contracted a severe cold followed by influenza, and he was unable to shake off the effects of that indisposition. Latterly his trouble took a more serious turn, pneumonic symptoms developing.

STANLEY SHEPSTONE, a motor-car driver employed by a motor car company in Peland Street, W., was going along Maida Vale, the other afternoon, when a van in front of the car suddenly turned half round. In trying to avoid a collision the car was turned completely over, and Shepstone was pinned underneath, where he remained for several minutes before he could be released. He was conveyed to St. Mary's Hospital.

MOTOR-CYCLING NEWS.

THE 1904 motor-cycle racing season opened on Good Friday by a five-mile handicap on the track at Canning Town, E. The conditions under which the event was run included a provision that the engine dimensions were not to exceed 76 mm. bore by 76 mm. stroke or their equivalent. In the first heat J. F. Crundall (Humber), H. V. Collier (Matchless), H. J. Butler (Koh-i-Nor), and C. S. Prentice (Prentice) ran, the first-named winning in 7 min. 32 3-5 sec. Heat two brought out B. Yates (Humber), C. R. Collier (Matchless), C. Bennet (Kerry), and W. W. Genn (Eland). The heat was won by Collier in 7 min. 53 3 5 secs. In heat 3 the competitors were H. A. Collier (Matchless), J. Perkins (Crownfield), H. J. Trow (Trow), and F. E. Barker (Dart), Collier winning in 8 mins. 14 1-5 secs. The first two in each heat competed in the final, which was won by Crundall in 7 mins. 32 4-5 secs., C. R. Collier being second, and H. A. Collier third.

A SIMILAR handicap was run off on the same track on Monday last, Crundall repeating his victory of the previous Friday in 6 mins. 56 1-5 secs.

MOTOR-CYCLE belts in raw hide or chrome leather are made by Messrs. Fleming, Birkby, and Goodall, Limited, in standard, medium, and heavy sections. "Teon" motor-cycle belts also find illustration in their new catalogue.

Motor-Cycles for Military Purposes. A Signalling Corps at Work in the German Manœuvres.

[Automobil Welt.

AN Algerian motor-cyclist named Constant has just made a new record between Algiers and Setif. The distance is about 210 miles, and this he covered on a 2½-h.p. Griffon machine in 8¾ hours, a very good performance on Algerian roads.

ON Good Friday the motor-cycle section of the Sheffield Automobile Club had a run to Bakewell, and on Monday went to Retford via Worksop. Their programme for April includes runs every Thursday and Saturday, and the places visited will be Baslow, Worksop, Askern, Bambury, and Castleton.

AMONG the new motor-cycles to be put on the market during the coming season is the "Fuller." The motor is located in a vertical position in a loop frame with duplex front forks and will be of 2, 2¾, or 3½-h.p. Longuemare carburettor, Bowden valve lifter, Fuller trembler coil and dry battery or accumulator, belt drive, and Bowden rim brake are other features of this machine, which is being introduced by the firm so long associated with battery work.

To mitigate the evil of straggling on club runs the Chicago Motor-cycle Club has hit on the idea of establishing stations or "controls" at the cycle depots in and around Chicago, at which stops will be enforced until the laggards catch up. These places of rendezvous, it is thought, will make it possible for the club to complete its runs in a body.

AUTOMATIC CARBURETTORS.

IN the early history of the motor-car a carburettor was deemed sufficiently perfect if it was capable of furnishing a mixture of fairly reliable inflammability through the range of gas consumption demanded in usual practice. Very little pains were taken to insure absolute uniformity of the mixture at different speeds and rates of throttle openings, the main consideration being to secure a mixture which ranged in its composition between the limits of inflammability, and thus would not fail to ignite. Carburettors were originally of most diverse forms, including those of the surface type and vaporisers employing needle valves actuated by the inlet valve movement. These and other forms have virtually passed away, leaving the carburettor of the float feed spraying type pre-eminent, if not practically standard in the industry. The float feed carburettor has been universally adopted on account of its small size and compact form and its virtual independence of atmospheric conditions. Its output of gas in respect to its size and weight is quite remarkable.

The ability of the float feed carburettor to deliver a combustible mixture to the motor, through a very wide range of gas demand, has satisfied everyone as to its thorough practicability; but now that all parts of motor-cars are being subjected to criticism more intense than ever before it is being realised that the float feed spraying principle, unless carried out with the utmost refinement, does not result in the production of a uniform quality of gas under all conditions of demand. Since there is very little variation allowable in the gas quality without a decided loss in output and efficiency, improvements in carburettor construction are, remarks the "Horseless Age," highly desirable, and it is very noticeable that manufacturers are adding auxiliary devices to their carburettors for the purpose of automatically maintaining the proportions of air and petrol under all conditions. A valve actuated by the inflow of air and arranged to govern the degree of contraction to which the entering air is subjected may be utilised as an auxiliary mechanism, or an auxiliary air passage may be opened or closed by means of a diaphragm. Whatever method may becomd the final one, it is evident that this subject of uniformity oe mixture is attracting serious attention at the hands of autof mobile designers.

THE Ladies' Automobile Club is about to remove to its new headquarters at Claridge's Hotel, W.

MR. RICHARD PAULSON, of Hove, is bringing out a new speed indicator for ascertaining the speed of motor-cars.

DON'T quarrel with your motor-car. If it doesn't act to please you, remember that it is a mere machine and that you are a man and its master. But to command it you must first know its peculiarities.

PROVIDENCE, Rhode Island, U.S.A., is to have an automobile school, the Young Men's Christian Association of that city having decided to organise a course of lectures treating of the operation, care and construction of motor-vehicles.

WE learn that the Locomobile Company of Great Britain, Limited, of which Mr. C. Jarrott and Mr. W. M. Letts are now directors, has secured the sole and exclusive agency for Great Britain and Ireland (except Yorkshire) for the "Spyker" cars, which have recently been described in these columns. Certain modifications are being made in the design of the cars which will not only improve their appearance, but also enhance their efficiency. The chief of these is the shape of the front spring hangers, which has now been altered in such a way that there is no straight cross pin at the front end of the springs as formerly, the springs being placed solidly under the front end of the spring hangers. The cars, which are of Dutch manufacture, are made in three sizes, namely, 14-h.p., 20-h.p., and 25-h.p. The Elsworth Automobile Company, of Bradford, will continue to act as the Yorkshire agents for "Spyker" cars.

HERE AND THERE.

LORD FARQUHAR has, we learn, just placed an order for a six-cylinder "Napier" car.

MESSRS. THOMPSON AND COMPANY have lately extended their motor-car works at Frome.

SIR ALFRED HICKMAN, BART., M.P., has, we understand, placed an order for a 28-36-h.p. car.

SOME of the residents of Eastbourne are endeavouring to raise a petition to the local Council in favour of more encouragement being given to tramways as opposed to motor-cars in the future.

THE Gas Lighting Improvement Company, Limited, have recently started their new refinery at Pacific Wharf, Crows' Road, West Ham, where they deal specially with the preparation of motor spirit.

THE Public Health Committee of the Wandsworth Borough Council has been authorized to procure a motor-van, at an estimated cost of £360, for the removal of infected articles to the disinfecting station.

THE Automobile Company of Cardiff, Limited, has been registered with a capital of £2,000. The first directors are Messrs. G. L. Watson and A. S. Little, and the registered office is at 20, Charles-street, Cardiff.

THE new booklet on the Werner motor-cycle which has just been issued will well repay perusal. It not only deals with the particular merits of the Werner machines but is full of illustrated matter of interest to motor-cyclists generally.

DETROIT has joined the list of American cities which have established "automobile schools," or courses of instruction in motor vehicle construction and management. The local Young Men's Christian Association is the moving spirit in the scheme.

THE Putney Motor Company, Limited, has been registered with a capital of £5,000 to acquire the business now carried on at 17, Grand Parade, Putney, S.W., as the Putney Motor Company. The first directors are Messrs. A. E. S. Craig, G. L. M. Dorwald and E. A. D. Kisch.

SIR GEORGE NEWNES, M.P., in presiding at the meeting of the Lynton and Barnstaple Railway, complained that the unnecessary restrictions of the local authorities had put a stop to a valuable motor-car service in connection with the railway between Ilfracombe and the surrounding district.

THE Putney Motor Company are building a specially powerful four-cylinder car for the Earl of Norbury. Owing to the great flexibility of the motor only one low gear will be fitted for use in starting and on steep hills; at other times the transmission will be direct by worm drive to live axle. The front road wheels will be 36 inches in diameter; the rear pair, which will be fitted with solid tyres of very large section, will be 48 in. diameter.

FROM the Homeland Association comes another of their excellent series of handbooks to pleasant places in the southern counties. This is number 30 of the series, and is concerned with Littlehampton, Arundel, and Amberley. While not pretending to be a complete guide to the antiquities and modern developments of the places named, it has the merit of giving in a concise form all that the tourist needs to know concerning those interesting localities.

THE Noble Motor Company has lately brought out a combined dynamo and motor for charging accumulators or for lighting small country houses. The set is comprised of dynamo and engine, which can be run with either petrol, paraffin, or gas, and an extra heavy fly-wheel to ensure steady running. These are mounted on a cast iron base forming the water tank; a centrifugal pump is also attached to circulate the water through the engine water jacket. The engine is governed, to prevent racing when the load is taken off the dynamo, by a special electrical contrivance.

A SECTION of the Swiss Automobile Club has just been formed at Zurich.

A NEW service of motor-'buses at Falmouth was announced to start running on Easter Monday.

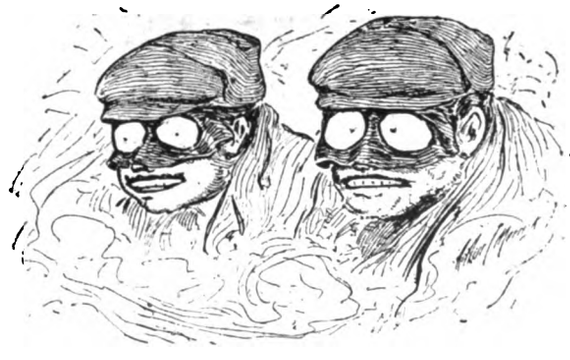
THE Maudslay Motor Company are, we hear, bringing out a new car fitted with a two-cylinder engine.

A LECTURE entitled "Popular Motor-cars" will be given before the Society of Arts on Wednesday, the 20th inst., by Mr. Mervyn O'Gorman.

MESSRS. LAKE AND ELLIOTT, of Braintree, have sent us a copy of their new catalogue, which contains illustrations and particulars of a variety of apparatus and tools which will be found useful by motor-cycle and car repairers.

WE hear that there is an enquiry in the market for a motor vehicle or wagons for military purposes to carry a load of 25 tons a distance of about 60 miles without a stop. The wagon is to be propelled by other than steam power.

TWO additional classes were added at the last moment to the contest of commercial automobiles which is being held this week by the Automobile Club of America. The new classes are for heavy trucks, carrying respectively 6,000 to 8,000 pounds and upward.



THE British Motor Power Co., of Preston, have just issued in pamphlet form the paper read by Mr. O. Sumner, M.I.M.E., before the Institute of Marine Engineers recently on "Marine Petrol Engines and Motor Launches." Particulars are also given of the "British Marine" paraffin and petrol engines and launches.

A TECHNOLOGICAL and Scientific Dictionary is the latest enterprise of Messrs. George Newnes, Limited. This is being issued in fifteen monthly parts, and when complete will define about 16,000 terms, 6,000 of which are in various branches of engineering. The first part, just issued, is well printed and the illustrations are practical and useful.

WE are informed that the Continental Caoutchouc and Guttapercha Company have taken new premises in Clerkenwell Road, E.C., which will be occupied in a few months' time. The offices and warehouse are much larger than those at present occupied by the concern at Holborn Viaduct, and will enable the concern to put down plant for the repair of tyres.

MESSRS. DOCKER BROS. are specialising on paints for motor-cars, these being prepared to withstand heat as well as to give a high polish to the work. Regal red is one of their excellent lines, and at the recent Show at the Agricultural Hall a display of panels gave an opportunity for visitors to judge of the excellent results that can be obtained from the use of their paints and varnishes.

AT the Denbigh Police Court, Colonel T. A. Wynne Edwards, a county and borough magistrate, was fined 1s. and costs for not having a licence for the driver of his motor wagon. The defendant, whose excuse was his forgetfulness, said that this conviction would mean a loss to the county of Denbigh. He would take out a licence in the county of Flint, which would answer the same purpose, and he would never take out another in Denbighshire.

The Motor-Car Exhibition at the Agricultural Hall.

[THIRD NOTICE.]

[*Photo by* The Heavy Motor Vehicle Section in the Minor Hall. *Argent Archer*,

CONTINUING our review of the stands at the Motor Car Exhibition, we would emphasise one point of the display to which several of our contemporaries have already borne witness, viz., the excellence of the staging of exhibits and the way in which firms endeavoured to give an artistic touch to the whole display. The scheme of decoration arranged by the promoter of the Show harmonised well with the displays made by exhibiting firms, and something of the gracefulness which characterised the Paris Salon was apparent at the Agricultural Hall.

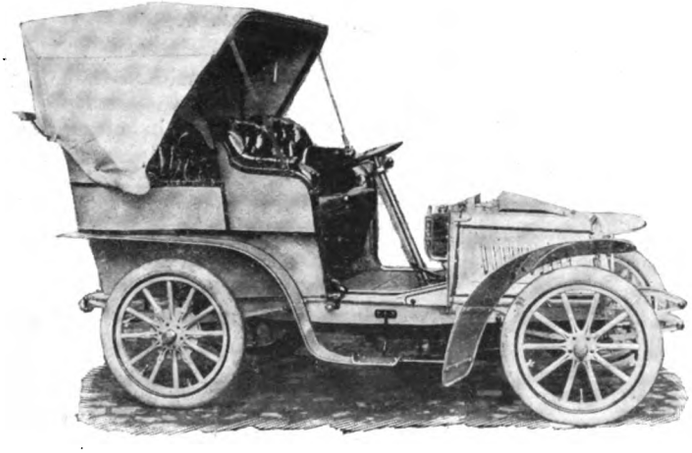

Fig. 67.—The Darracq 12-h.p. Car.

PETROL CARS.

An excellent display of Darracq cars was made by MESSRS. A. DARRACQ AND CO., ranging from 8-h.p. to 28–32-h.p. The 15-h.p. car is the most recent introduction; it has a pressed steel frame of new design, slightly narrowed at the fore part to allow the car to turn in a much smaller circle than previously. The four-cylinder engine has mechanically-actuated inlet valves, accumulator ignition, governor acting on the inlet, honeycomb radiator and fan, and all other modern fitments. The cardan shaft and bevel gear system of transmission is still retained, while the gear box is adapted to give three speeds ahead and one reverse, with direct drive on the top speed. The lubrication is effected by pressure from the exhaust, while, in order that there shall be no failure in the supply of petrol to the carburettor when travelling over hilly roads, an auxiliary petrol tank is fitted under the bonnet. The brakes on the car are of the internal expanding type, and, of course, act equally well whether the car be running in a forward or backward direction. Fig. 67 depicts the Darracq 12-h.p. two-cylinder car with hood. The Darracq Company are devoting much attention to the demand for cars, the rear seats of which can be reached from the pavement, and are building vehicles of this type in the 12-h.p., 15-h.p., and 24-h.p. models.

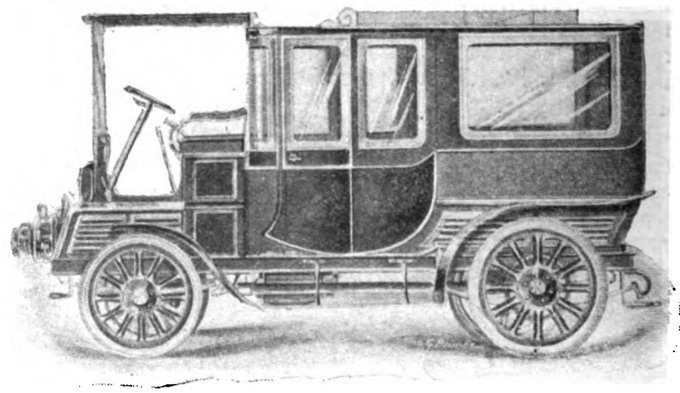

Fig. 68.—The Brillie 20-h.p. Coupe-Omnibus.

Two examples of an interesting new type of vehicle were seen for the first time in England on the stand of the MOTOR CAR EMPORIUM, LIMITED, they being built to the designs of M. Eugene Brillié by Messrs. Schneider

Digitized by Google

and Co., the great French gun-building concern. Fig. 68 shows the 20-h.p. coupé omnibus, the body, which is divided into two compartments, having accommodation for ten inside passengers. The channel steel frame is carried on very long semi-elliptic side-springs, those at the back having shackles at the rear end, and curiously-shaped flexible connections at their front ends. The engine, which is located under the front seat, comprises four cylinders, with mechanically-operated inlet valves above the exhaust valves. The cylinders are cast in two pairs; special provision has been made for lubrication of the various parts, while the bottom half of the crank case can be removed without disturbing the bearings, so giving access to the crank shaft and connecting rods. The governor is adapted to act on the admission; an automatic carburettor, having a spring-loaded auxiliary air valve, is used; this is provided with a jacket through which the exhaust gases may be circulated, rendering it suitable, it is claimed, for utilising paraffin as fuel as well as petrol. From the engine the power is transmitted through an internal cone clutch to a gear box, giving three speeds forward and a reverse, with direct drive on top speed. From the gear box a propeller shaft conveys the power to a differential shaft above the back axle. The ends of the differential shaft carry spur wheels, which mesh with internal gear rings, bolted to the rear road wheels. Eccentric bearings are provided to the differential shaft to permit different-sized spur wheels being fitted to it, and thus to permit the vehicle being geared higher or lower according to requirements. The brakes, which act upon the drums fixed to the back wheels, are constructed of steel cable, while the foot brake, at the rear of the gear box, is of the metal-to-metal type. Fig. 69 shows the Brillié petrol lorry designed to carry a load of 2½ tons at speeds up to eight miles per hour. This is a very substantially-designed vehicle; except that the motive power is supplied by a two-cylinder engine developing 10 to 12 h.p., the general arrangement of the mechanism is similar to that of the coupé-omnibus described above. The Motor Car Emporium, Limited, also exhibited a Durkopp 15–16-h.p. three-cylinder tonneau and a two-seated car of similar power. This is a chain-driven vehicle, which has already been described in the *Journal*. Considerable interest was shown in the "Nonex" device for rendering petrol tanks and cans explosion proof. It is claimed that by means of the "Nonex" arrangement a light can be placed close to the mouth of the tank without any danger of fire or explosion.

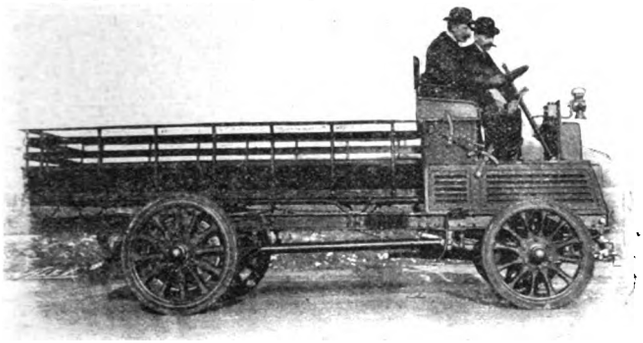

Fig. 69.—The Brillie 2½-h.p. Petrol Lorry.

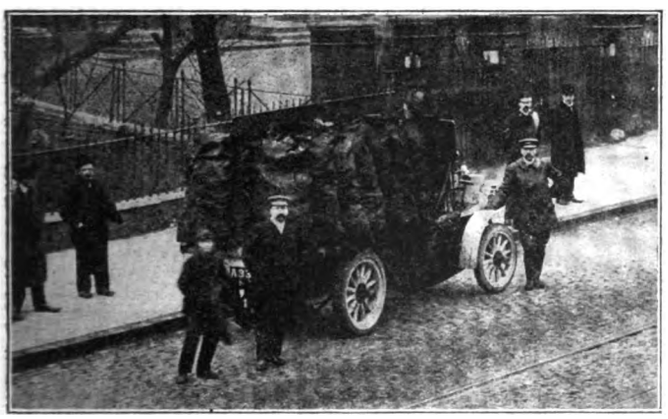

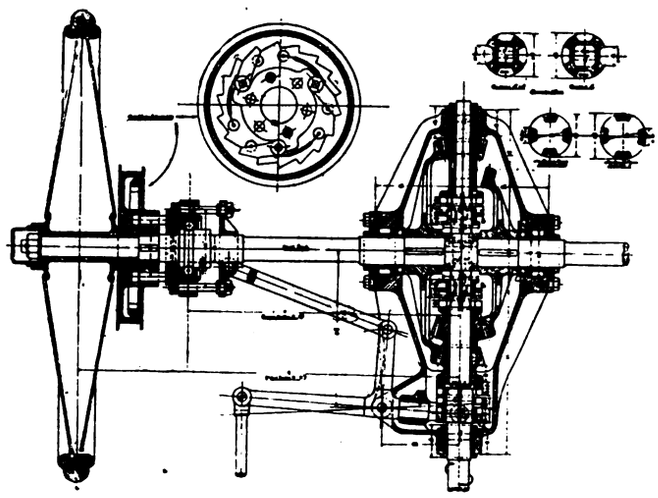

Fig. 70.—The Orion Petrol Lorry with a Load of 3 ton of Coal.

A petrol lorry for commercial purposes, new to this country, was exhibited by the "Orion" Motor Lorries and Omnibuses. It is of Swiss construction, and attracted much attention by reason of the fact that it was driven into the Show with a full load of coal in sacks. The vehicle is made in a variety of sizes, the particular one under notice being of three-ton capacity. The motive power is supplied by a 12-h.p. single-cylinder horizontal engine, located in the fore part of a channel steel frame and running at a normal speed of from 650 to 700 revolutions per minute. Ignition is by means of magneto, and the water circulation by pump and fan-cooled radiator. Four speeds forward and reverse are provided, the power of the engine being transmitted by a Renold silent chain to the gear box, and thence by side chains to the rear road wheels, which are shod with 6 in. solid rubber tyres. During the fortnight prior to the Exhibition, the vehicle had been employed in carrying coal for Messrs. Cameron, at Shepherd's Bush, Kensington, Woolwich, Tulse Hill, Brockley, and St. Pancras. In ten days 104 tons of coal were carried in 2 to 2½-ton loads on a consumption of forty-seven gallons of petrol, Messrs. Cameron reporting that the lorry had successfully accomplished all the tests they could submit it to in sending it up the steepest hills round about their various depots in London. Fig. 70 depicts the lorry in Pentonville Road, King's Cross, on its way to the Show.

Considerable interest was shown in the new 6-h.p. "Horbick Minor" car, seen in London for the first time on the stand of Messrs. Horsfall and Bickham, and of which an illustrated description was given in the *Journal* of the 30th January last. The motive power is supplied by a 6-h.p. vertical motor, set in the fore part of a tubular steel frame. The cylinder is 94 mm. diameter by 94 mm. diameter, the valves being interchangeable with those of the 6-h.p. De Dion. The usual high-tension system of ignition, with wipe contact maker, is fitted. The water circulation for the cooling of the engine is maintained by means of pump and radiator. One of the special features of the car is the combination with the engine of a reducing gear, which transmits power through a secondary shaft at 700 revolutions per minute, or thereabouts, according to the sizes of the wheels used. From the motor clutch to the rear axle the power is transmitted by means of a rigid shaft with a flexible coupling at the clutch end only. The change speed gear is combined with the transmission to the rear axle, two speeds and reverse being provided. The gear, shown in section in Fig. 71, is always in mesh, and is on the skew bevel principle. It is claimed to be more silent than the ordinary bevel gear, and obviates the necessity for breaking the shaft and rear axle where they cross each other, and where the strength is required. The engine is controlled by the throttle and ignition levers; and by means of these, together with the change gear, any speed from four to twenty-five miles per hour can be obtained. The wheel base of the vehicle is 5 ft. 4 in. and the overall width 4 ft. 2 in.; the approximate weight of the car is 7 cwt. Steering is controlled by an inclined wheel, while the foot and hand brakes are of the double-acting metal to metal type. Ball bearings are fitted to both the front and rear axles; the road wheels are 28 in. in diameter, shod with 2½-in. pneumatics. The car is neatly upholstered and painted, and has ample room for the fitting of a third seat or a touring or a travellers' basket

71.—Change Speed and Transmission Gear of "Horbick Minor" 6-h.p. Car.

The exhibit also comprised a *chassis* and complete 10–12-h.p. Horbick car. The main frame is of tubular construction, an under-frame of planed channel steel being provided to support the motor and gear box. In the fore part of this is carried a two-cylinder motor, the dimensions of the cylinders being 4 3-16 in. diameter by 4¾ in. stroke, the normal speed being 800 revolutions per minute. The inlet valves, which are mechanically operated, are located on the top of the cylinders. An automatic governor acting upon the throttle valve is fitted, while the normal speed of the engine can be varied by a lever on the steering pillar. Three forward speeds and a reverse are provided, the power being transmitted direct on the top speed by a cardan shaft and bevel gearing to the rear live axle. The change speed gear is of the sliding type, the side shaft being noticeable in that it, together with its spur wheels, is machined out of a solid bar. A spring drive is interposed between the engine and gear box. The rearward end of the clutch shaft is provided with a flange upon which are mounted by their centres two springs which embrace between their two free ends a flat driver on the primary gear shaft. The drive is thus conveyed to the gear through the ends of these springs, which, it is claimed, allow sufficient give to save the gear from all injurious shock. A telescopic coupling is introduced in the cardan shaft conveying the power from the gear-box to

Digitized by Google

the rear axle. The foot and hand brakes are of the metal-to-metal expanding type. A new Horbick car for the 1904 season is one of 14 h.p.; in general arrangement it follows the lines of the 10–12-h.p. cars; it is, however, fitted with a four-cylinder engine, 90 mm. bore by 100 mm. stroke, all the valves being mechanically-operated off one cam shaft.

One of the most interesting petrol vehicles in the Minor Hall was the 3-ton petrol lorry exhibited by the EMPIRE HAGEN MOTOR WAGON COMPANY, of Sheffield. The feature of the vehicle is found in the transmission gear, any desired speed between zero and maximum being obtained by means of eccentric driving and clutch mechanism. Since the vehicle was illustrated and described in the *Journal* of October 17th last a number of improvements have been effected. The 16–20-h.p. four-cylinder vertical motor has mechanically-operated inlet valves, and is placed in front of the wagon under a bonnet. The engine, which normally runs at 900 revolutions per minute, can be varied by means of a throttle from 250 to 1,200 revolutions. Passing to the variable transmission, this comprises a crank, the stroke of which is changeable automatically through the motor, by moving a small lever on the steering pillar. The crank pin is connected by a connecting rod with a rocking arm. The latter is connected by two rods with the levers of the clutch mechanism, and, the stroke of the crank being changeable, any desired speed is obtained without the slightest jerk. The gear has recently been improved, in that the double adjustable crank is connected directly with the oscillating levers of the clutch mechanism, without having the rocking arm and the intermediate axle. The clutch mechanism fitted on the hind axle consists chiefly of a hardened steel disc, which has one circular slot on each side. In each slot are seven projecting members of specially-formed cramps. The pointed ends of the latter fit in two oscillating levers in such a manner that if the levers are in motion through the stroke of the adjustable crank with which they are connected by rods, only the "noses" of the pulled lever catch the cramps and cause them to immediately grip the disc in the slot, pulling the disc round in one direction, and thus obtaining a constant motion forward. The whole mechanism runs in oil and is covered by a dust-proof case. The wagon is furnished with two powerful brakes—one operated by the foot and a double block brake applied by hand.

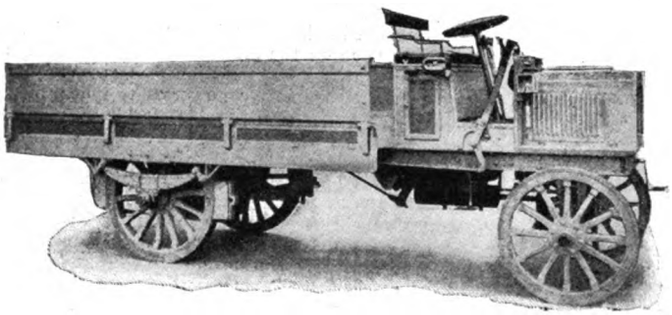

Fig. 72.—The Empire Hagen Petrol Wagon.

So much has been spoken at various times of a little car which shall not cost more than a hundred pounds, that it was not unnatural that the "Bijou," which has been introduced to meet this want, should come in for a large amount of attention. The vehicle, of which an illustration is given in Fig. 73, is made by the PROTECTOR LAMP AND LIGHTING COMPANY, which exhibited a number of them, varying only as regards the body work. In the fore part of a steel frame is set a 5-h.p. horizontal engine, having a cylinder 3¼ in. diameter by 4 in. stroke, the speed being variable between 200 and 1,400 revolutions per minute. The usual high-tension ignition is fitted, while the water circulation is on the thermo-syphon system, no pump being employed. The water is carried in a specially-shaped brass tank, in which are inserted a number of tubes forming air passages, which serve to keep the water cool; the tank itself is placed above the engine, of which it practically forms the bonnet. The hot water on its return to the tank passes around the carburettor, to which it imparts some of its heat. The crank shaft is connected to the countershaft by two chain drives of different ratios, the sprocket wheels each having metal-to-metal clutches in conjunction with them, so that the power may be transmitted through either of the chains, two speeds forward being thus provided. No reverse motion is fitted, the car complete weighing under 5 cwt. From the countershaft the power is conveyed to the rear axle by a single central chain to the rear live axle. No differential is fitted, the rear wheels being provided with free wheels, and are thus able to over-run each other in turning corners. Provision is made for adjusting the chains, and the engine can be started from the seat by means of a spring arrangement. Steering is controlled by a small handle or wheel as desired; two brakes are provided, while the road wheels are of the cycle type, shod with 2¼ in. pneumatics. Fig. 73 shows the standard car; it can also be supplied with hood and foot glass screen, rendering it suitable for doctors' use, or with a van body. Any speed up to twenty miles per hour can be attained.

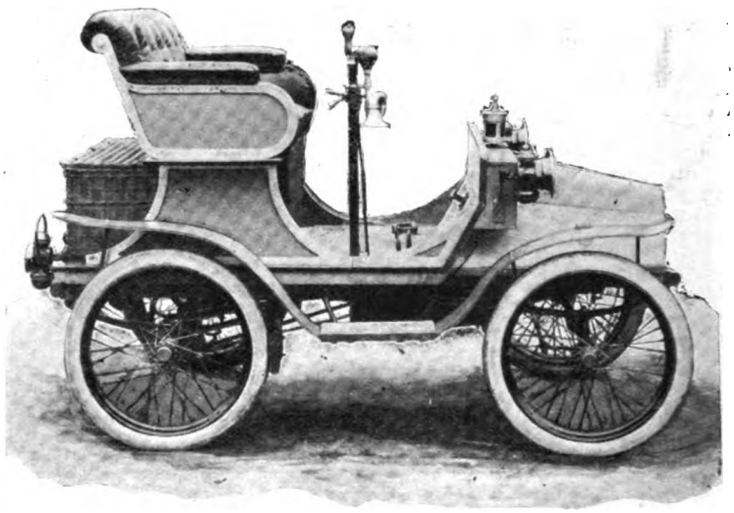

Fig. 73.—The 5-h.p. "Bijou" Car.

The stand of MESSRS. J. W. BROOKE AND CO., LIMITED, attracted considerable attention, not only on account of its novel design, but chiefly because of the new 15-20-h.p. Brooke car, which made its first public appear-

Fig. 74.—The "Brooke" 12-14-h.p. Three-Cylinder Car.

Digitized by Google

ance at the Show. As we propose to deal with the new vehicle at length in an early issue, we will content ourselves on the present occasion by stating that it comprises a number of special features, particularly in the transmission, which created an excellent impression. Messrs. Brooke also exhibited one of their three-cylinder light cars (Fig. 74) fitted with tonneau body painted all red with green leather upholstery. The engine comprises three cylinders giving 12–14-h.p., with mechanical valves, both inlets and

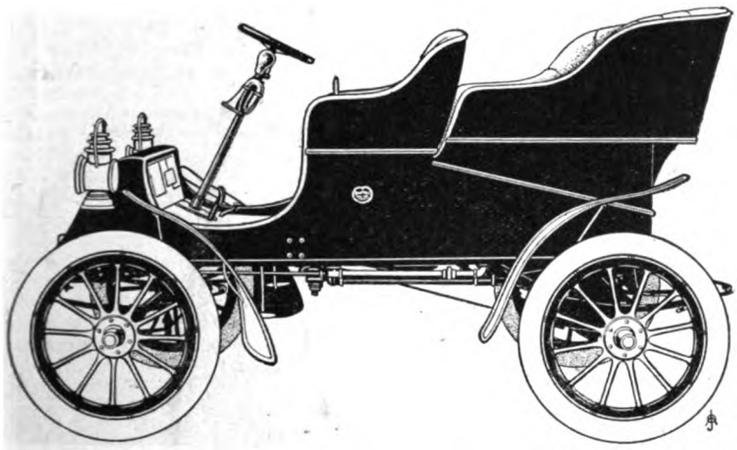

Fig. 75.—The "Ford" 8-h.p Tonnear.

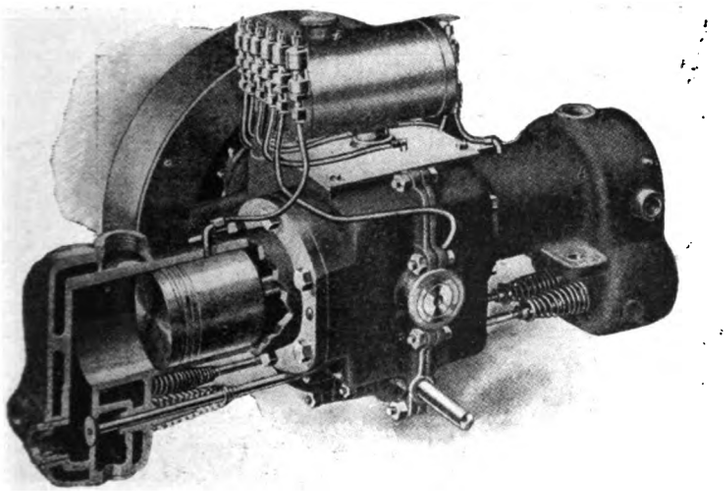
exhausts being actuated from one cam shaft. High tension ignition is fitted and a Panhard type of gear change with through drive on top speed. The cooling is by honeycomb radiator and fan and the frame is of pressed steel. A 12–14-h.p. standard Brooke car was also shown, this being fitted with tonneau body painted blue with red upholstery. In this car the regular "Brooke" practice has been followed, in which the engine is placed transversely on the frame, the drive being by means of Renold silent chain to the gear box, three speeds forward and one reverse controlled by one lever being provided.

The novelty on the stand of the AMERICAN MOTOR-CAR AGENCY was a 8-h.p. Ford car (Fig. 75), a vehicle of American construction, which has hitherto not been seen in England. The motor is of 8-h.p., and is of the double-cylinder horizontal opposed type and centrally placed in the frame in order to distribute the weight equally upon the two axles. The cylinders are 4 in. diameter by 4 in. stroke. The cylinder and water-jacket are cast in one piece. The exhaust and inlet valves are of a uniform size and are mechanically operated by a single set of cams and two to one gear wheels, which are encased in the main crank case, where they are efficiently lubricated. The cylinders are cooled by a water circulation maintained by a centrifugal pump and radiator. The drive is direct by a single chain to the live axle; two speeds and a reverse are obtainable by means of a concentric gear on the engine shaft. The gearing is simple and is enclosed in an oil-tight and dust-proof case. The reverse is operated by a pedal.



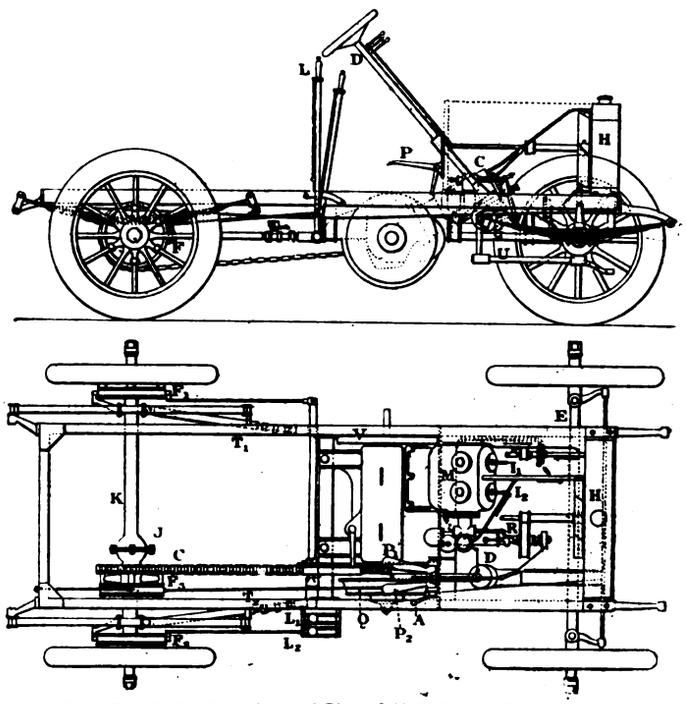


Fig. 76.—Part Sectional View of Motor of "Ford" Car.

When the controlling lever of the gear is thrown forward the transmission becomes locked with the fly-wheel, allowing everything to revolve at the speed of the engine, no gears being in motion. More or less speed is then obtained by a pedal-controlled throttle valve. The body is supported on four elliptic springs, and is entirely independent of the mechanism. It is made either as a two or four-seated car, the tonneau in the latter case being detachable. Artillery wheels, having 3 in. pneumatic tyres, are fitted, and the wheel base is 6 ft. and the tread 4 ft. 7½ in. The four-seated car complete weighs about 10 cwt. The vehicle has already earned an excellent reputation in America, and should soon become popular in this country, as among the many advantages claimed for it are its easy-running qualities and absence of noise and vibration.

MESSRS. A. W. GAMAGE, LIMITED, attracted attention to their motor-cars and motor-cycles, in which several useful improvements have been introduced with a view to increasing their popularity with the public. The "Gamage" voiturette with a 6-h.p. De Dion engine was on the stand. This is fitted with three speeds and a reverse, the drive being direct on the high speed, bringing all intermediate gears to rest. Transmission is by straight cardan shaft to the bevel wheel on the rear of the live axle. E.I.C. ignition is provided with trembler coil, and in order to facilitate attention to the engine the radiator, which is of the fan-cooled type, is carried in front and underneath the bonnet. A double-acting brake is fitted on the gear shaft, coupled to the clutch and controlled by pedal. Two double-acting brakes, acting on drums attached to the rear road wheels, are also provided. Attention has been paid to several minor fitments to bring the car thoroughly into consonance with British ideas, and, with its bucket seats and roomy tonneau, the new Gamage voiturette is one likely to be popular on the road during the coming season. As instances of the care with which the design has been studied, we noticed the good wide treads and the way in which the seating accommodation has been shaped to add to the comfort of the passengers. The Gamage motor-bicycle of 2¾-h.p. has long been favourably known to motor-cyclists, who will be interested in the firm's new machine, fitted with a 3-h.p. Fafnir engine.

The "Motobloc" cars, which have already been described in the *Journal*, made their first public appearance in England, and, though differing in many respects from the usual lines of cars, have, we learn, made a very favourable impression on the motoring public. MESSRS. MONTAGUE HAWNT AND CO., who are the British agents, displayed not only a *chassis* and an example of the motor, but a well-finished 10-12-h.p. *coupe*, and a two-seated racer which took part in the Paris-Madrid race last year. The general arrangement of the car, which for the present year is being confined to one size—10-12-h.p.—is shown diagrammatically in Figs. 77 and 78. It will be noticed that the motor is set at an angle to the ground, the explosion chamber being foremost, the cranks being at an angle of 180 deg. to each other. The cylinders are 110 mm. diameter by 120 stroke, the normal speed being 1,000 revolutions per minute. The water circulation is maintained by a pump and fan-cooled honeycomb radiator; the arrangement, however, is such that, should the pump fail, the circulation will continue on the thermo-syphon system. The change-speed gear, which gives three speeds and reverse, is enclosed in what is practically an extension of the crank case. The sliding pinions are mounted on an extension of the half-speed shaft of the engine, and the countershaft, on which the friction clutch is mounted, and which is in line with the crank-shaft, is connected with the rear live axle by a single side chain. The frame is of

Digitized by Google

pressed steel, and is adapted to receive any type of body, Fig. 79 depicting the tonneau de luxe.

Undoubtedly the largest and most imposing stand in the Exhibition was that of the BRITISH AUTOMOBILE COMMERCIAL SYNDICATE, LIMITED, which comprised an extensive display of Mercedes, Talbot, and Panhard cars. Fig. 80 illustrates the *chassis* of the 60-h.p. Mercedes 1904 car, which attracted considerable attention. The modifications, as compared with the 1903 type, have already been dealt with in the *Journal*, but it may briefly be mentioned that the main alteration is the abolition of the variable lift to the inlet valves. Passing to the Talbot cars, the 1904 models—8-h.p. and 11-h.p. two-cylinder and 20-h.p. four-cylinder—have already been described in these columns so far as concerns the mechanism. Fig. 82 shows the 20-h.p. engine, which, except for the number of cylinders, is identical with the 11-h.p. Differing from the 1903 motor, the valves are on opposite sides of the motor and are mechanically-actuated by different cam shafts. The inlet and exhaust valves are that previously customary, inasmuch as it is placed on the cylinder level instead of below the crank case, thereby facilitating examination. The carburettor, which is automatic in its action, is provided with a small air-inlet valve; as the speed of the engine is increased or decreased, the valve is opened or shut to permit a smaller or greater quantity of gaseous mixture to pass into the cylinders. The governor, which is, of course,

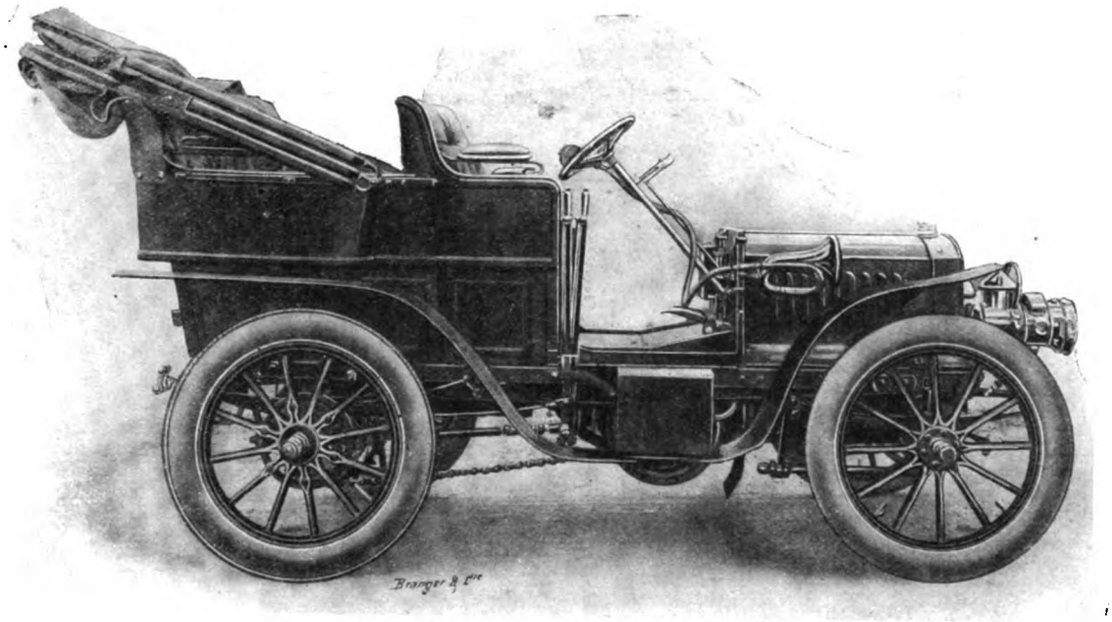

Fig 79.—The 10-12 h.p. "Motobloc" Tonneau de Luxe.

interchangeable. The bore and stroke of both sizes are exactly similar, and, therefore, whether in the 11-h.p. or the 20-h.p., the pistons, piston rings, cylinders, valves, connecting rods, bearings, half-time gear, pump gear, nuts, springs, bolts, etc., are identical in size. The ignition is by means of a rotary magneto designed to permit of advancing and retarding the sparking. The pump is gear driven, and its position is varied from adapted to act on the inlet, is arranged to come into action at a speed of 1,200 revolutions per minute. The water circulation has been so arranged that there is barely two feet of tubing. In the case of the 8 and 11-h.p. engines an ordinary radiator is used, whilst in the four-cylinder car a honeycomb cooler is employed, a fan being also provided to induce a current of air through it. Three speeds forward and a reverse are provided; and on top speed the power is conveyed directly to the rear axle without the interposition of any reducing gear. The transmission is through bevel-gearing and a cardan-jointed shaft, which is carried for the whole of its length in a phosphor-bronze bearing. The various designs of bodies fitted

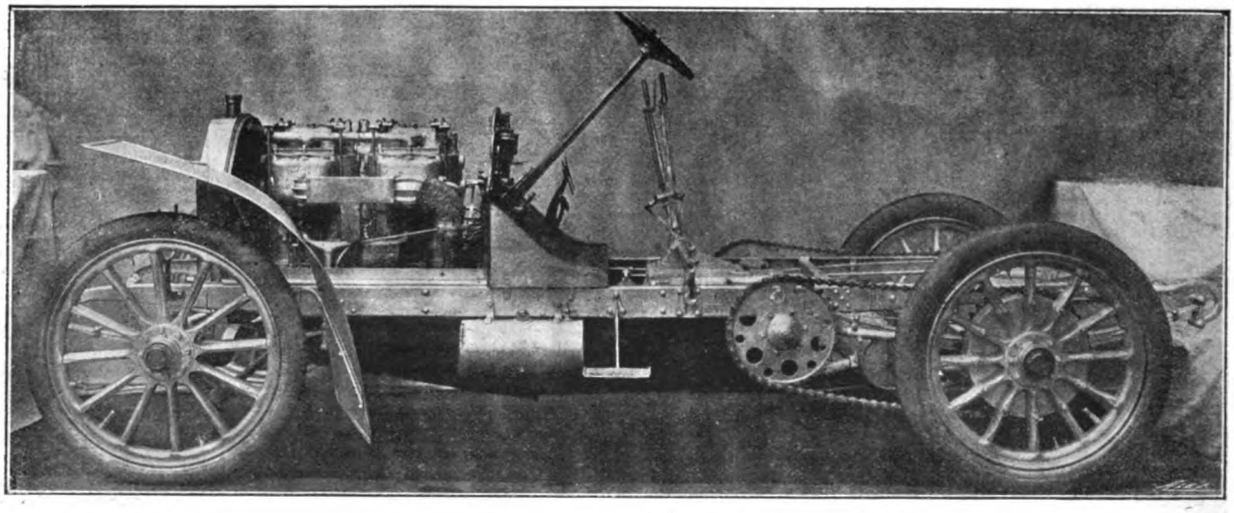

Fig. 80.—Chassis of 60-h.p. Mercedes, exhibited by the British Automobile Commercial Syndicate.

to the Talbot *chassis* are particularly noteworthy. Fig. 81 shows the 20-h.p. car with the standard tonneau body, the feature of which is the extra amount of knee room afforded to the rear passengers by the forward part of the tonneau curving outwardly instead of inwardly. We next examined a 20-h.p. Talbot with a Rothschild Roi des Belges double phaeton with side entrances, canopy, and front glass screen. The rear

Digitized by Google

part of the body extends up to the canopy by a curved detachable panel in which a window is formed to allow of an uninterrupted view to the rear. A continuous rubber-covered step is provided to the entrances to both the front and rear seats. Reference may also be made to a Talbot car with Rothschild single *coupe* body, and a 15-h.p. Panhard with a Shrewsbury side-entrance phaeton. Altogether the body work to be seen on this stand was of a very high order, while as to the mechanism of the *chassis* the names they bear are sufficient testimony of their excellence.

STIRLING'S MOTOR CONSTRUCTION (1903), LIMITED, were among the exhibitors of public service and heavy commercial vehicles, they having on view one of their 12-h.p. single-deck omnibuses to seat sixteen passengers, and a 12-h.p. two-ton wagon similar to those recently supplied to the War Office. As both of these have recently been illustrated in the *Journal* no lengthy reference is necessary on the present occasion. A large portion of Messrs. Stirling's stand was devoted to a display of motor-boats, a branch of business to which they are devoting great attention, having recently established a boathouse on the Thames at Strawberry Vale, Twickenham. Prominent among the boat exhibits were a 20 ft. Strickland canoe, fitted with a ¾-h.p. motor, and two beautifully-fitted launches of 18 ft. and 17 ft. respectively, with Stirling motors of 2-h.p. A feature of the latter is the large amount of internal space and seating accommodation. The motors, too, are interesting. A special device for timing the ignition is provided, the whole of the mechanism of which is enclosed in a little hinged casting, quite impervious to spray. A special patented silencer and exhaust condenser is also fitted. This consists of a square galvanised iron box, with a series of vertical tubes, situated centrally between an upper and lower chamber. Into the upper one of the latter the exhaust pipe from the motor curves upward from the forward side of the condenser, thus leading the gases up into this chamber first, whence they are led downwards and condensed in the vertical tubes, into the lower chamber, whence again they are led out into the escape pipe. There are no baffle-plates in the device, the result being an entire absence of back-pressure. The engine and magneto are completely enclosed in a spray-proof but well-ventilated wooden casing.

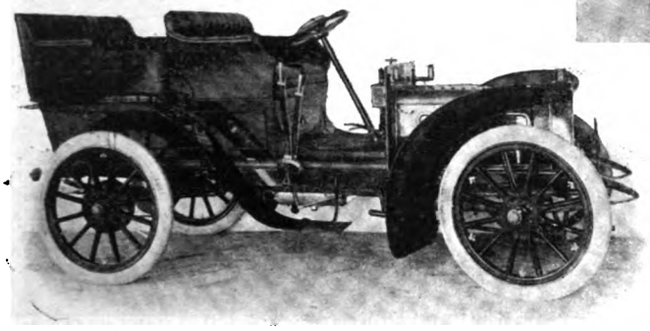

Fig. 81.—The Talbot 20-h.p. Car, with Standard Tonneau Body.

MR. A. W. MACLEOD, the London agent for the Cottereau cars, exhibited a *chassis* and a complete Cottereau car of the 1904 12-16-h.p. three-cylinder type. The frame of the vehicle is of stamped steel. The engine is an excellent specimen of workmanship, the three cylinders being mounted separately on a large crank case. The inlet valves are, of course, mechanically actuated, in accordance with modern practice, but, in addition to the throttle on the admission, the speed of the engine can also be regulated by means of a variable lift device fitted to the inlet valves. The cylinders are 95 mm. diameter by 120 mm.; the motor is exceedingly quiet in operation, as well as very elastic, any speed—from 200 to 1,200 revolutions per minute—being readily obtainable. All the bearings on the car are of the ball type. The gear is arranged to give three speeds ahead and one reverse, the top speed being a direct drive. The weight of the *chassis* complete is 15 cwt. A Cottereau "Populaire" car was also displayed. This is fitted with a single cylinder engine developing 7½-b.h.p., fitted with variable lift induction valve control as in the three-cylinder motor. Three speeds forward and one reverse are provided, the power being transmitted from the gear box by a central chain.

A light delivery van was exhibited by MESSRS. HAYES AND SONS, of Stamford, the motive power in which is supplied by a 6½-h.p. engine, the cylinders of which are arranged in the form of a V. The valves, which are all mechanically actuated, are of easy access, while the special form of carburettor permits of ready examination and adjustment. Another feature of the car is found in the transmission mechanism and the change speed gear. The latter is mounted around the differential on the rear axle, the power being transmitted to it by a cardan shaft and bevel pinion. The new gear, which is difficult to explain without a drawing, is very compact, and gives two forward speeds and a reverse.

The LIGHT CAR AND ENGINEERING COMPANY displayed a light car they have recently introduced to meet the demand for a popular price

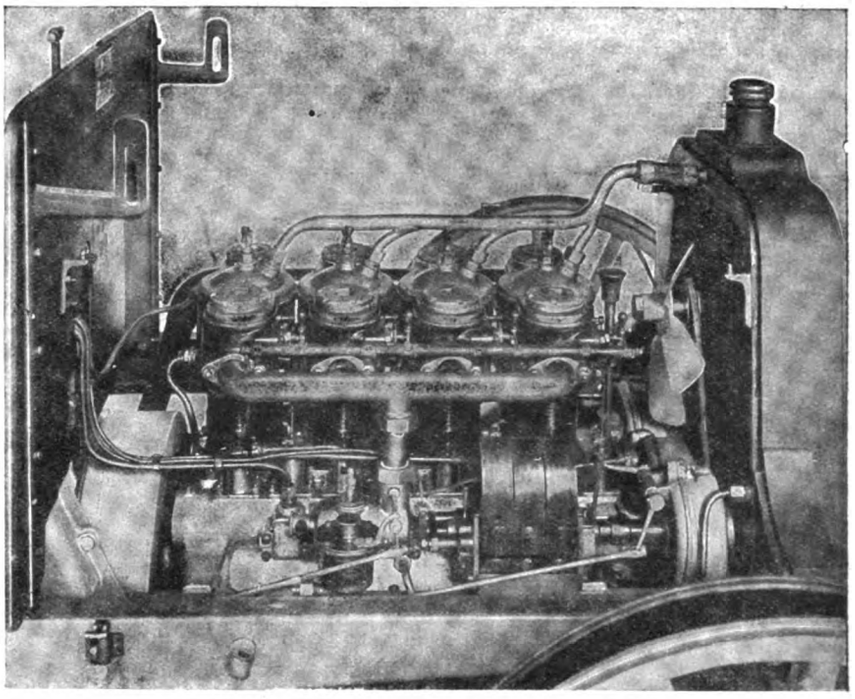

Fig. 82.—The Talbot 20-h.p. 4-cylinder Motor.

vehicle. The engine, which is set in the fore part of a wood and steel frame, can be either a 6-h.p. two-cylinder V-shaped air-cooled engine or a water-cooled vertical one of 4½-h.p., the circulation being, in the latter case, on the thermo-syphon system. The power is transmitted through a leather faced clutch and universal joint to a gear box giving two forward speeds and a reverse. The gears are, we noticed, of very large dimensions for a low-powered car. From the gear box a single chain transmits the power to the rear live axle. The various details appear to have been carefully thought out, with the view of rendering the parts accessible. The vehicle has a long wheel base, and, with inclined wheel steering and continuous mudguards, has a neat and attractive appearance. Specimens of the Sthenos carburettor and a new atomising carburettor of the firm's own design were also shown, as well as the Goodson igniter and sparking plug. This is of American origin, and comprises a magneto and a special plug, the latter consisting of an ordinary electro-magnet in conjunction with a pair of electrodes inserted in a cast-iron body screwed directly into the ignition chamber. The device is claimed to give a spark of constant strength at any and all speeds.

STEAM VEHICLES.

The LANCASHIRE STEAM MOTOR COMPANY, LIMITED, exhibited two heavy steam wagons—one of 4-ton and one of 6-ton carrying capacity. The former is of the standard type, and is intended for Messrs. Mann, Crossman, and Paulin, it being a third repeat order from this well-known brewery firm. The boiler is of the fire-tube central-feed type, having 85 square ft. of heating surface, and 3·2 square ft. of grate area, built for a working pressure of 200 lbs. per square inch. The distinguishing feature of the boiler is the ease with which it can be taken to pieces for cleaning purposes. It consists of an upper and lower shell, bolted about midway;

Fig. 84.—The Lancashire Six-Ton Tip Wagon.

the lower shell contains the fire-box, the crown of which is supported by a central tube, which is also used for feeding the boiler with fuel. Attached to the central tube is the top tube plate, the fire tubes being expanded in the furnace crown and the upper tube plate. The upper shell can be readily disconnected, which exposes the whole length of the tubes, which are of tough seamless steel. Attached to the top tube plate is a steam drier; washout plugs are arranged on the top plate and also at the bottom of the lower shell. A door is fitted in front of the boiler which admits of clinkering and lighting up. Under ordinary working conditions, i.e., when the gauge glass is half full, there is 14 in. of water above the furnace crown. For cleaning the tubes all that is necessary is to disconnect the chimney, which is attached to the smoke box top, the whole length of the tubes being then exposed for cleaning purposes. The engine is of the compound link reversing gear pattern, of 25-i.h.p., and is arranged so that both cylinders can be worked with high pressure steam, having independent exhaust. The cylinders are 3½ and 6½ in. diameter, by 6 in. stroke. Two speeds are provided, viz., 2½ and 5 miles per hour, with the engine running at normal speed. The change of speed is effected by the driver without dismounting. A simple arrangement is provided so that both wheels can be locked in case of necessity. From the differential shaft the power is conveyed to the rear road wheels by Renold roller chains. A special cushion drive is fitted in the chain pinion, by means of which the engine is allowed to make almost a revolution before giving motion to the road wheels. The driving wheels are of an improved composite pattern which dispenses with loose felloes and hubs. Briefly, it consists of a steel centre, on the periphery of which is fitted felloes and a weldless steel tyre. The rear wheels are 3 ft. diameter, the width of tyre being 8 in. The steering wheels are 2 ft. 10 in. diameter by 5 in. wide, of the gun-carriage pattern, fifted with steel hubs and phosphor bronze bushes. Among the recent improvements is the fitting of internal expanding brakes inside the chain rings on the rear wheels, they being thus protected from dirt. Fig. 84 shows the new 6-ton tip wagon exhibited. The boiler is similar in design to that in the 4-ton vehicle, but has 110 sq. ft. of heating surface and 4·9 sq. ft. of grate area. The engine is of the compound type, with Joy valve gear, which gives absolutely the same travel in either backward or forward direction. The steam valves are of an improved balanced flat pattern, without springs or other perishable material. The engine is of 45-i.h.p., the cylinders being 4½ and 7½ in. diameter by 7 in. stroke. A distinguishing feature of the engine is that the whole of the bearings are non-adjustable, the bearing surfaces being of such unusual dimensions as not to require adjustment for years, in which case renewable bushes can be inserted. It is claimed that by using non-adjustable bearings, not only are a considerable number of loose parts dispensed with, but the possibility of tampering with bearings by non-mechanical men is removed. Two speeds are provided, the transmission being by side chains. The driving wheels are 3 ft. 9 in. diameter by 10 in. face; the steering wheels being 3 ft. diameter by 6 in.

With the ever-extending use of motor-wagons for use in carrying heavy traffic along ordinary roads, and for delivery vans for lighter traffic, has arisen the necessity for an efficient and reliable steam generator or boiler for use in connection with such work. The difficulties in the way of designing a really efficient wagon are very great, in consequence of the various conditions which have to be met. These are:—Limit of weight, confined space at the engineer's disposal, high load efficiency to make the work profitable, and the indifferent quality of the roads over which a heavy load must often be carried. The ultimate result of many experiments and working trials of various types of boilers is, that most wagons are fitted with a vertical multitubular boiler, the tubes being fire tubes. This type will give a sufficient quantity of steam at 180 to 200 lbs. per square inch without "priming," and so dry that it is practically invisible when the exhaust is carried into the funnel. This boiler also comes within practical limits of weight, size, and cost. One of this type was displayed by MESSRS. T. BALMFORTH AND CO. It is shown in section in Fig. 85, from which it will be seen that provision is made against trouble through unequal expansion and contraction in various parts of the boiler, which is constructed for a working pressure of 200 lbs. per square inch. The heating surface is 90 sq. ft. and the grate area 3½ sq. ft. Every facility is afforded for cleaning out, while there are no resting places for sediment on the crown of the firebox. A large area of efficient heating surface is afforded, all practically below the water line. Referring to Fig. 85, it will be observed that instead of having perfectly flat tube plates, they are set at an angle of about 30 degrees, really forming the sides of two cones, the top one being inverted. The tubes connecting the tube plates are segments of circles curved to enter the plates exactly at a right angle. The result is that when expansion takes place the force does not, it is claimed, tend to compress the tube and thus spring the end joints, since compression is impossible. It tends instead to bend the tubes slightly, which easily takes place without in any way distressing the joints. As a matter of fact, it introduces an elasticity into the construction which is beneficial in more ways than the one just named, as it also stops any accumulation of hard sediment on the tubes themselves. The efficiency of the system is shown by the makers' statement that boilers comprising thousands of these bent tubes are now at work, and that no case of leakage has occurred, and not a single tube has needed "re-

K. Perforated feed pipe spraying the water into boiler.
M. Clinker door.
N. Chimney with outer casing and air-space.

expanding. By having the tube plates set at an angle it not only dispenses with a flat resting place for sediment, but induces a set or direction in the water circulation which constantly tends to wash or scour the tube plates. In addition, the tubes are spaced further apart, and three large cleaning doors are provided at equal distances round the shell in addition to the usual detachable casing. Infinitely better, however, than all possible provisions for cleaning is to prevent sediment going into the boiler at all, and to achieve this Messrs. Balmforth fit a patent live steam feed water heater and filter. This is a compact arrangement for passing all the feed

Digitized by Google

water through a heater, where it is raised to a temperature approximately that of the steam in the boiler. Long before it reaches this temperature the bulk, if not all the sediment is set free, and is deposited in a chamber provided for the purpose, and from which it can readily be removed. Between the depositing chamber and the boiler a filter is provided which stops the passage of sediment or dirt into the boiler. The water on leaving the heater is passed through the filter to the check valve, and is sprayed into the boiler through small holes in the circular feed pipe. During its passage through this pipe it is further heated and forced into the boiler in such a way that it washes the fire box crown, and sets up a rapid circulation, and being already heated considerably above boiling point, it is ready at once to ascend in the shape of steam globules. The effect is, that all the internal surfaces are kept clean, and the rapidity of circulation and consequently the steam capacity is greatly increased.

The AMERICAN MOTOR-CAR AGENCY, in addition to the petrol cars referred to elsewhere, exhibited two Toledo steam cars, one being a 6-h.p. standard runabout and the other a 7½-h.p. doctor's car fitted with hood and 3 in. Diamond single tube tyres.

The Gardner-Serpollet steam cars were represented by a 10-h.p. delivery van to carry a ton, and a side-entrance double-phaeton of the new 9-h.p. "Simplex" type, shown by the SPEEDWELL MOTOR AND ENGINEERING COMPANY. The latter is a new type for the 1904 season, and has a water capacity sufficient for a run of about 150 miles. The frame is of channel steel, the boiler at the rear being placed lower than usual. The engine is a four-cylinder one. Automatic pumps have been discarded, the water pump being actuated by an eccentric and rod from the rear axle. One lever controls a combined water and fuel distributor. The weight of the 9-h.p. *chassis* is between 12 and 13 cwt. All the mechanism, including the motor, is placed in the centre of the *chassis*. The car can attain a speed on the level of thirty-eight miles per hour.

The CREMORNE MOTOR MANUFACTURING COMPANY exhibited a new steam car which contained a number of interesting features. As we are preparing drawings to enable us to fully describe the car in an early issue, we postpone further reference to it on the present occasion. On the stand were also shown samples of the Cremorne Company's paraffin burners and regulators, four-cylinder horizontal and vertical steam engines, feed-heaters, seamless steel tank and fire-tube boilers. The Cremorne carburettor for petrol motors is dealt with elsewhere in the present issue.

GENERAL EXHIBITS.

THE HOFFMANN MANUFACTURING COMPANY, LIMITED, had a very fine display of steel balls made by their own patented process and guaranteed to within one ten-thousandth of an inch in diameter and sphericity. A novelty was an octagonal show-case containing a million balls of different sizes. The case, which with its contents weighed two tons, was mounted

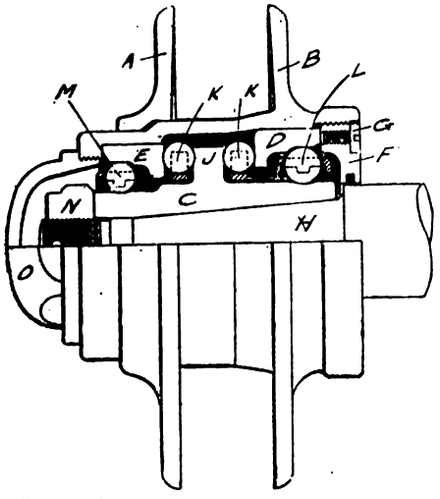

Fig. 86.—Section of Hoffmann Ball-Bearing Hub.

on one of the Hoffmann ball-bearings on a vertical axis, and visitors to the exhibit could enjoy the sensation of being rapidly spun round inside it. The exhibits included ball-bearings for every conceivable purpose, including quite a new type of motor-car wheel-bearing and step and thrust bearings of every description. Figs. 86 and 87 give part-sectional views of the ball-bearing hub for the wheels of motor-cars. As will be seen, there are four rows of balls, the outer rows L M taking the load, and the inner pair K the end thrust in both directions. In either case, the load is taken at right angles to the direction of rotation, so that a perfect rolling action is obtained without any spinning. The outer balls run between the hardened sleeve C and the two cups E and D. The sleeve is made to a standard taper and is fitted on the end of the axle and secured by the lock-nut N. The collar J, formed as an integral part of the sleeve, takes the side thrusts in each direction by the two rows of balls KK, running against the inside faces of the cups D and E, the adjustment being made by means of the screwed disc F locked up by the set-screw G. The design is such that each set of bearings keeps the other set true in their respective paths, so that any tendency to rub or jam against the side of the bearing is entirely obviated. The makers claim that this perfection of rolling action removes practically all wear from the hub, so that its life is to all intents and purposes limitless. The removal of the pin and nut N enables the wheel and bearing complete to be removed together. To facilitate this a service cap O is supplied in place of the usual brass cover cap, which, when screwed into the hub,

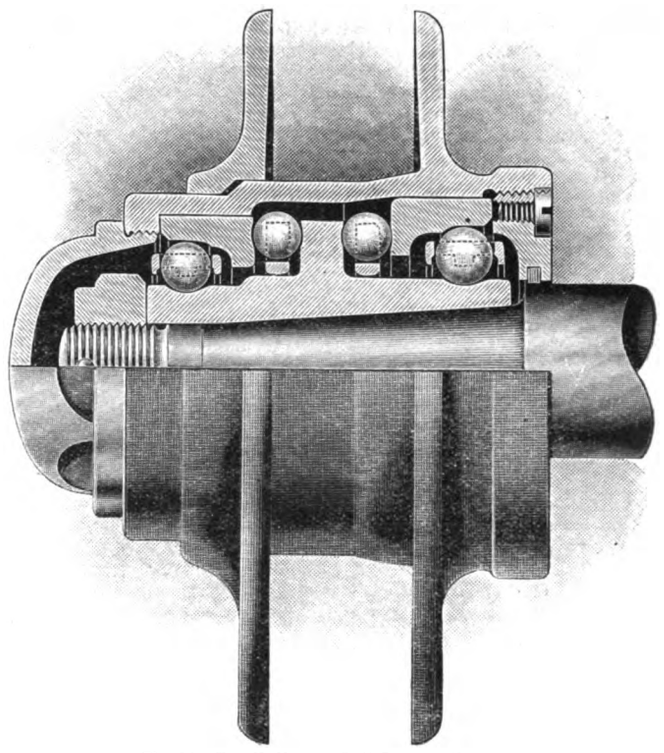

Fig. 87.—The Hoffmann Ball-Bearing Hub.

comes into contact with the end of the axle, and so draws off the cone All the balls are held in cages, so that if at any time the bearing has to be dismantled there is no danger of losing or misplacing them. The races E J are made of special steel, case-hardened by a patent process, leaving the face dead hard, but the interior of the metal only toughened. A set of these hubs were some time ago fitted to the wheels of a Panhard, and, after 5,000 miles' running, we are assured they show not the least sign of wear.

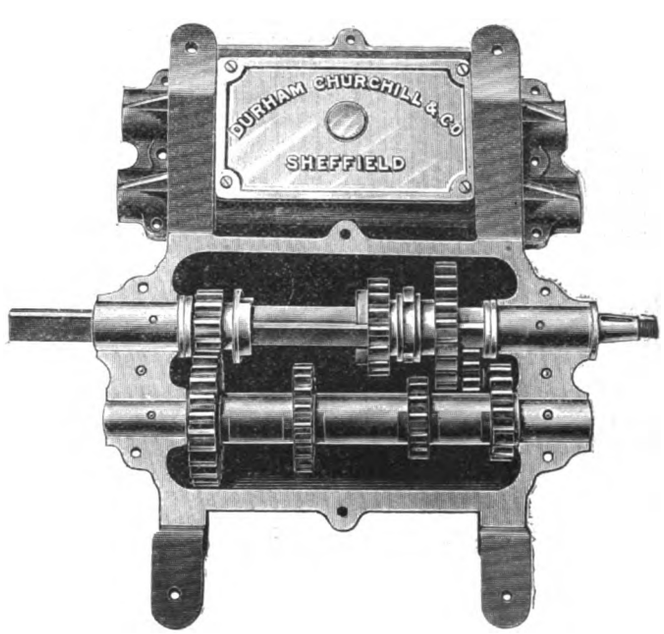

Fig. 88.—The Durham Churchill Change-Speed Gear.

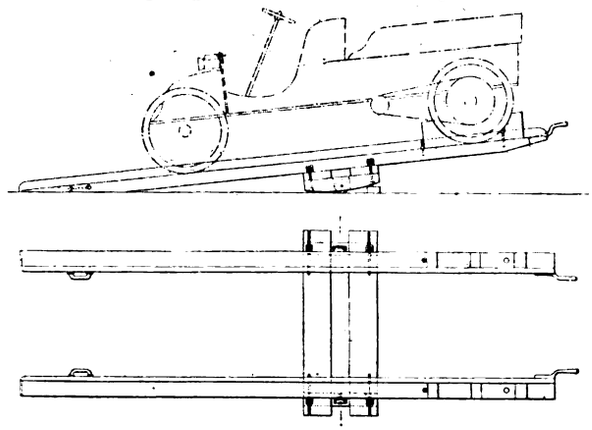
MESSRS. DURHAM, CHURCHILL AND CO. had a large stand which appealed more particularly to trade visitors to the Show, they having recently completed arrangements for the manufacture of complete sets of component parts for motor-cars of 5–8, 10-16, and 20-30-h.p., examples of *chassis* of the first two types being shown. Pressure of space prevents us referring

Digitized by Google

to all the articles exhibited, but we may mention a special metal-to-metal friction clutch designed for use in conjunction with engines, having no external fly wheel. Fig. 88 illustrates the Durham Churchill change-speed gear, which gives three speeds forward and a reverse. On the top speed the power is transmitted direct, the jaw clutches seen on the upper shaft being brought into engagement. Another interesting product is a metal-to-metal brake, intended to be fitted at the rear of the gear box. Live axles, bevel gears, spur differential gears, cardan shafts, front axles, steering wheels and gears are other articles made by Messrs. Durham, Churchill and Co. A live axle with special reducing gear, for use in connection with high-speed engines, is one of their latest productions. Suppose, for instance, that a 6-h.p. engine is fitted, the normal speed of which is 1,500-



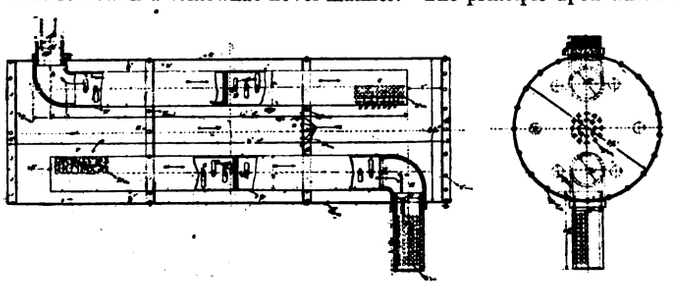


Fig. 89.—Elevation and Plan of Webb's Motor-Car Cradle.

r.p.m. If there is a reduction of 4 to 1 in the rear axle and a direct drive through the gear box, this gives, with 30 in. road wheels, a top speed of over thirty-three miles per hour, a rate at which it is unreasonable to expect a 6-h.p. engine to take a car and passengers of anything like average weight. To get over the difficulty they have designed an attachment which enables a change-speed gear having a direct drive on top speed to be used with such motors. The cardan shaft, instead of having a bevel-pinion at its rear end, has a spur-wheel meshing with a corresponding pinion on a short shaft on which the driving bevel is mounted. The reducing gear is entirely enclosed and suitably supported.

Considerable interest was shown in the motor-car cradle exhibited by Mr. W. R. Webb. This is a device to do away with the need of inspection pits. As will be seen from the diagrams shown in Fig. 89, it consists of two long special planks connected by cross pieces, the latter being mounted on rockers and also on castors. When it is necessary to examine or adjust any part of the car from below, it is run on to the path formed by the two planks. Then, by slowly rocking the car on the cradle, the latter can be jacked up to any desired height, the operation being quickly performed by a man and boy. Another advantage of the cradle is that, when the car is run on to it in the motor-house, the whole can be turned round by means of the castors, so as to be ready to run out when next required. The cradle will also be found useful by steamship companies having a number of cars to deal with, as, with a vehicle rigidly attached to a cradle, it can be hoisted into and wheeled to any desired part of the steamer.

In the Berner's Hall Mr. Stanley W. Andrews showed a new silencer for use of petrol cars. The apparatus, which is illustrated in Figs. 90 and 91, is constructed in a somewhat novel manner. The principle upon which it

Figs. 90 and 91.—Longitudinal Section and End View of Stanley Silencer.

is based is that of breaking up the exhaust gases, and retarding by allowing them to pass through pipes, across which a large number of pins are fixed diametrically, so as to form a kind of Archimedean screw inside it. In the silencer illustrated two of these pipes are fitted in a large expansion chamber, the gases from the engine passing into the box through the upper pipe, and ultimately finding their way out to the atmosphere through the lower one. Both pipes are studded with diagonal pins, which form two spiral passages through which the gases have to pass. The gases emerge from the upper pipe into the expansion chamber through holes at the extreme end, and are subsequently allowed to flow out through a perforated cap, after they have found their way through the entire length of the lower pipe. The silencer is claimed not only to give a quiet exhaust but also to cause no back pressure on the engine. It is made in sizes to suit engines of from 5 to 30-h.p.

Messrs. Lister and Sons exhibited their "Popular" 1½-h.p. marine motor, suitable for boats up to 14 ft. in length. Boats fitted with 2½-h.p. motors were also on view, presenting a very smart appearance. It is claimed for the "Popular" motor that it starts with the greatest ease, and runs with smoothness and regularity.

The See Motor Car Supply Company had on view the "See" non-skidding bands, which, being made of chrome leather with steel-studded treads, are claimed to be unpuncturable. The well-known "See" fluid and also the company's double-acting pump were on their stand.

Messrs. J. C. Fuller and Son, whose electrical batteries have long been familiar in all branches of electrical engineering, are now specialising on batteries for automobiles, and made a display which well illustrated their capacities in this connection. In the "Fuller" accumulators the grids are constructed to secure efficiency with lightness. Ordinary usage will not cause the paste or active material to rot, bulge, or become dislodged, and great care is taken with the general construction of the cases, the fine finish being a notable feature. The "Fuller" mercury bichromate charging battery has become well known among motor-cyclists and "men of moderate means." This is a very great convenience, and is proving as economical in use as it is serviceable. Ignition coils, test lamps, dry ignition batteries, accumulator covers, sparking plugs, volt meters and ampere meters were also shown, as well as a new spark coil with a patent high speed trembler.

In addition to their steam cars and steam-car accessories, the Cremorne Motor Manufacturing Company exhibited a new carburettor for motors using either petrol or paraffin as fuel, and of which a sectional view is given herewith. No float chamber is used; on the suction stroke of the engine the automatic valve EE¹ is pulled downwards from its seating, allowing air to gain access to the mixing chamber A, and at the same time uncovering the petrol inlet K¹ formed in the seating of the valve. Petrol is conveyed to this port by the pipe L, but the amount delivered through it upon the opening of the valve E is controlled by the adjustable needle K. The

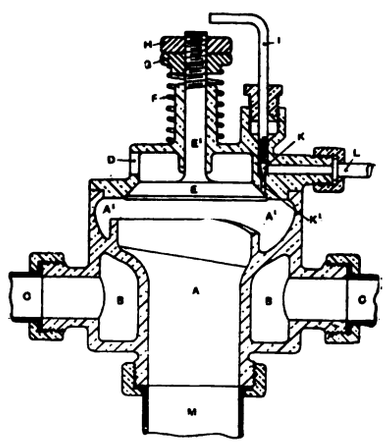

Fig. 92.—Section of Cremorne Carburettor

inner walls of the mixing chamber A are formed in the shape of a spiral whirl A¹. The air admitted in an outwardly sprayed form through the valve strikes into this whirl, courses round it, and picks up the petrol entering through the needle valve K¹, becoming thoroughly carburated in the mixing chamber A before passing on to the cylinder through the pipe M. The mixing chamber is surrounded by a jacket B, through which the exhaust gases can be made to pass. The faster the motor runs and the greater the suction the more the valve E opens, admitting a larger quantity of air, while the petrol feed remains constant, or nearly so, an automatic variation of the quality of the mixture being thus obtained.

Messrs. Cloud and Nichols had the "Buffalo" engine in a launch of their own construction. This has a float-feed carburettor containing a throttle for gauging the amount of vapour admitted to the cylinders. The sparking and throttling are easily regulated by a lever. These motors are made of 2, 5, or 7½-h.p. with two cylinders, or with four cylinders of 10, 15, 20, 25 or 40-h.p., and can be supplied with reversing gears or reversing propellers. A collection of sundry propellers and accessories for motor-yachts and launches completed an admirable display.

The Martin Pneumatic Tyre Company, Limited, had a good show of their motor-car tyres. The main features of this tyre are familiar to motorists, and the company is guarding its reputation by the maintainance of their good quality.

Pratt's motor spirit is too well known to need detailed description on the present occasion. Suffice it to say that the Anglo-American Oil Company drew attention to its merits in the Hall, and enabled motorists to judge of its merits in the yard at the Barford Street entrance. Oils for lighting and other purposes were also exhibited, as well as cans of an improved design for the conveyance of motor spirit in compliance with the regulations of the Local Government Board.

Digitized by Google

In our issue of the 5th ult. we described the Reilloc tyre, brought out by MR. ARTHUR COLLIER. Hence some of the interest with which the new device was regarded at the recent Show. This has attracted much attention, and, being akin to both pneumatic and solid tyres, seems to provide some chance of settling a problem that has troubled motorists many a year. It is really a detachable solid tyre, having an outer cover secured to the wheel much in the same way that a pneumatic tyre is fixed. There is an inner

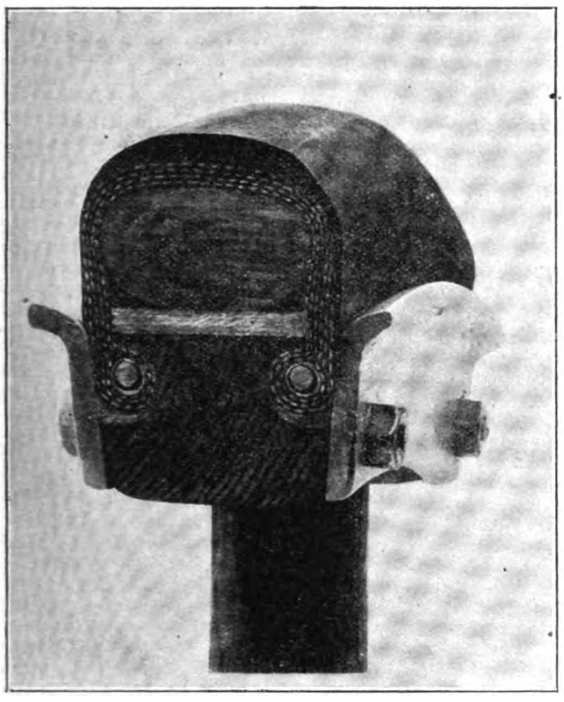

Fig. 93.—The Reilloc Padded Solid Tyre.

rubber pad, and as soon as the outer cover is worn down to this the latter can be renewed. The accompanying illustration, Fig. 93, gives a good idea of the form of the Reilloc tyre.

All kinds of electrical accessories for automobiles were shown by MESSRS. J. LACOSTE AND CO., some of whose specialities, notably the induction coil, have recently been fully described in the *Journal*. Here were to be seen dry batteries, charging boards, induction coils, coils with magnetic tremblers, ignition controllers, advance sparking apparatus, and contact-breakers of a good pattern, including detachable ones, which can be instantaneously removed. In these the blade and aluminium base slide on a groove, and can be lifted from their place for adjustment or the cleaning of the trembler. Spark intensifiers, switch handles, stop-watches of a more reliable character than those usually appearing in the police court, and sparking plugs were also included in a really excellent display.

At the stand of MR. C. LOHMANN, whose connection with the making of motor-cycle saddles, tool-bags, and the like is well known, was a good selection of lamps, bells, horns, accumulators, and similar goods identified in the trade by the name of "Perfecta." Among the many sundries which contributed to the representative nature of the exhibit was the "Bonworth" tyre gaiter, a neat and useful speciality in chrome leather, which must be added to the list of devices recently introduced in connection with the tyre problem. Headlights formed the staple interest of the display of the TWENTIETH CENTURY MANUFACTURING COMPANY, whose varied show of lamps deserved attention. They had a display of horns, and exhibited a new mica plug, the use of which will be watched with interest. The "Licorne" motor sidelight, a well-designed lamp, was among the assortment at the stand of MESSRS. STEINER AND CO., whose lamp stock is comprehensive in every branch. Horns were shown in great variety, with various fastenings, enabling the same to be fitted to any make of car. Patent clips for affixing horns and lamp brackets are among the minor details of a useful display, in which was also a large number of motor-cycle stands, lamps for motor-cycles, folding foot-pumps, etc.

A 12-h.p. *chassis* was one of the most important exhibits made by MESSRS. PHILIPP AND CO. It is proposed to have this made in England throughout and that on the stand was fitted with an engine by Messrs. Lloyd and Plaister, whose sole agency for this country has been obtained by Messrs. Philipp and Co. The frame is of pressed steel, and a Longuemare carburettor is also provided. The front axle is of the new hollow type, a cardan live axle and Panhard type of speed gear being among the other features of a *chassis* which should prove of service to firms anxious to go into the motor-car business. Among other exhibits was a cardan driving axle and hubs with double ball bearings, a brake drum and an internal expanding brake. The Lloyd and Plaister motor was also exhibited apart from the *chassis*. This is made with a double cylinder of 10-h.p. or four-cylinder of 20-h.p., with mechanical inlet valves. The inlet valve gear is arranged to give a variable lift. Motor axles, carburettors, axles of English make, radiators on the honeycomb system, condensers for steamcars, hand steering wheels, centrifugal water pumps, and severale xcellent types of lubricators completed a varied and useful display.

A non-slipping cover for automobile tyres was shown by MR. W. MAITLAND EDWARDS. This consists of a toughened chrome leather cover moulded so as to fit the tyre exactly. Along the thread are steel segments stamped so as to conform to the shape of the tyre. These are riveted with bifurcated rivets at intervals half an inch apart, the segments projecting above the tread of the tyre sufficiently to ensure a firm and continuous grip of the road surface. The segments are made of tool steel, and the idea is one that will be watched with interest by all anxious to solve the problem of skidding.

A very interesting display of petrol motors was made by Mr. F. C. BLAKE, ranging from 3 to 40-h.p. They are designed for use on motor-cars and launches, the latter being a branch to which Mr. Blake is devoting considerable attention. The 12–18-h.p. engine has the four cylinders cast in two pairs. Fig. 94 illustrates the 40-b.h.p. engine designed for use on auxiliary yachts and petrol locomotives, it being built rather more substantially than a motor required only for car work. It is fitted with mechanically operated inlet valves driven off a separate cam shaft. The cylinders are cast in pairs with water jackets in one piece. A governor acting on the throttle is provided. The engine is of the slow-running type, 40-b.h.p. being developed at a speed of 550 revolutions per minute. Separate adjustable bearings are placed between each throw of the crank shaft. All working parts are enclosed and automatically lubricated. Mr. Blake has recently introduced a new design of motor in which the inlet valves are located on the top of the cylinder heads, and actuated mechanically by rods and tappets. These are made in two sizes—25-h.p. and 18-h.p., the latter having four cylinders, cast in two pairs, 105 mm. diameter by 120 mm. stroke. The normal speed is 750 revolutions per minute; the valves are so arranged that they may be readily taken out when necessary, it only being necessary to remove one nut to withdraw two valves. Mr. Blake was one of the first to recognise the necessity for providing large inspection doors to the crank chambers, which are to be seen in all his motors, even in the small 3-h.p. single-cylinder type. Other exhibits included motor bonnets, petrol and water tanks, radiators, accumulators, commutators, and induction coils. Among the latter was a new one designed to work at a very high speed, and in which there is only half the usual weight of secondary winding. The condenser is of double capacity, while the diameter of the primary winding is also increased. The special novelty is found in the mounting of the trembler blade on a steel blade set in torsion between two vertical supports—one of the attachments of the

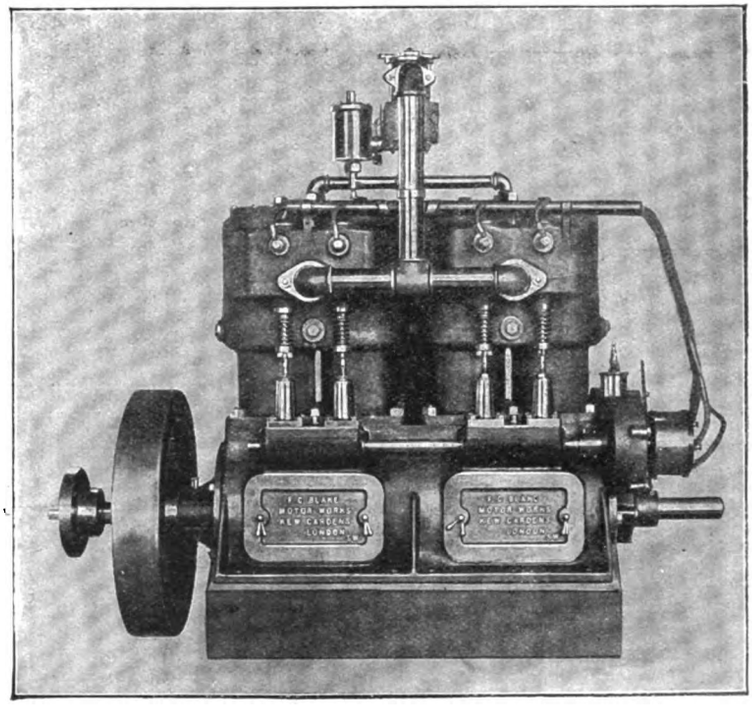

Fig. 94.—The Blake 40-h.p. Four-Cylinder Motor.

primary—the two blades thus forming a T, and the free end of the trembler being situated beneath the set screw with platinum points in the usual way. The effect of this special construction is that the amplitude of movement of the trembler is reduced to the minimum, and consequently its vibratory speed increased in inverse ratio. It is claimed that if an engine could be run at 6,000 r.p.m., this coil would still spark it without missing a stroke.

Messrs. Purrott and Willard's appearance at the show has given another demonstration of the ability of Birmingham manufacturers to turn out lamps of ingenious design as well as of good workmanship. They have a high-speed self-contained headlight constructed for use on fast travelling cars, which has a column of air at the rear of the reflector serving the admirable purpose of keeping the lamp cool. This has some good features in the minor details which constitute real improvements in the result. Another good type is a paraffin tail lamp that will not blow out, as has been proved by actual experience on a car travelling at forty miles an hour. The Beam headlight is a self-contained lamp made by Messrs. Purrott and Willard in brass or nickel-plated metal, and, with a 6-inch face, can be depended on to give a good light for six hours. The firm are studying the

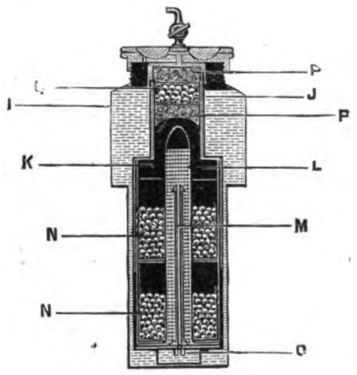

Fig. 95.—Section of Purrott and Willard's Acetylene Generator.

regulations of the Local Government Board with a view to bringing out a headlight in which the light can be reduced about 75 per cent. by means of a lever fitted to the dashboard. In connection with these lamps an acetylene generator has been brought out, which has the advantage of being entirely automatic in action and clean in use. As will be seen from the accompanying illustration, there is nothing to get out of order. I. is the outside of the water tank, J. the bell cover, K. the gas chamber, L. the perforated carbide carrier, M. the water feed pipe, which is fitted at the top with a spreader to secure a regular action of the water; O. the screwed end of the water feed, to take connection for cleaning; R. the wool wads in the main purifying chamber; and Q. the charge of carbide for purifying the gas; N. are cartridges charged with carbide. These latter are Messrs. Purrott and Willard's ingenious idea for supplying calcium carbide in sufficient quantities for burning two, three, or any other number of hours. The top and bottom of the cartridge has a lever lid which can be opened with a coin, the perforated carrier (L.) being projected up, as shown in the sectional view. Thus a generator of efficiency and cleanliness is provided which can be readily placed in the lamp, and forms a most compact device. The residue or sludge does not collect in the gas chamber or water tank, but is confined to the cartridges which are discarded when spent. In addition to their interesting collection of lamps, Messrs. Purrott and Willard also had a display of door furniture, coach beading, and brass and plated work of similar kinds for body builders.

A new comer to the exhibition was the R.L. Motor Engineering Company, Limited, who, as already mentioned in these columns, had a display of general interest to those on the look-out for motor-vehicles of a cheap price. That their exhibits were appreciated was apparent from the cards with which the cars were embellished as the week wore on. The Rulex car is fitted with a 3½-h.p. motor, with a direct drive by Renold roller chain to the countershaft. From this is a chain drive to the differential axle. For the two-speed gear a patent has been applied for. The combined hand brakes give unquestioned power in that respect. The car can be geared up to forty miles per hour. It has petrol capacity for more than two hundred miles, and with its wheel steering presents an up-to-date appearance. Not only is there ample seating accommodation for two passengers, but plenty of space is left for baggage, spares, etc. Another car brought out by the R.L. company is fitted with the 4½-h.p. Rulex water-cooled engine. This is finished in high-grade material, and well adapted for the growing demand for a light two-seated car. In addition to the cars, the company also showed one of their Rulex motor-cycles. These are made in various sizes, from 2½-h.p. upwards; the 2½-h.p. machine having a cylinder capacity of 70 mm. bore by 80 mm. stroke. The engine is mounted vertically in a weldless tubular frame; a Longuemare carburettor is fitted, as well as the R.L. company's aluminium wipe contact breaker, which is made dustproof and to run in oil. This cycle is fitted with the "Allways" free or swinging crank, which is a combined foot rest and pedal. It acts on a positive clutch, and is so simple that there is claimed to be no possibility of it getting out of order. This crank can be fitted to any ordinary bicycle or tricycle as well as motor-cycles. A patent speed gear with free engine was also shown, and the exhibit was, as we have said, of considerable merit and interest. The R.L. company have every equipment for the production of high-class work, and are evidently determined to reap much of the growing automobile trade.

Messrs. Henry Johnson and Sons, who have devoted time and trouble to the problems associated with the packing and transport of automobiles, took advantage of the Exhibition to make known this feature of their shipping and forwarding business. So, too, did Messrs. G. W. Sheldon and Co., insurance freight and passage brokers. They have had considerable experience in the shipping of motor-cars, wagons, lorries, and automobile accessories to all parts of the world.

The Clarendon Motor-Car and Bicycle Company, Limited, had on view a number of their 3-h.p. "Clarendon" motor-bicycles, the feature of which is found in the engine, the driving pulley having an adjustable outside bearing. The bore and stroke of the motor are 77 by 81 mm. respectively. A mechanical inlet valve is one of the improvements for this season, as also an effective silencer. One of the machines is fitted with a neat fore-carriage. The Clarendon Company also exhibited a 4½-h.p. water-cooled motor, with mechanically-operated inlet valve.

The Sola accumulator was shown by the company of that name, for whom Messrs. Horner and Sons are wholesale agents. The traction batteries are made in various sizes, and will run a car from twenty-five to sixty miles. A special high-charge battery for petrol cars, which can be recharged in three hours, was also on view. The company's Sola ignition batteries are made up in celluloid or vulcanite cases, and have attained considerable reputation for reliability.

The exhibit of the Roots Oil Motor and Motor Car, Limited, was interesting, inasmuch as the cars are fitted with internal-combustion engines using paraffin as fuel instead of the lighter and more costly petroleum spirit. The exhibit comprised a *chassis*, a two-seated car and a 5 cwt. delivery van, all of 5-b.h.p., and built for the Roots Company by Messrs. Armstrong, Whitworth and Co. The frame is hydraulically pressed to a channel section out of sheet steel. The motor, of 5-h.p., has a single cylinder of 4·9 in. bore and 5 in. stroke. It is placed in front of the car under a bonnet, the crankshaft being parallel with the axles. The motor uses ordinary kerosine or paraffin oil, and is adjusted to run at 760 revolutions per minute. The engine has a higher compression than hitherto; it is provided with electric ignition either by accumulator or by magneto. To maintain the heat of the vaporiser while running on electric ignition, it is fitted with a jacket, through which the exhaust gases are made to pass ere reaching the silencer. To start the engine the vaporiser is heated by a blow lamp for three or four minutes, as in the earlier type of engine, but immediately the engine is running it can be put out, so that there is no external flame, the motor continuing to run upon the electric ignition alone. The speed of the engine as also the advance sparking is controlled by a small lever on the steering standard. An aluminium alloy cover is provided for the motor-valve mechanism, also for the magneto gear, and a leather shield is fitted under the motor, to prevent dirt and mud collecting on it. The water circulation is maintained by a semi-rotary, positive-acting pump driven off the half-speed shaft, and radiator. The lubrication of the engine is by a pump, forcing oil at a considerable pressure to the main bearings of the crank, to the crank pin and to the piston rod bearings through holes bored in the crank and connecting rod. The motor drives by means of a leather-laced friction clutch and a Renold chain to the gear box, providing three speeds forward and a reverse. From the second shaft of the gear box

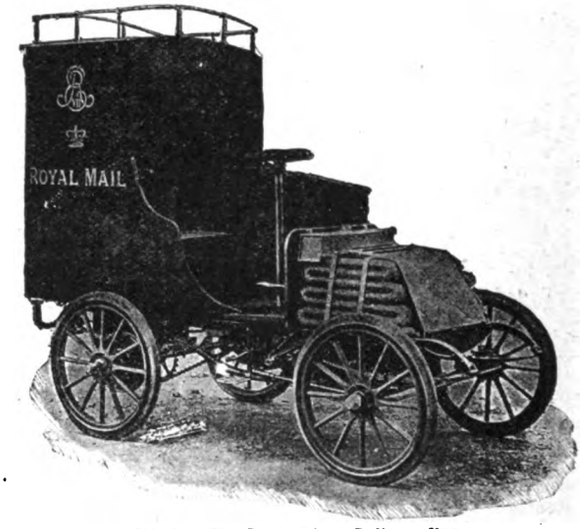

Fig. 96.—The Roots 5-h.p. Delivery Van.

a roller chain drives the rotating back axle, upon which the differential gear is fitted. Two pedals are provided—one for releasing the clutch, and the other for operating the band brake on the gear box. The second brake is fitted to the differential gear box on the back axle. Artillery wood wheels, having a diameter of 30 in., are fitted to both front and back axles, and shod with solid rubber tyres, or pneumatics, as required. The car has an overall length of 8 ft. 3 in., and weighs, complete with oil and water, about 10 cwt. Fig. 96 illustrates a Roots 5-h.p. delivery van, which has been carrying the mails every night between Newcastle and Sunderland *via* South Shields for some time past, and which is sometimes loaded up to 8½ cwt. This van has now done nearly 6,000 miles of regular nightly running, on solid rubber tyres, an excellent test of its reliability.

(*To be concluded.*)

CORRESPONDENCE.

"JOBBING" A MOTOR.

To the Editor of *The Motor-Car Journal.*

Sir,—May I trespass on your valuable space for the purpose of drawing attention to the enormous prices asked for hiring a motor-car? I am extremely interested in motors, and I much prefer them to horses; indeed, I should be very glad to give up my carriages and horse in order to keep a motor for my work were it possible for me to be guaranteed that the cost would not be greater. This, however, seems to be impossible, as I can job a brougham Victoria, horse and coachman, etc., for £250 a year, whereas I am asked £1,000 a year for a motor-car!

For many reasons most members of my profession in London prefer to job their carriages and horses, and so long as there is this great difference in cost between carriages and motors I do not think that motors will become very general with us. On the other hand, I believe that if a quiet-running petrol landaulette could be hired by the year at about the same price as a horse and carriage, there would be a very great demand for it. There seems to be a lack of enterprise on the part of motor-car firms, and one is almost led to suspect a distrust of the behaviour of their cars, since they all seem adverse either to spreading the cost of the car over two or three years or to fixing a moderate rate for hiring.

I have some reason myself for hesitating to buy an expensive landaulette and run it myself, as I have owned a small motor-car for the last year, and it has proved an expensive and rather uncertain luxury.—Yours truly,

Surgeon.

MOTOR-RACING ON ENGLISH SHORES.

To the Editor of *The Motor-Car Journal.*

Sir,—Filey is within reasonable distance (about forty miles) of York, and seven miles south of Scarborough. The road to York is well known, and from York *via* Malton to Scarborough it is very good. On the south side of Filey is Bridlington. There is a good road on the coast from Scarborough to Filey, and, although Filey itself is a small place, there is excellent accommodation both at Scarborough and Bridlington for motorists. I have cycled and motored all over this district and cannot agree that Filey is inaccessible.—Yours truly,

Yorkshireman.

PROPOSED LAMP TEST.

To the Editor of *The Motor-Car Journal.*

Sir,—Referring to Mr. E. Baedeker's letter on the above subject, in your issue of 19th ult., we think his suggestion a capital one and well worthy of the serious consideration of the A.C.G.B.I. Writing as manufacturers who have devoted both time and money in the endeavour to produce lamps that would meet the requirements of the motoring public generally, we beg to say that we welcome the proposition, and will do all in our power to support it.—Yours truly,

Purrott and Willard.

THE GOVERNED ENGINE.

To the Editor of *The Motor-Car Journal.*

Sir,—It seems quite probable that governors on four-cylinder engines will soon disappear. At its very best the automatic governor was usually a nuisance, and always required looking after; and what purpose did it serve? The engine would run slowly under its action, and when changing speed it prevented the engine from racing. That is all the governor does, and it can easily be done in a far more simple manner. A graduating throttle valve is fitted on the induction pipe, controlled by a small pedal, and from the steering wheel as well, very often. The normal position of this pedal is up, in which position the throttle-valve is only just open wide enough to keep the engine running slowly, and by pressing the pedal down the throttle is opened; the moment the pedal is released the engine is throttled. One of the latest French cars is fitted with an arrangement of this description, the governors being done away with. It would be interesting to have the opinion of other readers as to the advisability of fitting governors.—Yours truly,

Annamoe.

STEAM *V.* PETROL.

To the Editor of *The Motor-Car Journal.*

Sir,—Will "Another Steamer" and "Paraffin" give a description of the burners they use on their Locomobile cars? I have such difficulty in storing petrol that my car is almost useless to me, and should be glad to alter to paraffin if reliable and free from clogging up of the vaporiser.—Yours truly,

Locomobile.

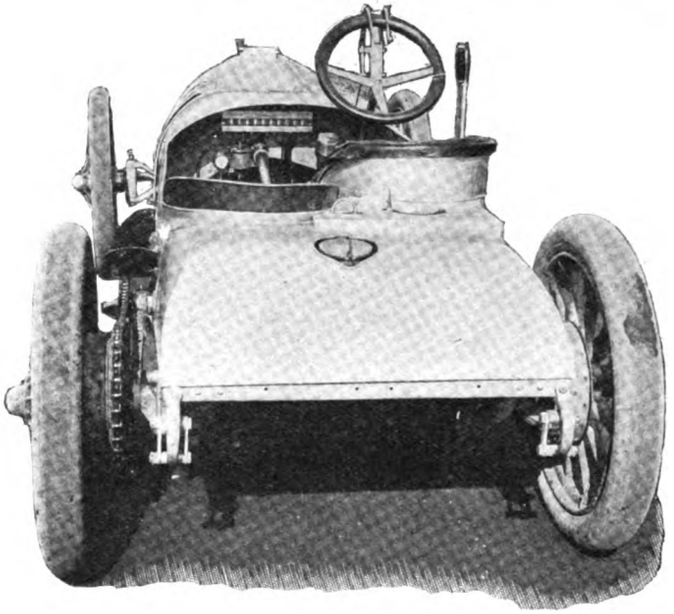
STEAM CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—As I have had considerable experience with Stanley steam cars, I should like to tell "Northern Steamer" some points about these vehicles. They are a great improvement on the type of American light steam car usually known to the public. The boiler is almost the same as the Locomobile type, only the working pressure is 400 lbs. per square inch; superheated steam is used, and a direct gear drive on the differential from the engine. The gear wheels show little signs of wear after nine months' use. As one of your correspondents said, it is a treat to drive one of these cars. The only real trouble I have had is the back tyres bursting, which I consider too light for the speed of the car. I have averaged twenty miles per hour for 200 miles.—Yours truly,

H. W. T.

To the Editor of *The Motor-Car Journal.*



Sir,—I notice "Another Steamer" is inquiring for an automatic arrangement to cool the seat in warm weather. I find it beneficial to raise the cushion of seat by laying two strips of wood 1 in. by 2 in. across the seat and turning the apron back; it allows the air to blow through under the cushion. With regard to the water tank getting very hot without exhaust, I find it a saving to let the water get as hot as it will if only the pump will lift it. If it gets beyond feeding point I add one or two buckets full of cold water. If "Another Steamer" is using an injector he may find it very troublesome with hot water. I should like to know the best type of burner on the market, as my Clarkson's needs some repair, and if there is a better I might change.—Yours truly,

Steamer.

A MYSTERIOUS NOISE.

To the Editor of *The Motor-Car Journal.*

Sir,—I should be glad if you or any reader of the *Journal* could assist me in overcoming a difficulty experienced in my car. It is fitted with a 6½-h.p. Aster engine, and when I put the car on top speed it knocks or gives a sharp clink every time it fires, no matter how much I retard the sparking.

Rear View of the Wolseley 72-h.p. Gordon Bennett Racer (*See last issue*).

The moment I put it on the lower speeds the clinking stops. It is only on the top speed that this happens, even when the car is going full speed.—Yours truly,

Dermatine.

AN ELECTRICAL BATH CHAIR.

To the Editor of *The Motor-Car Journal.*

Sir,—We have an inquiry from one of our customers for an electric Bath chair, capable of travelling at a speed of about six miles per hour, and the batteries capable of holding sufficient charge to travel twelve miles. Do you know of anyone making such a vehicle? If you do, we should feel obliged if you will put us in communication with them. We saw one at one of the shows held at the Agricultural Hall some three or five years back, but unfortunately we cannot trace it.—Yours faithfully,

D. W. and Co.

[We remember the vehicle in question, but it is, we believe, not now on the market. If any firm makes a Bath chair of the type described we shall be glad to put them in touch with our correspondents.—Ed. *M.C.J.*]

THE RULE OF THE ROAD.

To the Editor of *The Motor-Car Journal.*

Sir,—Your correspondent, Colonel Magrath, in his letter in the *Journal* of the 26th ult., does not realise the pedestrian's point of view. The reason why vehicles should keep to the left and people on foot to the right is that the latter can see all vehicles coming the other way, on their own side, and, by keeping closer to the hedge, can pass in safety.

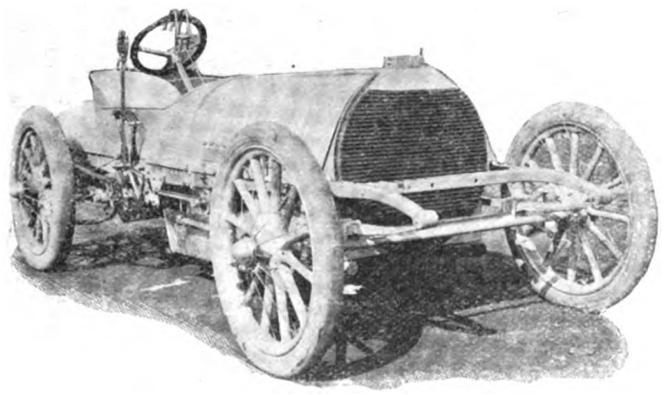
If there were footpaths everywhere it would not matter; but, at present, not one mile in every thousand of ordinary roads possesses a footpath.—Yours truly,

Ronaleyn.

Digitized by Google

LOSS OF POWER ON OLDSMOBILES.

To the Editor of *The Motor-Car Journal.*



Sir,—A few weeks ago a letter appeared on this subject, which I noted, because I was in the same trouble with my Oldsmobile. At last I discovered the cause in a play of $\frac{1}{16}$-inch in the inlet valve gear, owing, I suppose, to wear. A bit of $\frac{1}{4}$ thick sheet brass put temporarily under the end of valve stem had a marvellously enlivening effect, and a larger pulley on one end of the valve lever made this permanent.—Yours truly,

J. Brown.

DRIVERS.

To the Editor of *The Motor-Car Journal.*

Sir,—I have been interested in the correspondence *re* driver-mechanics, and would like to reply to "One with the Times." He remarks that driver-mechanics seem eager to enter private service. I will say that he is perfectly right when he states it is because they are not efficient for the workshop. Some of the "so-called driver-mechanics" are no more efficient for the workshop than the ex-coachman. He also remarks that mechanics do not turn out cars so smartly as the ex-servants. Probably not to outside appearance; but, as regards the mechanism, I contend the ex-coachman, or valet is not half so smart as the mechanic, because the ex-coachman or valet has not had the practical experience, and the mechanic knows exactly what ought to be done as regards oiling round and general care of the engines, etc. He also states that he does all his own repairs, unless it is a job for the lathe. I very much question that statement, and would like to see him shape to make a drill or use a file. I expect the job would be a bit humpbacked when done with. I also would like to reply to "A. L. R." *re* the question of "decent wages." I might state that I can go into any engineering shop in London, providing men are wanted, and as a fitter or mechanic earn the standard rate of wages paid in such shops, 39s. or 40s.,

Front View of the Wolseley 72-h.p. Gordon Bennett Racer (*See last issue*).

as the case may be, for fifty-four hours per week, and not have any responsibility attached to my services, because there is always someone in charge to give orders, and there are scores of driver-mechanics who are also qualified to do likewise. And "decent wages" depend upon the hours to be worked. A competent driver-mechanic, able to do his own repairs, and who studies his employer, ought at least to receive 45s. per week, Sunday not included, as mechanics get double pay for Sunday work in engineering shops, and some railway employees receive double pay, others time and a half, for Sunday duty. If anyone doubts my statements I can prove it, as I have had eleven years' experience on different railways. And I consider that an employer who gets a good driver-mechanic such as I have stated will find it cheaper in the end than the cheap ex-coachman who has to send out repairs.—Yours truly,

Driver-Mechanic.

To the Editor of *The Motor-Car Journal.*

Sir,—I have noted for some little time the caustic remarks of "mechanics" against the valet or coachman-driver, and strongly uphold "One with the Times" in taking up the cudgels in defence. They seem to think they are the only intelligent persons about, and that no one has any right to undertake such a stupendous undertaking as the charge of a car except themselves. I contend that there are quite as many good servants as mechanics whom it would pay over and over again for masters to engage, as they would get honest service, in addition to being held in respect, and I think if a man likes the work he would take the utmost pride in his car. As regards "Public Service Driver," his delightful assurance that "this class of mechanic" are delighted to get a berth at 30s. a week, where they only got £1 before is absurd. I am getting at the present moment £60, all found, as butler, which is considerably beyond the £1 a week. I have put in some months in motor works last summer, and am prepared to take a situation at a moderate wage, and to do my best for any gentleman and his car when the opportunity occurs, simply because I like the work so much; and there are others, many of them, like myself, waiting an opportunity, so that "Public Service Driver's" remarks are most undeserved and out of place. More respect for the man who does not mind making himself useful in any way in spare time, and perhaps it is the fear of not being so independent as formerly that makes them so virulent.—Yours truly,

A Motor Butler-Valet.

To the Editor of *The Motor-Car Journal.*

Sir,—It has often been proposed that someone may suggest some scheme, which would give owners in want of a really good driver-mechanic the opportunity to find such a man, who, as some of your correspondents state, seems hard to find, where as week after week brings new letters from men who seem to have the best of credentials.

I suggest that there should be an organisation of thorough practical driver-mechanics to which only such men should be eligible as members who could prove their abilities by good references. The organisation should be represented by a good man to act as secretary, whose business it should be to

(a) take up say three references to show that the candidate has practical experience as a mechanic;

(b.) that he has held a driver's berth, and

(c.) that he has not been dismissed from any of his situations for gross misconduct or inability.

An entrance fee of a certain sum would have to be paid, as also a monthly or quarterly subscription.

Situations to be filled by members only, for which they would have to pay a certain sum, which need not be a large one. Out of this a certain percentage would have to be paid to the secretary besides a weekly wage

Owners could be invited to pay a certain sum yearly, for which they would be supplied with reliable drivers.

This is only a rough sketch on what lines a society of motor-car drivers could be conducted, and I should be pleased if any of your correspondents, as also owners, would give their opinion on the subject.—Yours truly,

A. C. M.

To the Editor of *The Motor-Car Journal.*

Sir,—Will you allow me space in your paper to answer the remarks hurled at the certificated driver? I am one of them, and have read with interest the letters of past weeks. I paid £15 15s. for a full course of lessons and made it my one study. I am confident that, given a fair trial, I could keep a car clean and in good running order, and do most of the repairs. I think it very unfair on the part of professionals to tread on the learner, but the reason is, no doubt, that they have cut the price down. I have been trying for months past to get a situation as driver, but have failed. If there is no chance of a certificated driver getting a start, why cannot something be done to stop firms from taking from the intended drivers their hard-earned savings?—Yours truly,

Certificated.

To the Editor of *The Motor-Car Journal.*

Sir,—Seeing recent letters *re* "scarcity of good driver mechanics," I thought I would offer my services to owners, so answered some of the advertisements. I got no reply from the majority, others replied in two or three weeks offering me the situation to take charge of car, help in the garden and house, at 25s. per week. Now, as I have had over seven years' practical experience with motors and am offered a situation in one of the biggest works in the country, at present holding the position of head mechanic to a firm of builders, I think the princely sum of 25s. per week to be a combined driver-mechanic, gardener and house assistant is to be ignored. I might add that I offered my services as driver mechanic in the interest generally of the motor manufacturers, as it appears to me that cars are getting a bad name owing to owners employing bad mechanics.—Yours truly,

B. D.

To the Editor of *The Motor-Car Journal.*

Sir,—There are many workmen as well as myself who would like a berth in private service; of course, these men would want first-class wages, and, like myself, would like a valuable car to look after. If motor-mechanics were put in the care of valuable horses, what would be the result? and it is the same with motors. I think if all owners of motors would only think what a motor-car is they would come to the point—every man to his trade. If owners want their cars always in readiness they must employ skilled labour, and by so doing they would be at a much less expense at the end of the season; their cars would be in a good condition instead of having to be sent to the works for a complete overhaul, which would cost almost as much as a new car.—Yours truly,

Piston.

The Motor Union.—B. G. B. (Oldham), who asks for the address of the Motor Union, is referred to 119, Piccadilly, W.

Expert's Fees.—F. R asks what is the fee of an expert for examining and reporting upon a motor-car?

Steam Cars.—Mr. F. Wilkinson writes:—"I notice in your issue of the 26th ult. a letter, signed 'Northern Steamer,' asking for information about the Stanley steam car. If the gentleman will send his address to me at Prince's Chambers, John Dalton Street, Manchester, I shall be pleased to give him my experience with the car."

The Eisemann Magneto High-tension Ignition.—"Philo" writes:—"Will any motorist who is using the Eisemann magneto ignition on his car send his experiences of the same?"

CLUBS AND ASSOCIATIONS.

LEICESTERSHIRE.

A NEAT programme of fixtures and book of rules has been issued by the Leicestershire Automobile Club. Among the places to be visited by the club are Ashby-de-la-Zouch, Rugby, Oakham, Stratford-on-Avon, Matlock, Lichfield, and Derby. A garden party will be held at Ashbourne on July 9th.

AUSTRALIA.

OUR Melbourne correspondent writes:—"After several weeks of careful work by the provisional committee of gentlemen appointed to frame rules and bye-laws, prepare initiatory work, select officers, &c., the 'Automobile Club of Victoria' is now fairly started upon what seems to portend a successful career. The provisional committee consisted of Messrs. Harry Maddox (chairman), H. B. James (hon. secretary), Drs. Merrill and Officer, and Messrs. T. Rand, S. Stott, H. Sutton, H. Bagot, S. Joshua, and S. Day. The club held its inaugural run from Melbourne to Aspendale Park (18 miles) on February 20th. The officers appointed for the first year of the club's existence are:—President, Sir John Madden (Lieut.-Governor and Chief Justice); vice-presidents, Drs. A. P. Merrill, Messrs. W. Howard Smith, and Thos. Rand; hon. treasurer, Sydney Stott; hon. secretary (acting), H. B. James; and committee, Drs. Officer and Ryan, and Messrs. H. C. Bagot, Harry J. J. Maddox, H. Rose, Syd. Day, J. R. Crooke, J. Craven, and J. Moffat. Club premises in Collins Street, Melbourne, have already been secured, and will possibly be occupied in a few days. The membership is already about 120. Mr. W. Thompson, of Adelaide, South Australia, is an enthusiastic motorist, and was present at a meeting of the newly-formed A. C. of V. in Melbourne the other evening, receiving a warm greeting. At the previous meeting, Mr. Will Reid, of Sydney (member A. C. of A.) was present, and gave the members present a résumé of his club's works and progress."

NOTTINGHAMSHIRE.

IT is the intention of the Nottingham Automobile Club to hold their second hill-climb of the season on Saturday, May 14th. The climb will be in two classes: Firstly, for standard touring cars the property of club members, which must carry their full complement of passengers; secondly, for cars of any type or seating capacity either the property of club members or friends, such friends to be introduced by two members of the Club. The winner of the first event will be for the most meritorious performance, and of the second, the one doing the fastest time. The winners in each section to receive the Club medal (not badge). Further particulars may be had on application to the Club secretaries, Messrs. W. D. Wells and R. Harbidge, St. Peter's Hotel, Nottingham.

NORFOLK.

THE Norfolk Automobile and Launch Club held their opening meet of the season at Cromer on Monday, when about sixty members sat down to luncheon at the Grand Hotel. The chairman of the Club, Mr. G. M. Chamberlin, was unavoidably prevented from being present, and Baron de Barreto (vice-president) took the chair. The following toasts were given after lunch:—"The King." "Success to the N.A. and L.C." Mr. Clark, the vice-chairman of the Club, said that the N.A. and L.C. was in a very sound position. They numbered 114 members, and at the next committee they hoped to increase the numbers. Already the Motor Union (of London) had helped one member of their Club in a legal case, and they were always willing to support a good case for the help of affiliated members. The Chairman responded to the toast, and wished the Club every success. The following ladies and gentlemen were present:—Baron and Baroness de Barreto, Mr. Sidney Wolton, Mrs. de Maucha, Mr. and Mrs. H. L. Clark, Mr. H. Williams, Mr. H. W. Egerton, Mr. W. P. Cubitt, Mr. and Mrs. W. W. R. Spelman, Mr. and the Misses Boardman, Mr. and Mrs. Bradley, Mr. and Mrs. Wigg, Mr. King, Major and Miss White, Mr. and Mrs. Maudsley Brooke, Mr. and Mrs. Wickham, Mr. and Mrs. J. W. Brooke, Mr. J. M. R. Ray and Mr. J. N. C. Ray, Mr. and Mrs. C. H. A. Lock, Mr. P. Norgate, Mr. G. W. Base, Mr. and Mrs. C. de F. Clarke, Mr. and Mrs. H. Chamberlin, Mr. Estcourt, Mr. J. Griffin and Miss Griffin, Mr. A. E. Lark, and Mr. J. W. Howlett.

CASES DISMISSED.

THE adjourned summons against Captain David Morgan, J.P., member of Brecon County Council, of Bank House, Brecon, for driving a motor-car along Kensington Road, on February 14th, at a speed exceeding twenty miles an hour, came on for hearing before Mr. Lane, K.C., at the West London Police Court just before the holidays.

This was the case in which Mr. Staplee Firth, for the defence, disputed the accuracy of the police stop-watches, and at his suggestion a test of the watches was made in court, when only one second's difference was discovered between them, the magistrate observing that the test told greatly in favour of the police evidence.

At the conclusion of the last hearing Mr. Lane suggested that it would be advisable to secure the services of an expert to test the car, as the defendant averred that it was not capable of going at the speed complained of—viz., twenty-five miles an hour—on that particular day, as the speed gear was out of order, and his worship then added that if the defendant's evidence was correct, it amounted practically to an allegation of perjury against the police.

Evidence was given by the defendant's driver to the effect that on the day in question the lever, through a defect, could not reach the highest—the fourth—notch, but only the third.

Lieut.-Colonel Crompton, R.E., stated that on the 17th inst. he made a test of the defendant's car over a measured distance of 220 yards, and found that with the lever at the third notch the car could only go at the rate of 17·06 miles an hour.

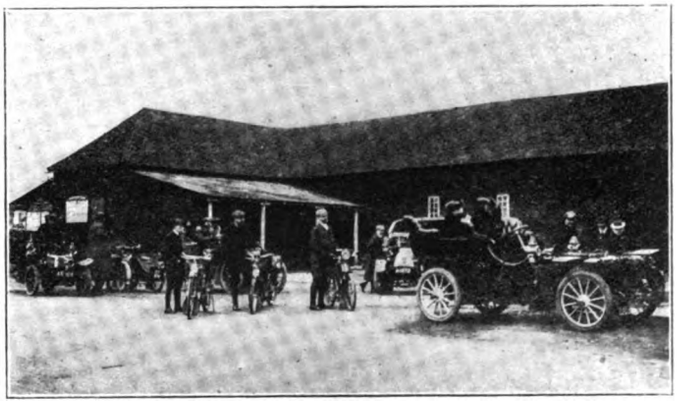
The Magistrate: As regards stop-watches, have you found it requires a great deal of training to overcome tendencies to error in stop watches?

The Witness: Yes, and the difficulty increases with the inferior quality of watches.

Mr. Firth: I believe a man with a stop watch can retard the watch for 20 seconds or 80?—Yes.

The Magistrate: By accident or design?

The Witness: Easily by accident in the hands of an unskilled operator.



Lewis John Reeves stated that on February 16th (two days after the car was stopped) he was sent to repair the defendant's car, which was a Wolseley. He found that the lever was bent and could not reach the fourth notch.

The magistrate observed that after that evidence the whole point centred on the stop-watches. It was very necessary that the question of the reliability of stop-watches used by the police should be settled.

The magistrate inquired if the watches could be scientifically tested, and Colonel Crompton thereupon took them in his hand and tested them, with the result that they did not differ one-fifth of a second in 28 seconds.

Mr. Lane, in giving his decision, said it lay on the prosecution to prove their case beyond all reasonable doubt, and he was not satisfied that that had been done here. He therefore dismissed the summons, but he had no reason to doubt the good faith of everyone concerned in the case.

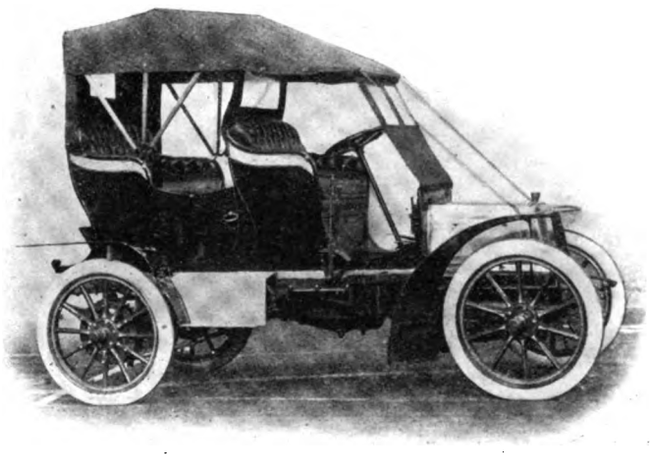
MR. BERNARD REDWOOD, of 81, Shaftesbury Avenue, W.C., was summoned at the South-West London Police Court for motoring along Portsmouth Road, Putney Heath, at a speed exceeding twenty miles an hour. Police-constable 62 V.R. deposed that on March 15th he was stationed in

The Inaugural Run of the Hertfordshire Automobile Club. Some of members at the Red Lion, Hatfield.

Portsmouth Road with a tape and a stop-watch, provided by the Police Commissioner to test the speed of motor-cars. At a distance of 220 yards stood Police-constable 341 V., and at a signal from him witness timed defendant's car, which covered the 220 yards in fifteen seconds, giving a speed of thirty miles an hour. Mr. Redwood, who was driving a Brooke car, Mr. T. W. Barber, and others gave evidence, and after Mr. Staplee Firth had been heard the magistrate dismissed the summons, but refused costs.

JOHN DEVON, of Romford Road, East Ham, was summoned at Guildford for driving a motor car recklessly, at Ripley, on March 13th. Mr. Chandler (barrister) appeared for the defence, and said that Devon was not on the car, but had lent his licence to a man named Hutchinson, who was in Court, and who was in charge of the car at the time. Sergeant Jarrett said defendant was not the man in charge of the car at the time. Devon was, however, in the car. The summons was amended, and Arthur Hutchinson was called upon to answer it jointly with Devon. Sergeant Jarrett said at 9.30 p.m. on the day in question he was on the Ripley road, and saw a car approaching from the direction of Guildford. Immediately it passed him it first ran on the off-side, and then on the near side of the road on to the footpath, a portion of which was torn up. He next heard two loud reports, and the car ran direct across the road to the other side. He saw the broadside of the car three times, and the man appeared to lose control after passing him. Hutchinson was the driver, and he said to him, "There is something the matter either with you or the car. You had better get out and see." He produced a licence with the name, "John Devon, 682." Witness refused to allow Arthur Hutchinson to drive the car home. Mr. Chandler: Will you swear Devon was in the car? To the best of my belief he was. Mr. Chandler requested Hutchinson's brother to stand up, and asked witness if he would swear he was not in the car at the time? Sergeant Jarrett: I won't swear to either of those men; but Arthur Hutchinson was there certainly. Mr. Chandler said Devon's defence was that he was not there, and, with respect to Hutchinson,

Digitized by Google



he placed him in the witness-box. He declared that on the journey from Guildford one tyre punctured, and this caused the tyre on the other back wheel to come off, and made the car sway. He stopped it as quickly as he could. William Hutchinson, 32, Great Peter Street, Westminster, brother of the last witness, said he was not in the car at the time, and Devon was not there. He corroborated the statements of the last witness, and said the reports the sergeant heard were from the exhaust box and not the tyres at all. Sergeant Jarrett: After hearing this man's voice I recognise him as being the other man in the car. The Chairman said the Bench would dismiss the summons on the ground that it might possibly have been an accident.

THE ACT OF 1878.

A CASE was heard at the Marylebone Police Court before Mr. Curtis Bennett, on the 31st ult., the Motor Transport Company having been summoned under the Act of 1878 for not consuming, as far as possible, their own smoke. The alleged offence took place on the 24th February last. The prosecution was conducted by the London County Council, and the case was defended by Mr. Staplee Firth on behalf of the Motor Van and Wagon Users' Association. Mr. Curtis Bennett ultimately found that the vehicle in question was a light locomotive under the Act of 1896 and was exempt, and that the Act of 1878 did not apply, and he therefore dismissed the summons.

IGNORING THE REGULATIONS.

AT North London, Stanley Redpath, of Norwood Road, Tulse Hill, was summoned for unlawfully acting as the driver of an unregistered motor-car at Seven Sisters Road at 11.20 a.m. on March 3rd. There was a second summons charging him with fraudulently using a mark for the identification of his car, which had not been authorised. The defendant admitted the offences, but said that he was under the impression that his

Messrs. C. S. Rolls & Co.'s 15-h.p. Panhard Side-entrance Double Phaeton with Cape Cart Hood and Storm Apron. (See page 78, issue of March 26.)

licence to drive a car covered everything. He had printed his licence number on a piece of white cardboard, and attached it to his car. Mr. d'Eyncourt pointed out that the regulations required that the registered number of the car should be in white letters on a black ground. The policeman who stopped the defendant said his attention was attracted by the high number and the fact that the plate was on cardboard. The defendant said he got his licence on the 25th, and after he had been stopped he applied to the County Council for the registration of the car. Constable 604 W said that on the 9th he stopped the defendant at Streatham in similar circumstances, and he was fined at the South-Western Police Court. Mr. d'Eyncourt imposed fines of 10s. and 2s. costs on each summons.

NO APPEAL AGAINST FACT.

AT Andover County Bench the magistrates refused leave to a motorist to appeal against their decision on the ground that the case was decided on a question of fact and not of law.

COMMITTED FOR TRIAL.

AT Westminster, Robert Forsyth has surrendered to his bail, before Mr. Horace Smith, to answer an adjourned summons at the instance of the police for driving a motor-van at King's Road, Chelsea, to the common danger of passengers. Mr. Stephen Lynch was counsel for the defence.

On the evening of the 22nd of December last the defendant was driving a covered motor-van for Harrod's Stores, Limited, when in a narrow bend of the road it was said that he lost control of the machine in avoiding an omnibus, and ran up on to the pavement. Mrs. Ryder was knocked down and so seriously injured that she had to remain in St. George's Hospital for about three months. The pace the defendant was driving at was given as seven miles an hour. Police-constable 53 BR. said the road was greasy, and he saw the car skid. Both wheels of the car went on the pavement and pinned the woman against a wall. Mr. Lynch, for the defendant, said there was no negligence on his part. His car skidded after he had negotiated the corner carefully. Mr. Horace Smith said it was essentially a case for a jury, and sent it for trial. There was no allegation of impropriety on the part of the driver, who was released on bail.

AUTOMOBILE ACCIDENTS.

TURNING out of the Old Steine at Brighton along the Front, a motor-car belonging to Mr. W. Woodhams, of Surbiton, encountered an automobile let on hire which was coming along. Fortunately no one was injured, although both vehicles were damaged.

ON Sunday a motor-car descending the Grove Hill at Harrow turned a somersault, hurling its occupants from their seats and inflicting severe injury upon Mr. Lambert Hall, the owner of the car, and his family, who were being driven by Alfred Bird. The driver was also hurt.

A MOTOR-CAR, driven by A. W. Clifford, dashed into a wagonette on the road between Rye and Hastings on Sunday. The party on the wagonette sustained great injuries in the collision.

CLAIM AND COUNTER-CLAIM.

IN the City of London Court, Mr. H. F. Joel sued Mr. Louis Sinclair, M.P., for £46 6s. 6d. for repairing a motor-car. The plaintiff said that the defendant's car, after being worked very heavily by him, was brought to be repaired. Numerous things were required to be done, and it was agreed that the expenses should not exceed £50. Mr. Sinclair, M.P., said that he had paid over £600 for the car in May last, and after having it for a few months he found a few repairs were necessary. The car was sent to the plaintiff's, who, however, returned it in such a condition that it was useless. While objecting to pay the plaintiff's claim, he counter-claimed for £120 for the plaintiff's defective work, and for damage which the plaintiff's men did to the car in an accident on the way to Hampstead. Judge Rentoul, K.C., found for the plaintiff for £39 1s. 6d. on the claim, and for the defendant on the counter-claim for £15.

MOTOR-CAR v. HORSE-DRAWN CART.

AT the Windsor County Court an action was brought by Mr. Charles Franklin Torrey, of Westminster, against Mr. Thomas Tilly, hay binder, of Colnbrook, to recover the sum of £18 8s. for damages done to plaintiff's motor-car through being run into by defendant's cart on the road between Iver and Langley station, on August 29th last. His Honour gave judgment for plaintiff for £16 10s. 1d. and costs and dismissed the counter-claim with costs.

A QUESTION OF WARRANTY.

IN the King's Bench Division the case of Ogilvie v. Dew has been heard, in which plaintiff claimed damages for breach of warranty of a Gardner-Serpollet motor-car which he bought from the defendants, who carry on business at Reading, in June, 1901, for £450. In the result the jury, after a lengthy retirement, found for the defendants on the plaintiff's claim for breach of warranty, and also for the defendants on the counter-claim for work done, etc., for £59 3s. 7d.

CONVICTIONS AGAINST MOTORISTS.

Hull	No number	10s., etc.
Highgate	No light on motor-cycle	1s., etc.
Lurgan	No lamp	40s., etc.*
Alfreton	Negligent driving	Warrant issued.
Croydon	No licence	5s. 6d.
,,	Employing unlicensed driver	5s. 6d.
Caledon	No lamp	40s.*
Portadown	No light	40s.
Sutton Coldfield	Furious driving	£5.
Westminster	No light	3s., etc.
Dorchester	Dangerous speed	5s., etc.
,,	Car not stopping	10s., etc.
York	No number plate	2s. 6d., etc.
Woolwich	Not producing licence	20s., etc.
Oxford	Allowing a car to stand 30 minutes on roadway	1s. 6d., etc.
Manchester	Driving dangerously	21s., etc.
Buckingham	Unattended car	10s., etc.
Newbury	Driving dangerously	20s., etc.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, APRIL 16, 1904. [No. 267.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ENFIELD is a pleasant place in the northern district of the Metropolis, but it is apparently a centre of danger for motorists, three of whom have made an appearance in one day at the local police court. The police have a well-devised trap extending over a length of 352 yards, and the magistrate, who is also a member of the Middlesex County Council, said he felt a speed limit of much less than twenty miles per hour should have been imposed. Surely Enfield is not seeking to become as notorious as was Reigate in the old days. Our illustration, designed by Mr. Alfred Dunhill, represents the sort of thing to which motorists are being subjected in many places.

◆ ◆ ◆

A Conviction Defeated.

AGAINST the decision of the Beaconsfield magistrates Mr. I. A. Trueman has successfully appealed to the Buckinghamshire Quarter Sessions. He was fined £2 and costs for driving a motor-car to the common danger at Chalfont St. Peter on the 3rd ult., and the bench, having regard to some of the evidence, decided on conviction. On re-hearing the case at Quarter Sessions the majority of the magistrates were of opinion that this could not be sustained. Such a result should encourage others not to accept adverse verdicts with resignation.

◆ ◆ ◆

The Rule of the Road.

THE Lord Chief Justice Clerk of Scotland (the Right Hon. J. H. A. Macdonald), whose letter in our Correspondence in reply to Colonel Magrath raises an important question, has won distinction in many spheres, ranging from the law to volunteering. He is an enthusiastic motorist, and, in view of the opening of the touring season of 1904, we hope the points these two gentlemen have brought forward will be discussed both at meetings of the provincial clubs and in our columns. Nothing but good can result from such an expression of opinion.

◆ ◆ ◆

Motor Volunteer Corps.

THE corps had an exceptionally busy time during March. A staff ride was held under Lieut.-General Sir John French, commanding the 1st Army Corps, when some sixty officers were conveyed over the whole of the district of Chichester. At the conclusion of the tour General Sir John French expressed to the commanding officer his entire satisfaction with the arrangements which had been made. A most interesting Staff tour was carried out under Lieut.-General Lord Grenfell, commanding the 4th Army Corps, on the 24th and 25th ultimo, when about eighty officers of the Scottish Volunteer Brigade were conducted around the London defences. From the 17th to 22nd March Messrs. J. Whittaker and J. McKelvie were employed under General Sir Leslie Rundle, K.C.B., on a Staff ride at York. This was the first occasion on which the corps has been called upon for duty in the North of England, and it is gratifying to know that General Rundle has expressed his appreciation of the services rendered. From the 27th to 31st March Captain J. E. Hammond and Member F. Lanchester were also employed under General Rundle at York. During the Volunteer Cyclist manœuvres held in the neighbourhood of Chester during Eastertide, from 1st to 4th April, Captain J. F. Hammond and Mr. T. W. Kemp were on duty with the Umpire Staff.

◆ ◆ ◆

Motor-car Imports and Exports.

ALTOGETHER only 492 foreign motor-cars were imported into this country during last month, their value being returned at £169,166. "Parts" were responsible for £20,741, bringing up the total imports for March to £189,907, as against £206,995 in the preceding month, and £206,296 in March, 1903. So far this year, that is to say for the first three months, the imports stand at £517,674, or roundly £50,000 more than in the same period of last year. We are glad, however, to be able to record an upward move in the exports of British automobile productions. Thus last month fifty-five vehicles were shipped, these with the "parts" being valued at £29,285. For the three months ending with March the exports are returned at £86,116, £24,000 more than in the corresponding three months of 1903.

◆ ◆ ◆

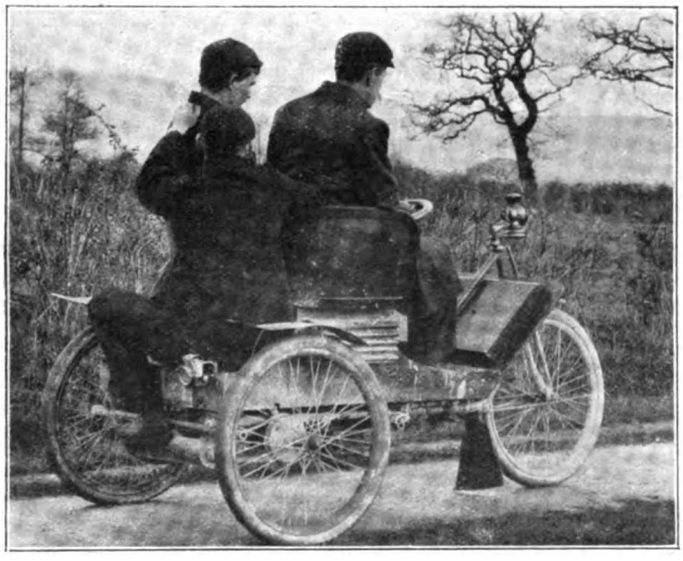
Registered Cars.

ACCORDING to Mr. Lane, K.C., the magistrate at the West London police court, care must be taken by repairers of motor-cars to distinguish between the use of cars by "intending purchasers," and those sent "for repair." The words "intending purchaser" in the Act mean exactly what they say, and cannot be extended to cases of cars for repair—an example of accurate representation of meaning not always associated with legal diction. The instance which drew attention to this distinction is reported in our list of "cases dismissed."

◆ ◆ ◆

1,200 Signposts for Somerset.

AT the last meeting of the Somerset County Council Mr. McMurtrie brought forward the report of the Motor-Car Committee, which stated:—The various provisions of the Act, as to the granting of licences and registering motor-cars, the keeping of registers, and granting identification marks and numbers, have been satisfactorily carried into operation. The number of registrations entered and licences granted to the present date are:—Motor-cars, 169; motor-cycles, 207; drivers' licences, 453; manufacturers' identification marks, 5. The committee recommended the Council that in view of the opinions of the Local Government Board, and of the vagueness and indefiniteness of the recommendations of a large proportion of the District Councils, no application should at present be made for regulations restricting the use or speed of motor-cars under the provisions of Sections 8 and 9 of the Act, as they are strongly of opinion that it would be advisable that the provisions of Section 1 of the Act should have a fair trial before other re-



Digitized by Google

strictions are made, either with regard to the use of motor-cars on certain roads or as to the speed at which motor-cars may be driven. On the whole the committee estimate that at least 1,200 danger notices will be required, which, at £2 each, will cost the county £2,400. They recommended the Council to authorise them to confer with the several District Councils on this part of the subject.

◆ ◆ ◆

Petrol for Patrols.

OFTEN have we pointed out that the motor-car, instead of being regarded by the police as something to obstruct whenever possible, should be looked upon by them as rather a friend. The accompanying illustration shows its use in this connection. A policeman in the West of England, having arrested a prisoner recently, was able to take advantage of an Avon Trimobile in marching his prisoner to the station. Now that the Chief Constable of East Sussex has a motor-car, and several demonstrations of its value in police work similar to that illustrated have been made known, it is not to be wondered at

that there are folks bold enough to advocate the substitution of the mounted patrol by the petrol-mounted policeman. Since writing the foregoing a member of the Metropolitan police force has found the motor-car equally serviceable in effecting the capture of an alleged coiner.

◆ ◆ ◆

Climbing a Mountain.

BEFORE the Manchester Automobile Club, Mr. G. Higginbotham has been giving some of his experiences with his 60-h.p. Mercedes. Included in these was the first really authentic account of how he climbed the Great Orme's Head. What led him to attempt this was, while staying at the Grand Hotel the porter informed him that a gentleman had recently got to the top with his car. Having seen this machine at the door several times, Mr. Higginbotham and his friends decided to inspect the route, without, however, the slightest intention of attempting it. Accordingly they got on board the tram and went up to the top. On the way up the conductor of the tram told us that the Panhard car had got stuck each time a little above the crossing called the Black Horse Gate, and had never really got to the first station, let alone the top, although he had been trying for four days, and, added the conductor, he did not believe that there was a motor-car made that could do it. So the motorist said that he would get to the top if any car could. After walking down from the top over the fields they eventually decided on a route, and started to have a trial trip up to the first station next day before lunch, intending to come back, and after lunch to tackle the job in earnest. They took two mechanics armed with spades, Mr. Higginbotham, Mr. Williamson and Mr. Ward, all on the car. Starting just below the tram she simply flew up the steep portion which the tram follows up to the crossing at the Black Horse Gate, and so fast did they go that the people in the houses, who came out to see them coming, did not see them at all till they came down. They reached the first station four minutes after leaving the bottom, the steepest gradient being 1 in 3. But they did not stop, going on over great pieces of broken rock, called a road, towards St. Tudno's Church, about half-way to which they took the grass, but it had commenced to rain and made the grass so slippery that after a time the wheels spun round and dug great ruts. So they got some rope and wound it round the back tyres. This helped, and eventually, after crossing the line, they got on some stony ground and reached the flagstaff, actually touching it. The return journey was a very simple matter, as the car had three good metal brakes, water-cooled, and with seven men and a dog they reached the bottom one hour after their start. This was probably the first attempt to climb a mountain in this country which was successfully accomplished.

◆ ◆ ◆

The Speed Limit at Dover.

ALTHOUGH Sir Woollaston Knocker, the Town Clerk of Dover, declared that the speed limit the local Corporation have sought to impose upon motorists will only mean a delay of nine minutes in passing through the borough, no real evidence in support of the application was tendered to Mr. G. P. Burd, who conducted the inquiry on behalf of the Local Government Board. On the other hand, Lieut.-Colonel Holden, the chairman of the A.C.G.B.I., expressed the view that the proposed ten mile limit would not give the safeguard the public demanded. After all, the speed must be limited by the traffic at the time, the condition of the road, and the common sense of the driver, rather than by any arbitrary enactment—a view which was supported by Mr. W. R. Jeffreys, who said that hansoms in London attained a speed of from twelve to fourteen miles an hour, and omnibuses twelve miles for a time. Then, on behalf of the Automobile Club, Mr. G. W. Ricketts gave the legal opinion, and contended that, as the ordinary law was very stringent, this section of the Motor Car Act ought not to be lightly put into force on the application of the local authorities.

◆ ◆ ◆

The Evolution of Speed.

IN our correspondence columns, Mr. E. Kennard, J.P., whose motoring enthusiasm continues to advance with every development of the motor-car, draws attention to the desire for increased power evinced by most motorists. He warns intending motorists not to begin their career on the car with vehicles of too low a power, and gives his own experience as a specimen of the way the wish for more and more power develops. While we agree with Mr. Kennard as to the whetting of the appetite in an Oliver Twist direction, it is to be hoped that his advice will not discourage prospective buyers whose resources will not allow them to go beyond the small car.

◆ ◆ ◆

Commerce and Pleasure.

NOT often do Chambers of Commerce enjoy the company of sportsmen at their annual assemblies, but such a pleasure was given the members at the Isle of Man Chamber of Commerce at their annual dinner last week. Mr. J. W. Corlett presided and proposed the toast of the King, making kindly reference to the governor of the island, Lord Raglan, who thanked those present for their appreciation. As the Legislature of Mona was one of the oldest in the world, it had shown it was like old wine, it improved with age. Their recent record passing of the Motor Bill might well cause other nations to look on with envy to see a Bill pass the three readings by both

Digitized by Google

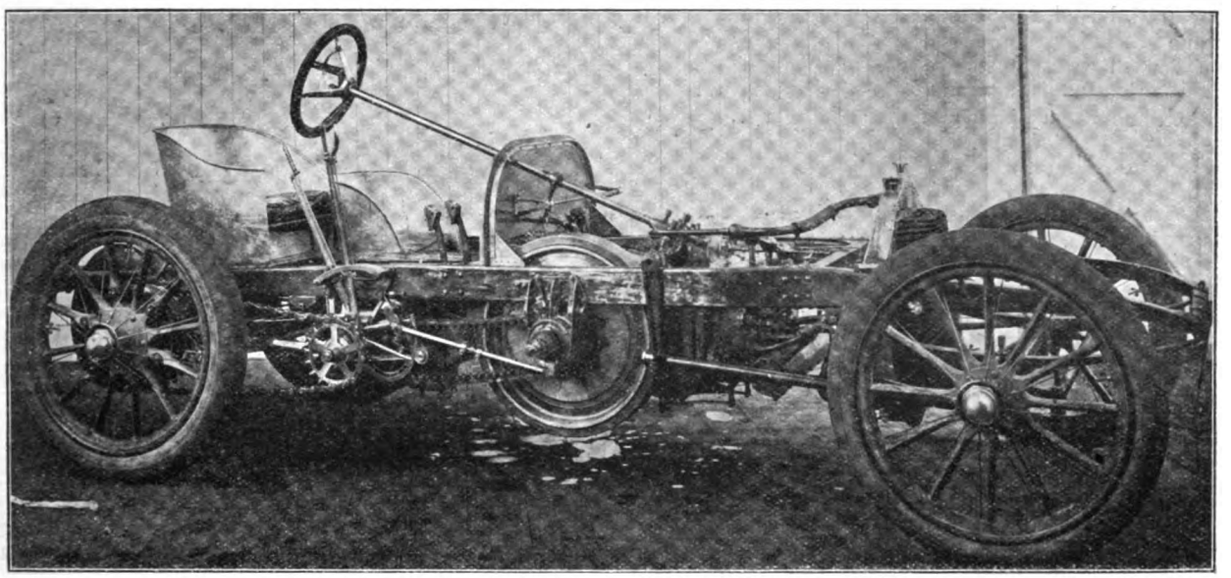
branches of the Legislature in one day. He was pleased to state that he had received the Royal Assent to the Bill. They might fairly flatter themselves at their execution, with such facility and dispatch, of so important a measure for the Island. Mr. J. W. Orde, secretary of the A.C.G.B.I., and Mr. Alfred Bird, who also represented the Automobile Club, were among the speakers, the former remarking that their visit last year to Ireland was worth £60,000 to that island, but he could not say how much it would bring to the Isle of Man. The two days at Southport took 30,000 people there the first day, and 50,000 the next day. They had fixed May 10th for the race as a convenient time, midway between the Easter and Whitsuntide holidays. There were no roads better suited to their purpose in England or Ireland than those in the Isle. He could not but take that opportunity to thank His Excellency, the Deemster, and Col. Freeth for the many excellent suggestions they had given him, which had advantageously altered the plans he originally had in mind.

◆ ◆ ◆

A Candidate on Motoring.

AWAY in Devonshire several Parliamentary candidates have been touring among the villages in motor-cars, and at the inaugural meeting of the South Lincolnshire Club, referred to on another page, Mr. E. M. Pollock, a prospective candidate for the Spalding division of Lincolnshire, has been advocating automobilism. He said that an old friend of many persons in Spalding and an old friend of many in the district was one of the first men to tear up the old red flag, and thereby, under the Act of 1894, allowed motor traffic upon the high road. He referred to the late Lord Winchilsea. At a gathering held in London, in order to demonstrate the utility of motor-cars, he tore up the last remnant of the red flag in order to show that henceforward there might be motor-traffic on the highway. They had all enjoyed their ride that afternoon, and such would no doubt give a great impetus to the improvement of motor-cars, because it proved how they could be used successfully by persons, not only in their business, but also for pleasure.

◆ ◆ ◆



The Law's Inconsistency.

AN inconsistency in the Motor Car Act of last year has just been exposed by a police magistrate, and we trust the point will not be forgotten by automobilists who are watching the operation of the present law, in view of its temporary character. At the South West London Police Court, a motorist has been summoned for driving by night without carrying a proper light, illuminating his rear identification plate. Having been fined, he asked that the conviction might not be recorded on his licence. Mr. Francis, the magistrate, replied that while it was left to his discretion in a case of excessive speed he had no alternative to endorsing the license in this case. There can be no doubt that the latter instance was of less importance than furious driving and yet the sentence is practically heavier. That the magistrate has no discretionary power in such circumstances is one of the absurdities of the Act that was certain to be revealed sooner or later.

◆ ◆ ◆

The Wolseley 96-h.p. Gordon Bennett Racer.

WE are this week able to give two illustrations of the 96-h.p. racing car which has been built by the Wolseley Company for the British eliminating trials in connection with the Gordon Bennett contest. The main dimensions are:—Wheel base, 9 ft., track, 4 ft. 7 in.; rear wheels, 36 in. diameter and 5 in. tyres; front wheels 34 in. diameter and 3½ in. tyres. The motor has four cylinders of the horizontal type; it is suspended in the frame in such a position that the *mecanicien* may be able to make adjustments whilst travelling. It is fed by an equalising carburettor of special design, one jet supplying the four cylinders. The flywheel is of extra large diameter and the motor can be very rapidly accelerated up to 1,300 revolutions per minute. The pump is carried on the radiator and driven from the motor by a telescopic shaft with spring drive. The gear box is suspended from three points, the shafts running on ball bearings. Both front and back axles are of I section steel, and the wheels are of the artillery type reinforced with wire spokes to take the side strains. The petrol and oil supplies and pressure gauges are all placed so that the *mecanicien* has them constantly under observation, the commutator especially being placed so that it can be got at without trouble. Both foot and hand brakes act on the back wheels, the foot brakes being of the Wolseley special internal expansion type, the hand brake operating bands working on drums which are part of the chain wheel castings. The top speed of the car is equal to 75 miles an hour, with the engine running at normal speed; but, as previously mentioned, it can be accelerated up to 1,300 revolutions per minute. The sparking plugs have been specially made and are extra large; the coil is provided with two tremblers, only one of which works at a time, a cross-over switch being provided so that either may be used. A separate switch is fitted to each low tension lead to act as a detector to the different plugs.

The Wolseley 96-h.p. Gordon Bennett Racer—Right-hand Side.

Joint Runs.

THE idea of combined meets of provincial clubs, to which we made reference last week in noticing the proposed gathering of northern clubs at Buxton, has caught on, and we are glad to record that such an event took place on Saturday last at Ashby-de-la-Zouch, a pleasant place with an uncomfortably long name. The Leicestershire, Nottingham, and Derbyshire automobile clubs gathered together, and, although the weather was cheerless, about fifty automobiles arrived at the Royal Hotel, which was made the joint headquarters for the day. Such runs are conducive to the best interests of motoring, and will have a good effect on hotel proprietors likewise.

◆ ◆ ◆

Rural Motor Services.

GENERAL interest has been expressed recently in Farnham and Haslemere as to a suggested motor-omnibus service between the two towns, and an advocate of the proposal who stood for the Farnham Urban Council has just been returned second highest on the poll among a long list of candidates. Some of the large rural landlords also favour the idea, as an improved communication with railway stations is a pressing need in the many villages of the locality, and a good passenger and parcels traffic is assured. The Great Western Railway Company has only recently inaugurated these motor-car services in various parts of Cornwall, but already the directors have found them of material value in feeding the line with traffic and have ordered the construction of additional cars, and many local residents are hoping that the time is not far distant when the directors will be able to announce a similar enterprise in Surrey.

◆ ◆ ◆

Letters of Identification.

A FEW months ago we gave the letters of identification for the various counties and boroughs of the United Kingdom. This week we republish a list of the marks relating to Scotland, and in later issues those for other parts of the United Kingdom will be given. There is a good deal of interest taken by the ordinary public in the marks of identification, and motorists are frequently asked by their friends as to where passing cars have come from. Hence the value of having the marks of identification readily available.

◆ ◆ ◆

Club Events.

POSTPONEMENTS are the order of the day. The date of the side-slip trials has been altered to May 7th, the thousand miles preliminary run beginning on Monday from the Locomobile Garage, South Kensington. The trials of light delivery vans which were to have taken place in October have been put off till February of next year, thus steering clear of the Reliability Trials in November. Another event in which great interest is likely to be taken is the parade of heavy motor-cars on the Thames Embankment on the 30th inst. The first vehicle will be located about fifty yards east of Charing Cross Bridge, and will move off along Victoria Street to Grosvenor Place, the procession dispersing at Hyde Park gate.

◆ ◆ ◆

A Horse with a "Peculiar Habit."

A GENTLEMAN who lives at Palace-knowe, in the unfamiliar town of Beattock, which is situated in Dumfries, has a horse which, to quote his letter just received, "has a peculiar habit of wheeling right in front of a motor-car when it comes almost opposite a motor." Our correspondent knows of several more equines in the district similarly unmannerly, and therefore asks us to invite motorists to slow down when seeing horses in that locality. It may happen that they may meet this particular animal with the "peculiar habit," in which case they would find an obstruction on the roadway which might prove a bit cantankerous. Whilst giving our correspondent every credit for good intentions, we would like to point out that the sooner he gets rid of a horse of such antiquated notions the better it will be for himself as well as for others. An animal that cannot behave itself properly when meeting a motor-car ought to be transported, say, to Antwerp.

◆ ◆ ◆

Motorists as Public Benefactors.

THE public has been so accustomed to see motorists as defendants in legal cases that it may be as well to point out, says the "Law Times," that during the last twelve months certain automobile organisations have been active as plaintiffs, with the result of illustrating the homely saying that "what is sauce for the goose is sauce for the gander." The ordinary user of the roads, whether on foot or on horseback, on cycle or in carriage, will have largely to thank the motorist for bringing about a more wholesome regard for the public safety in the matter of unlighted vehicles left in obstructing positions, projecting and invisible loads, and gross negligence on the part of local authorities. It is a somewhat absurd anomaly that the fastest vehicles on the road should be the only ones compelled to show a red rear light. A succession of cases has also revealed the fact that, whatever may or may not have been the speed at which a motor was being driven, the stop-watch appliances served out to the police were far from being accurate.

◆ ◆ ◆

The British Racers.

TO-DAY (Saturday) the weighing-in of the cars entered by British firms for the eliminating tests of the Gordon Bennett race will take place. The drivers of the Wolseley cars in the Isle of Man contest will be Messrs. Charles Jarrott, Campbell Muir, and Sidney Girling. Of the five Napiers entered the drivers will be Messrs. Mark Mayhew, John Hargreaves, J. W. Stocks, Clifford Earpe, and S. F. Edge.

THE Duke of Bedford has ordered a M.M.C. 25-h.p. shooting brake.

AT the Saracen's Head Hotel, Dunstable, Mr. F. R. Hatcher supplies the wants of motorists at all hours of the day and night.

THE Motor and General Tyre Company, Limited, has been registered with a capital of £1,000 to manufacture and deal in pneumatic and other tyres.

DR. BOVERTON REDWOOD has been elected vice-chairman of the Committee of the A.C.G.B.I., and Professor Vernon Boys has been invited to fill his place on the Committee.

THE Automobile Engineering Company, Limited, has been registered with a capital of £15,000 to adopt an agreement with Corders' Trust, Limited, and to carry on the business of manufacturers of and dealers in motor-cars, motors and their accessories, etc.

AT the annual conversazione at the West Ham Technical Institute, one of the attractions of the engineering section was a petrol motor made during the past session by the students, under the direction of Mr. J. Duncan. A display of motor-cycles made by firms resident in West Ham was also on view.

AT a recent meeting of the runs and tours committee of the Automobile Club of America the date and general plan for a spring tour for the Club were agreed upon. The tour will be of eight days' duration, with Gettysburg as the destination, and it will be held from the 26th May to June 3rd. It will include stops at Philadelphia and York, Pa., on the outward trip, and at Philadelphia, Atlantic City and Lakewood, N.J., on the return journey.

THE HIGH-TENSION IGNITION SYSTEM FOR PETROL MOTOR-CARS.

By J. W. Frings.

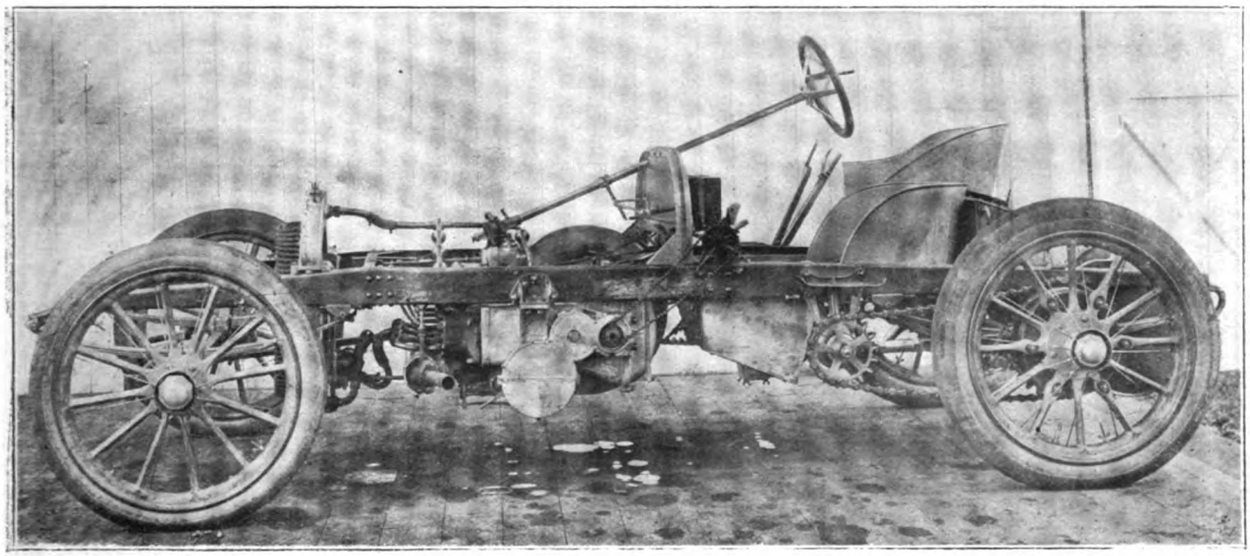
THE high-tension system, as it is popularly called, is that most frequently used for ignition purposes on the motors of self-propelled petrol vehicles, and as a great amount of misconception exists, as well as actual ignorance on the subject, I propose in this article to deal in a non-technical manner with the construction of the various items of apparatus used for this purpose, and to give a brief exposition of the electrical principles involved and their adaptation to their specific uses.

It will be, perhaps, as well to assume an entire lack of electrical knowledge on the part of readers, in order to avoid the possibility of taking for granted that certain facts, necessary for the comprehension of the subject, are known when such might not be the case. I will therefore commence with a few simple electrical definitions.

Electricity.—An invisible agent known only by its effects. The principal electrical phenomena fall under four heads. (1) Statical charges, (2) currents, (3) electro-magnetism, and (4) electric waves. The three latter forms of phenomena are to be observed in the working of the high-tension system.

Currents.—The flow of electricity, which may for example be generated in a battery by chemical decomposition. When zinc is dissolved—in a simple voltaic cell—in dilute sulphuric acid in the presence of a copper plate, the zinc parts with its latent energy as its atoms combine with the acid. This energy is expended in forcing electricity through the acid to the copper plate and back again to the zinc, outside the cell, through the conducting medium—the wiring of the electric circuit. Current is also generated magnetically in a dynamo. As this method enters so little into the constitution of the high-tension system, it is hardly worth while dealing with its phenomena, which will fall more properly in line in a future article dealing with the magneto system of ignition.

Accumulator.—A type of battery in which an extremely active condition—chemically—of certain metals and metallic oxides is artificially created by forcing a current of electricity through them. This decomposes the original paste oxides—in the one case into the spongy metallic state and in the other (the anode) into a complex peroxide. The process might be simply described by supposing that the plates are respectively charged with hydrogen and oxygen. These two elements form water in recombining, which takes place immediately the difference in potential is allowed to force the current through the circuit by the latter being closed externally. In discharging, the active materials—in giving up their hydrogen and oxygen respectively—assume, by virtue of the chemical reactions, their original constitution, and are thus ready for further charging and discharging.



Conductors.—Bodies which readily allow electricity to flow through them. All metals are good conductors.

Non-conductors or Insulators.—Bodies that retard the flow of electricity wholly or very considerably. Glass, shellac, porcelain, mica, guttaperchs, indiarubber and its compounds, vulcanite, etc., are good insulators.

Induction.—The "creation" of a current or electric flow in a circuit, by the circulation of an originating current through an adjacent coil, with which, however, the circuit carrying the induced flow is not in contact. This phenomena is allied to the magnetic production of current.

Difference of Potential.—A difference of potential produces pressure in a circuit in somewhat the same way that a difference of level in water produces pressure, which is apparent when the supply is turned on. So when a circuit is closed, *i.e.*, when a path is made for the current to circulate, the difference of potential produces the pressure and occasions the flow.

Potential.—The power of doing electric work. A natural difference of potential is inherent between most substances capable of being affected chemically.

The Wolseley 96-h.p. Gordon Bennett Racer—Left-hand Side. [See page 145.

Series.—An accumulator is said to be coupled in series when the two cells of which it consists are connected—the positive of the first to the negative of the second—in such a manner that the pressure is equal to the sum of the pressures of the cells so connected, whilst the current given off is the same as that given off by a single cell.

Parallel.—When cells are connected in parallel (all the negatives together and all the positives together) the current given off is equal to the sum of the current of each of the cells, while the pressure remains that of a single cell.

Ampere.—The measure of current-rate or strength. The "rate" at which electricity passes a given point in a circuit is indicated in amperes, a simple illustration being that an ordinary incandescent electric lamp of sixteen candle power takes half an ampere to illuminate it. The "quantity" of electricity is computed in ampere-hours, the capacity of ordinary accumulators ranging from 20 to 60 ampere-hours; which means that they contain a charge equal to a supply of one ampere for 20 or 60 hours respectively, or of, say, five amperes for four and twelve hours respectively. There is a certain discharge rate for an accumulator which must not be exceeded, under the penalty of ruining the plates by buckling.

(To be continued.)

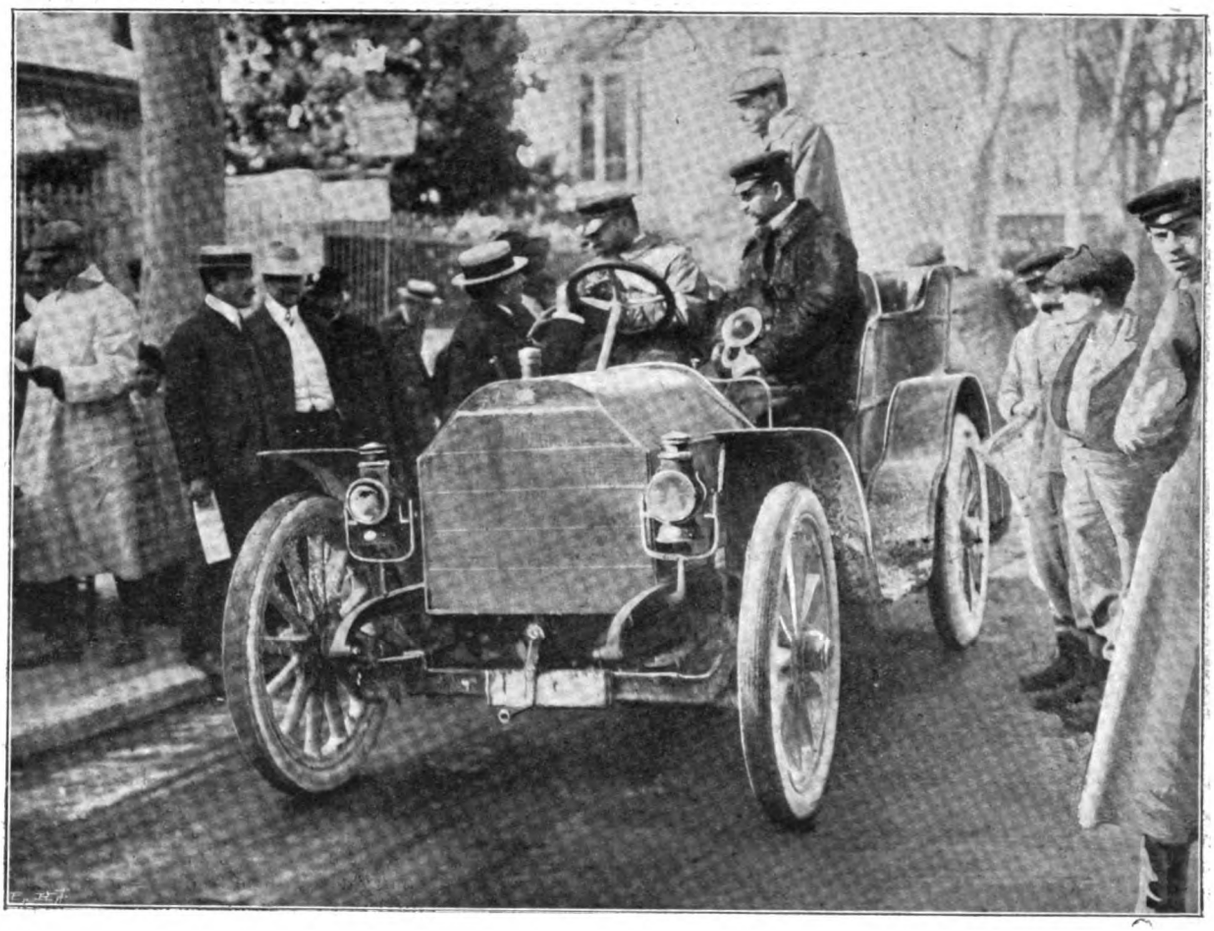
CONTINENTAL NOTES.



Motor-Boat Races at Monaco.

INTEREST in the South of France during the past week centred in the motor-boat races at Monaco. On the 5th inst. seven boats competed in the 8-metre racer class, which had to cover 150 kilometres. "La Rapee III.," with Panhard four-cylinder 35-h.p. motor, won in 4 hours 33 min. In a 60 kilometre race for 6½-metre cruisers, six competed, the winning boat being "La Marguerite," with Mutel four-cylinder engine (time, 3 hours 32 min.). The programme on the 6th inst. included a 200 kilometre race for "racers" from 8 to 12 metres in length, with motors of a maximum capacity of 15 litres, and an 85 kilometre contest for "cruisers" of a length less than 8 metres, and with single-cylinder motors of not more than 3·45 litres capacity. The first event was won by the "Trefle a Quatre," with Georges Richard-Brasier four-cylinder motor, in 5 hours 15 min. 51 sec. The "Napier Minor," which competed in this race, retired owing, it is reported, to pump troubles, and to a slight flare up, which, however, was quickly extinguished. The winner in the second event was "Peugeot III.," with Peugeot four-cylinder motor (time, 3 hours 55 min. 16 sec.). On the 8th inst. the "Vasy," with Delahaye four-cylinder engine, won a 100-kilometre "cruiser" race in 4 hours 25 min. 18 secs., and the "Lutece," with Panhard motor, the "racer" event over a distance of 175 kilometres, in 5 hours 6 min. 9 sec. The most serious accident of the meeting occurred in this race, the "Parisienne II." being destroyed by fire. The boat, which was fitted with three Mors engines of 60-h.p. each, was sailed by Mr. L. C. Currie, nephew of Sir Donald Currie. Before the vessel had gone far a leakage was discovered in the oil tanks, and shortly after the oil took fire. Before they could escape, the engineer and the two mechanics were burnt, and, as it was impossible to subdue the flames, all four men dived overboard. Fortunately they were picked up by another motor-boat and brought into harbour. On Saturday the "Mercedes I." won a 50-kilometre "racer" handicap in 1 hour 32 min. 20 sec., and "Le Nogentais," with Darracq engine, the "cruiser" handicap, this vessel covering the 67·6 kilometres in 2 hours 57 min. 38 sec.

◆ ◆ ◆

Diplomas for Mechanicians.

A PRACTICAL attempt towards solving the problem of thoroughly training men to look after and drive motor-cars is about to be made in France, the Association Générale Automobile having decided to create a special diploma for "mecaniciens-conducteurs." By this means motor-car owners will be able to obtain the names of drivers who could be thoroughly relied on as understanding every phase of their business, while the men who have the enterprise to qualify for the new diploma will be practically certain of finding employment with the utmost readiness. The certificate in question is only to be awarded after the successful completion of severe tests in driving and repairing. A theoretical knowledge of motor-cars will also be an important item in the examination. Every candidate must be able to take the principal parts of the mechanism of a car to pieces and put them together again. Moreover, an accurate and complete knowledge of police regulations, insurance liabilities, customs house formalities, and the necessary steps to be taken for despatching motor-cars by rail or steamship, will be essential. Finally, the physical fitness of the applicant for a diploma will be considered, every candidate being required to undergo an examination by a physician.

The A. C. de Touraine's Touring Competition.

THE Automobile Club de Touraine, of Tours, is organising a touring competition for motor-cars and cycles, to be held from the 12th to the 15th May. The weighing in and examination of

Digitized by Google

vehicles by the jury will take place on the 12th; on the 13th there will be a run of 253 kilometres, followed by one of 251 kilometres on the 14th; on the last day the competing machines will be placed on exhibition and examined by the jury. Category 1 is for chassis costing less than £240; Class 2, ditto from £240 to £480; Class 3, ditto over £480; and Class 4, motor-cycles. The classification in the case of the cars will be by points on the following maximum basis: (a) regularity, 600; (b) fuel consumption, 300; (c) dead load per passenger's seat, 300; (d) average speed, 100; (e) capability of starting on hills, 200; (f) price of chassis, 100; (g) carriage work, 200; (h) ease of starting motor, 100. Entry forms can be obtained from the A. C. de Touraine, 27, Rue Victor Hugo, Tours.

◆ ◆ ◆

International Exhibition at Liege in 1905.

THE international exhibition which will be held at Liege next year (April to November) is certain to be of considerable interest from an automobilist's point of view. There are numerous motor-car works in the district, and, though their names are not so well known as some in France and Germany, yet a large number of cars are turned out. A commercial bureau is to be attached to the exhibition, which, besides giving information concerning it, and also the country, will facilitate the inspection of works in which visitors may be interested. Liege, though one of the largest manufacturing centres of the world, is an ideal centre for pleasure seekers, Spa, Namur, Dinant, Chaudfontaine and the Ardennes all being within easy distance, and the town itself, with its broad river and parks, and wonderful boulevard, well worth a visit. The success of the exhibition, which is in commemoration of the 75th anniversary of the Belgian national independence, may be said to be already assured.

◆ ◆ ◆

Automobile Regulations in Brussels.

THERE has, perhaps, been more trouble in Brussels concerning the regulation of motor-cars than in any other city. For months war was waged between M. de Mot, the burgomaster, and motorists on the speed question, and the courts were kept busy with cases of drivers who had infringed the law. Now litigation has arisen in respect of the lamp which all *chauffeurs* are expected to carry on their cars. A driver having been summoned for not carrying a lamp with opaline glass, he declared that the law required that motor-cars should have a numbered plaque in front and one behind illuminated by a lamp. The magistrate acquitted the motorist on the ground that the regulation of the authorities of Saint Gilles setting forth that every car should carry a lamp with opaline glass was illegal, since it added to the text of the law. Therefore, according to this finding, while the carrying of a lamp is compulsory, it is not necessary that it should be provided with opaline glass.

◆ ◆ ◆

Races at Arras.

IN connection with the exhibition which will be opened at Arras early in May, under the auspices of the Automobile Club du Nord, it has been decided to include in the programme a number of motor-car races and a tour. On May 25th the mile and kilometre trials will be held, while a five kilometre hill-climbing competition is fixed for the 26th. On the next day there will be a 294 kilometre tour to Boulogne and Touquet (Paris-Plage), and on the beach at the latter place, on May 28th, a series of mile trials will be held.

◆ ◆ ◆

A German Reliability Trial.

AN endurance test for motor-cars and cycles is in preparation under the auspices of the Berlin and Leipzig Automobile Clubs. The date of the test has been fixed as May 8th, the course to be Berlin, Potsdam, Wittenberg, Bitterfield, Leipzig, and back, a distance of about 200 miles. The light cars will only run from Berlin to Leipzig. The minimum permitted time is fixed at 9½ hours, and for the single course 4½ hours, the maximum times being 11½ and 7 hours respectively.

◆ ◆ ◆

A New Tyre-Repairing Compound.

MESSRS. MICHELIN have recently introduced a special rubber paste known as "Le Mastic Michelin" for filling up cuts in the outer covers of pneumatic tyres. In application, the hole in the cover is cleaned out thoroughly with naphtha, a coat o rubber solution applied, and the cut is then plugged with the paste.

◆ ◆ ◆

The French Eliminating Trials.

THE Sporting Committee of the A.C.F. has decided that the start of the eliminating contest in the Argonne for the Gordon Bennett Cup team shall be made at Mazagran, at the intersection of the Renthel-Vouzier and Chalons-Aligny roads.

◆ ◆ ◆

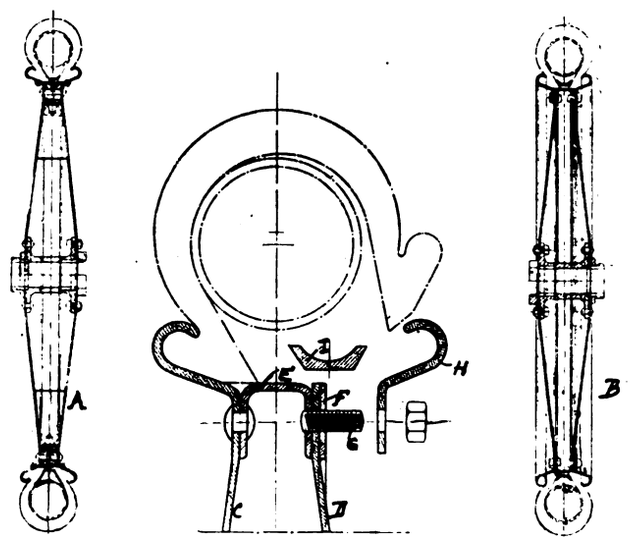
French Motor-Car Exports.

ACCORDING to a return just issued, the motor-cars exported from France last year attained a value of £2,035,680 as compared with £1,208,760 in 1902 and £631,280 in 1901.

◆ ◆ ◆

Automobile Regulations in Sweden.

THE Swedish Minister of the Interior is at present engaged in formulating regulations with regard to motor-car traffic, which will aim at favouring the extension of the automobile industry in Sweden.



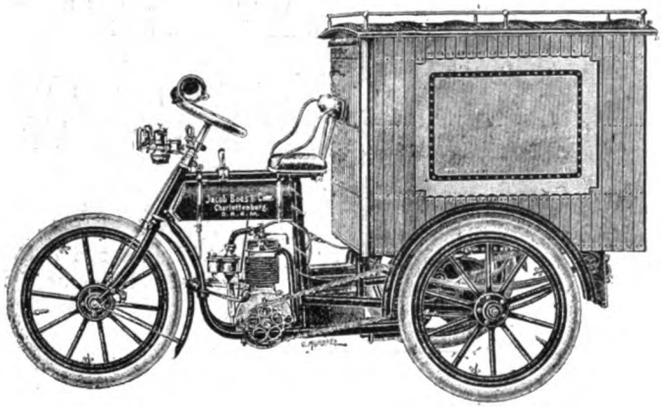
◆ ◆ ◆

Military Motor-Cars in Italy.

THE Italian Ministry of War has decided that in all important garrisons motor-cars are to be provided for the use of the chief officers, and that heavy motor-wagons shall be used in the commissariat department.

THE ARBEL STEEL WHEEL.

IN our report of the Paris Automobile Exhibition we mentioned that steel disc wheels for motor-cars were shown by two concerns. We have already illustrated the Stier arrangement, and now give an illustration of the Arbel steel wheel, which is made by Les Forges de Douai in either of the two forms shown sectionally to the left and right of the illustration. The one shown at A has its rim fixed rigidly to it, while that at B has a detachable type of rim, seen on a larger scale in the centre. This wheel is built up of



two pressed steel discs, C and D, which are riveted with flanged joints to the hub at the centre, and are united at their peripheries by the ∩ rim, E. In the detachable form, the disc, C, is continued up to form one side of the rim, and the disc, D, is reinforced by a ring, F. The detachable side, H, of the rim is held in place by nuts, which fit the studs, G, the thickened edges of the tyre cover being held in place by the curved-over sides of the rim. A saddle-shaped ring, I, is provided between the two thickened edges, and this rests on the rim, E, to form a curved surface for the inner tube to lie in. We may add that the Arbel wheel was used by M. Serpollet on his steam car in some of the races in France last year.

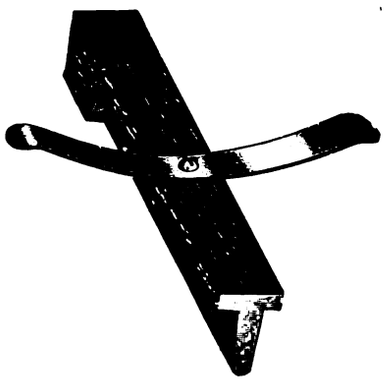
MOTOR-CYCLING NEWS.



FROM the Ariel Cycle Company, Limited, comes a copy of the new catalogue of the Ariel motor-cycles. This is very complete, giving as it does detailed illustrations of the motor, carburettor, silencer, and other parts of these machines. Several pages are devoted to a number of useful hints to users of the Ariel motor-cycles.

A GERMAN firm, Messrs. Jacob Boes and Company, of Charlottenburg, has lately brought out the motor parcel delivery tricycle illustrated herewith. It is intended for tradesmen's

use, and is fitted with a 4-h.p. motor with two speeds—5 and 12 miles per hour—and free engine. The motor-cycle is capable of carrying a load of from 5 to 6 cwt.

THE Triumph Cycle Company, Limited, have lately issued a handbook dealing with the features of their 2½-h.p. and 3-h.p. motor-cycles. One of their most recent productions is a 3-h.p. forecar, with water-cooled engine, the circulation being maintained by pump and radiator. The booklet referred to above will be found useful by riders of the Triumph motor-cycles, as, in addition to descriptions of the various machines, a diagram of the electrical wiring connections and a number of riding hints are given. The various features are also clearly dealt with, among them being the small but important improvement illustrated herewith. It consists of a combined spring and wedging device to hold the accumulators securely in place with-

out undue pressure. The rag-and-firewood packing of the average accumulator case, at best an unreliable way of securing the battery except as a salve to the owner's conscience, is thus dispensed with.

THE Motor Cycling Club are fast completing their arrangements for the all-day run from London to Edinburgh, which will start on May 20th next. This will be an historic event, and one which will attract a great deal of public interest. The legal limit of speed will be strictly observed. This ride is open to members of the club only, and motor-cyclists wishing to join should write without delay to the hon. secretary, Mr. J. H. Reeves, 2, Penywern Road, Earl's Court, London, S.W., as the entries close at an early date.

IMPORTS OF AUTOMOBILES.

BELOW we publish our monthly official list of the imports of motor-cars, motor-cycles, and the parts thereof, into the United Kingdom during the month of January, 1904:—

BELGIUM.

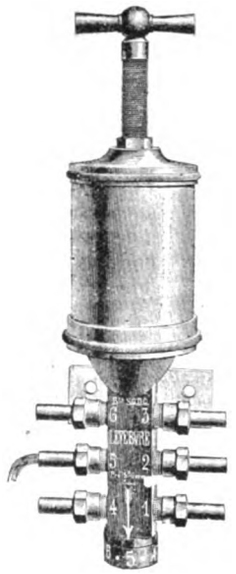
Digitized by Google

SOME USEFUL NOTES.

AFTER an automobile has been run a few thousand miles the mechanism which operates the valves becomes more or less worn, and this affects the working of the valves to a greater or smaller extent. While with ordinarily good care the wear is very little, yet a slight wear on the several parts will in the aggregate amount to considerable. This may be illustrated by the wear on the old-fashioned surveyor's chain, which had 596 wearing surfaces; if each link and ring wore one-hundredth of an inch at each point of contact, the four-rod chain would be lengthened nearly six inches. This is, remarks Mr. F. N. Blake in the "Horseless Age," in effect what happens in the wearing of the valve gear of a petrol car, though, of course, in a different way and to a lesser extent. Power is applied to open the valves, and as action and reaction are equal and opposite in direction, it follows that the parts wear in such places that the lift of the valves is delayed and lessened.

THESE notes are particularly intended to be of interest and assistance to those owners of Oldsmobiles who have not studied the matter, or have not thought enough about it to provide some remedy for the wear whenever it has reached the point where it becomes worthy of attention. Notwithstanding its simplicity, there are in the motor mentioned sixteen wearing surfaces which contribute to affect the lift of the inlet valve, and it does not require much wear on each one to make a perceptible difference with the inlet.



FORTUNATELY it is quite an easy matter to compensate for the wear in a fairly satisfactory manner. A rough and ready way is to enlarge the diameter of the roller under the valve by putting a band of thin sheet metal around it; the thickness needed can be determined by starting the engine and inserting a piece of the material between the roller and valve stem. If this makes the engine run faster, a thicker piece should be tried; if too thick to allow the valve to seat properly, make the piece thinner.

A MUCH better way is to replace the roller with a four sided piece of steel, each side to give a little different lift from the others; this will allow the valve lift to be easily regulated. If desired, one or two sides may be left to be used at some future time, when the wear shall have made another change desirable.

IT may at first be thought that a roller should be used in this place, but a little reflection will show that such is not the case. The lift of the valve is short, the lever lifting it is of fair length, and the arrangement is such that there would be but little friction even if the lever had a solid end. The writer has seen a case where, though the roller was free to revolve easily and had been kept well lubricated, still it had kept the same position so long that the upper side had worn flat an appreciable amount. It was remarkable that with all the thumping and jarring it had received the roller had not turned at least enough to prevent its wearing flat, and it demonstrated that a roller was unnecessary. If a block had been used instead of the roller it would have been as good in every way, and have had the advantage of presenting a larger face, and would thereby have reduced the wear both on itself and on the valve stem. The block should turn freely on its bearing. It cannot shift faces accidentally. If made somewhat after the shape of a Maltese cross it will still be as good and will have the advantage of being lighter. Instead of riveting the pin holding the block, it may be secured by a cotter pin, thus facilitating future adjustments.

THE exhaust valve mechanism is subject to the same wear as that of the inlet, having the same number of wearing surfaces and, in addition, a stiffer spring to work against, and so, having more work to perform, naturally may be expected to wear faster. When, because of this wear, it needs attention, it can be treated in the same way as the inlet. It may be stated that the method described does not restore the original valve action, but it comes so near to doing so that in practice it is not probable that the difference could ordinarily be detected. The difference lies in the fact that, owing to wear on the spiral gear, the action of the valves is delayed a very trifling amount; the other wear reduces the lift of the valves and is of greater importance.

THE accompanying illustration shows an ingenious grease lubricator which has recently been introduced by Messrs. A. Lefebvre Fils, of Prè-Saint-Gervais (Seine) France. Many of the lubricators on the market for lubricating five or six bearings have the fault of lubricating some of these more than others. The Lefebvre device has the advantage of lubricating all the bearings separately, or all together; it is composed of a copper cylinder, through the cover of which passes a screw, used to raise or lower the piston which compresses the grease. The lower part on which the cylinder is fixed is terminated by a distributor with two, four, or six numbered openings, according to the size. Besides the compressing piston, the screw controls a stem, on the lower end of which is fastened a revolving disc, and on which are numbers corresponding to the number of distributors. The stem of the disc is fixed in such a way that by unscrewing the screw which commands the piston (a fifth of a turn at most) it finds itself turned backwards, and turns with it the revolving disc attached to it, bringing the figure that has

been selected in line with the vertical arrow on the lower part of the distributor. Let us suppose a charge of grease has been sent along outlet No. 1, and that it is desired to lubricate No. 5, as is shown in the illustration. It will be necessary to turn the controlling screw to the left until the figure 5 coincides with the arrow. As soon as this happens there is nothing more to do than to turn the controlling screw to the right, as with an ordinary compressor, in order to make the grease pass to the bearing represented by this figure. The disc can only be moved by a backward movement of the screw, and therefore as much grease as may be necessary can be forced along the feeder simply by continuing the pressure. For lubricating all the bearings at the same time, the same rules must be observed, except that in place of selecting a number, one of the points which are to be found between each figure is brought into coincidence with the arrow.

MESSRS. H. H. P. DEASY AND COMPANY, LIMITED, has been registered with a capital of £40,000 to acquire the business carried on in London as Deasy and Company, to adopt an agreement with Capt. H. H. F. Deasy, and to carry on the business of automobile factors, agents, manufacturers, etc. There will be no initial public issue. The first directors (to number not less than two nor more than five) are Major E. de Beaumont, Mr. K. H. Buchanan, and Captain H. H. P. Deasy.

The Motor-Car Exhibition at the Agricultural Hall.

[CONCLUDING NOTICE.]

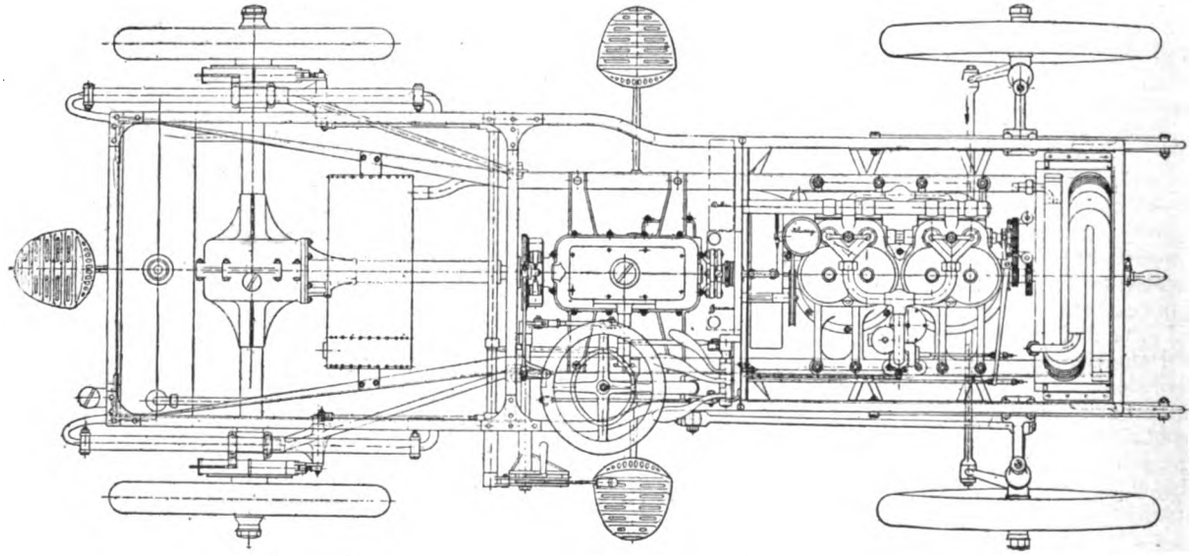
From photo lent by] **The First Exhibition of Motor Cars in England—Tunbridge Wells, 1895.** *[Sir David Salomons, Bart.*

HEREWITH we complete our report of the Motor Car Exhibition at the Agricultural Hall—an exhibition that ranks first among such displays in this country, and that sets a standard which future shows at the same place may be confidently anticipated to maintain.

PETROL CARS.

LA SOCIETE DES AUTOMOBILES FRANCAISES confined their exhibits of automobiles to a "Papillon" 6-h.p. two-seated car. This follows the general lines of chainless cars, its notable feature being the relatively long wheel base. The motive power is supplied by a 6-h.p. De Dion motor. Three speeds forward and a reverse are provided by a gear-box containing the usual sliding gears. A large display of motor-car and cycle components and accessories was to be seen at this stand, including lamps, horns, accumulators, etc. Among the articles of interest to motor-cyclists is a new lever for fixing to the top bar. This is provided with a very simple device, by giving half a turn to which the lever is locked in position, so that the adjustment cannot be disturbed by vibration. La Société Francaise are also the agents for the well-known Buchet petrol motors, and displayed a 2¼-h.p. of this type for motor-bicycles, the cylinder having a bore of 70 mm. by 70 mm. stroke.

MESSRS. J. BARRE AND CO. exhibited, through M. H. Cintrat, a number of four-seated cars notable for their low price and large bonnets. All were fitted with tonneau bodies, and followed the general lines of cardan-shaft vehicles. We first noticed a 12-14-h.p car fitted with a two-cylinder



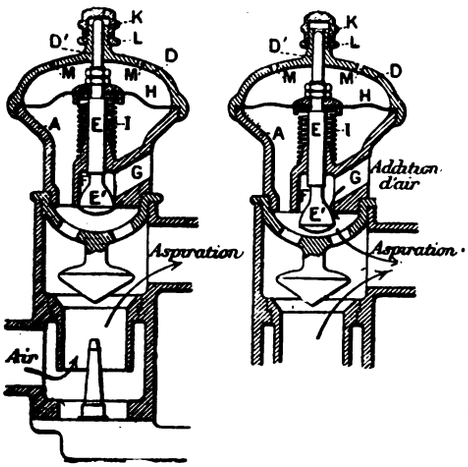


Fig. 97.—Plan of Chassis of 24-h.p. Wilkinson-De Cosmo Car. *(See page 153.)*

Aster motor. The water cooling is by means of a friction-driven pump and honeycomb radiator. Three speeds forward and a reverse are available, while the brakes are of the internal expanding type. A second car had a 9-h.p. De Dion engine, while a third had a similar engine of 6-h.p. At this stand was also to be seen the "Imperator" anti-skid band, which performed so well in the recent anti-skidding trials in France.

Digitized by Google

The WILKINSON SWORD COMPANY, LIMITED, exhibited one of the "Wilkinson-De Cosmo" 24-h.p. cars built by M. J. de Cosmo, until recently the consulting engineer in the motor department of the Fabrique Nationale d'Armes, of Herstal, Belgium. The vehicle is an excellent specimen of modern motor-car construction. The frame is of channel steel, in the fore part of which is arranged a four-cylinder engine developing 24-h.p. The cylinders are cast in two pairs, and are 100 mm. bore by 130 mm.

Figs. 98 and 99.—Sectional Views of Wilkinson-De Cosmo Automatic Carburettor.

stroke, the normal speed being 900 revolutions per minute. The inlet valves are mechanically operated and are provided with a variable lift device. The gas is furnished by a special carburettor, in which the mixture is automatically varied according to the speed by means of a diaphragm. Two sectional views of the latter and its casing are given herewith, H being the diaphragm connected with a valve E. When the engine is running at normal speed, the valve E keeps the additional air inlet G closed, as shown in Fig. 98. On the other hand, when the speed of the engine increases the diaphragm is, under the action of the suction, drawn down, taking with it the valve E, so allowing additional air to be drawn in through G. The automatic governor is adapted to act on the inlet, and can be cut out by means of a pedal. The silencer is of new design, claimed to allow the engine to work quietly at all speeds, without any appreciable back pressure. A framed ribbed radiator is employed in connection with the water circulation, which is maintained by a gear-driven pump. Three speeds and reverse, controlled by one lever, are provided, the engine driving through a clutch, gear box, and cardan shaft on to a rotating shaft inside the rear hollow axle, which carries the wheels, the power being communicated to the latter at the ends. In addition to the usual brakes—of the metal-to-metal type—a ratchet sprag is fitted on the shaft which projects from the rear end of the gear box, to prevent the car running back on hills. The front and rear axles are connected to the frame by long springs, having shackles at both ends, and are fitted with radius rods. By the use of the latter in connection with the front axle the reaction on the steering is claimed to be reduced to a minimum.

Among the exhibitors of popular-priced two-seated cars was the CLYDE CYCLE AND MOTOR CAR COMPANY, LIMITED, whose 7-h.p. vehicle is illustrated in Fig. 100. The motive power is supplied by a 7-h.p. single-

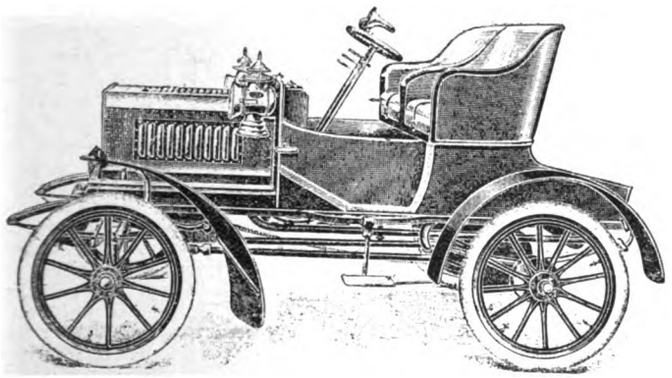

Fig. 100.—The "Clyde" 7-h.p. Car.

cylinder vertical engine, set in the fore part of a tubular frame. A governor acting on the inlet is provided, and this is so arranged that it can be put out of action when desired by means of an accelerator pedal. The water circulation is maintained by a chain-driven pump and radiator. It is in the system of transmitting the power to the rear road wheels that the special feature of the "Clyde" cars lies, all the shafts being parallel to the axles. The engine is connected through a metal-to-metal clutch and a Renold silent chain, with the gear-box at the rear. The latter is adapted to give two speeds forward and a reverse. The makers claim that by their system of transmission a larger proportion of the engine's power is transmitted to the road wheels than by any other method at present in use, and that the car will climb a gradient of 1 in 7 with standard gear and full load. The forward gears are always in mesh. Control is effected by two pedals, one of which actuates the friction clutch, and the other applies two phosphor bronze brake shoes to a large steel drum on the countershaft. Two internal expanding brakes, fitted inside two hollow drums fixed on to the back wheel hubs, and applied by a side lever, are also provided. The motor is started from the right-hand side of the car instead of at the front, as usual. Ball bearings are fitted to the axles and also to the countershaft. There are a number of other interesting details in connection with this car, which pressure on our space prevents us referring to, but we may mention that one vehicle was fitted with an ingeniously-arranged folding seat at the rear, thus enabling it to carry an extra adult passenger or two children. A Clyde 12-h.p. four-seated car was also exhibited. Except that this has a 12-h.p. double-cylinder governor Aster engine and three speeds forward in addition to the reverse, it is identical in arrangement with the 7-h.p. car above described. Finally, we may mention the $2\frac{3}{4}$-h.p. Clyde motor-bicycles with magneto ignition and belt drive, the engine of which is set vertically in a special loop frame.

MESSRS. ALFRED DOUGILL AND CO., LIMITED, had an exhibit of cars which presented some interest by reason of the fact that they are fitted with a friction drive. Many attempts have been made to adopt this simple system of transmission, but hitherto with but little success. Messrs. Dougill claim to have solved the question, and are now building several types of friction-driven cars. Fig. 102 gives a general view of the Frick

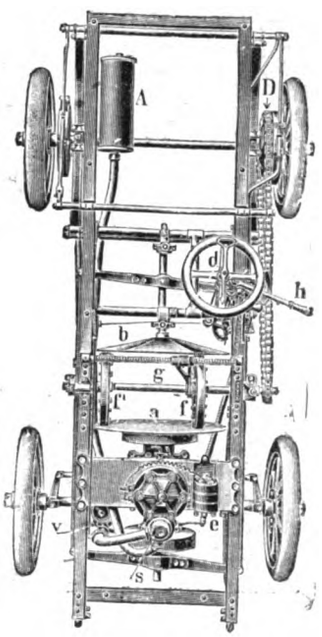

Fig. 101.—Plan of Chassis of Frick 7-h.p. Car.

7-h.p. light car, which we first examined, and Fig. 101 gives a view of the *chassis* showing the friction drive. The 7-h.p. motor is of the single-cylinder type, with balanced internal flywheels, and has a bore of $4\frac{1}{4}$ in. by $4\frac{3}{4}$ in. stroke. It is placed in the front part of a wood and steel frame under a bonnet in the usual manner. The ignition is either by accumulators or magneto, and the water circulation is maintained by a belt-driven pump and fan-cooled honeycomb radiator. The engine drives through enclosed reduction gear and a short shaft terminating in a leather-covered disc *a* (Fig. 101), forming part of the friction drive, which gives any desired speed, ranging from zero to maximum in either direction, and operated by a lever conveniently placed for the driver, and by a pedal. Reference to Fig. 101 will show two friction wheels *f* and f^1, of which wheel *f* is the actual working disc, and f^1 a dummy disc, serving to increase the surface of friction. The disc *f* can be moved on its shaft *g* in the direction of its axis, in order to attain different degrees of speed, whilst f^1 transmits the power from the disc *a* through counter disc *b* to the wheel *f*. By moving the hand lever *h*, the discs *a* and *b*, which slide in the direction of their axis, are brought into contact with *f* and f^1, by which the latter are set in motion. The drive from the countershaft *g* to the differential gear *d* on the continuous rear axle is by means of a single side chain. When the friction wheel *f* is near the centre of the flywheel the car is on its lowest speed. When this wheel is moved over the centre line of the disc, the direction of rotation of the shaft *g* is reversed. Among the claims made for the friction drive are: (1) Speeds can be gradually increased at will. (2) It has a direct transmission without gear wheels. (3) It is simply constructed, enabling worn-out parts to be easily replaced. (4) Great economy of motor power up hill and on the level with a minimum consumption of petrol. The car

Digitized by Google

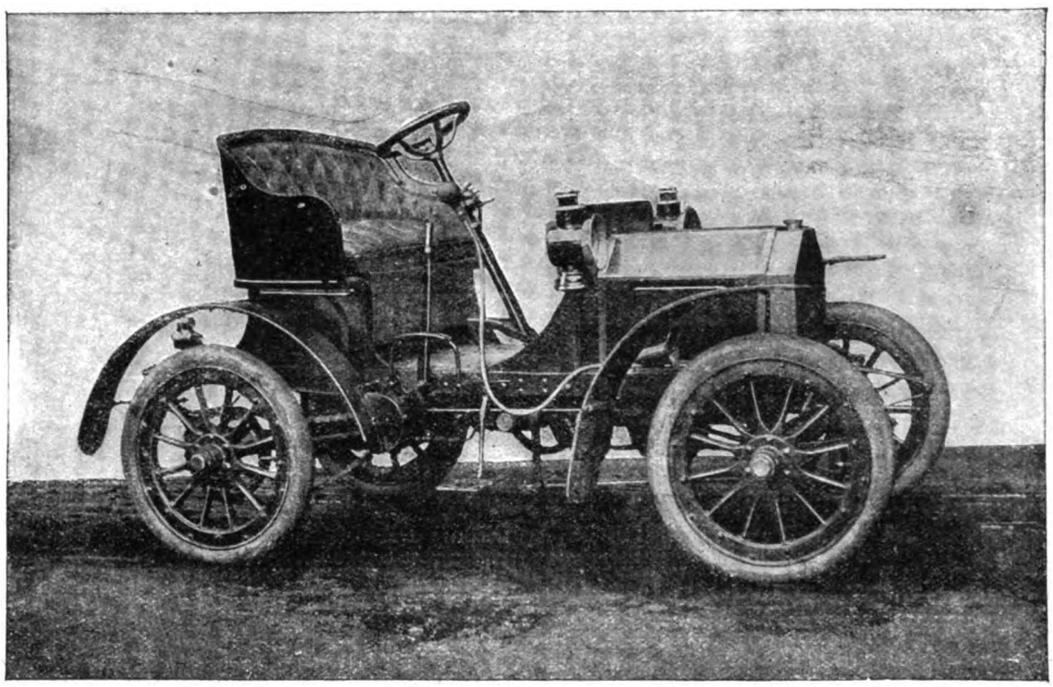
is provided with powerful brakes, one operated by the foot, acting on the countershaft, while another pair, controlled by a hand lever, act on two drums on the hind wheels. The body has seating accommodation for two persons. A spider seat for a third passenger can be attached at a small extra cost, while a detachable tonneau can, if necessary, take the place of the ordinary body. The wheel base is 6 ft. and the track 3 ft. 8 in. The wheels are of equal diameter (34 in.), shod with solid or pneumatic tyres. Messrs. Dougill also exhibited a little 5-h.p. two-seated car, as well as a 12-h.p. two-cylinder lorry to carry two tons, both having the friction drive referred to above. In addition, a 9-h.p. "Loidis" tonneau car was shown. This follows the general lines of bevel-gear driven cars, having a 9-h.p. Aster governed engine mounted in the fore part of a tubular frame, three speeds forward and a reverse being available.

The chief feature of interest at the stand of the BURLINGTON CARRIAGE COMPANY, LIMITED, was the *chassis* of a new car made from the designs of Herr Bugatti, at the German works of the De Dietrich Company, and which they are introducing into this country under the name of the "Burlington." The car, of which an illustration was given in a recent issue of the *Journal*, and which is made in two sizes, 24-28-h.p. and 30-36-h.p., differs materially from the French De Dietrich vehicles. In the first place the engine and gear box are mounted on a frame entirely separate from and attached to the main frame by four bolts. The motor is a four-cylinder one, and possesses mechanical inlet and exhaust valves, actuated by two symmetrical shafts arranged on both sides of the motor. The position of the valves on the top of the cylinders permits them to be easily inspected and detached. On the upper surface are situated also the sparking plugs and the four compression cocks. A novel feature of the engine is that the cylinders are cast in pairs, each pair being surrounded by a removable sheet copper covering. The removable water-jacket facilitates the formation of the cylinder body and permits hollow spaces to be provided everywhere, so that all the walls of the explosion chambers, valve seats, etc., can be plentifully surrounded with cooling water. A special form of carburettor is employed to furnish an automatically-regulated mixture in connection with the advancing of the ignition, so giving the motor great elasticity, and allowing of any desired speed from six miles per hour up to the maximum speed without changing gear. Four speeds and reverse are actuated by one lever, the transmission from the differential shaft being by means of side chains. On the stand of the Burlington Company were also to be seen a *chassis* of the French De Dietrich (Turcat-Mery) 16-h.p. four-cylinder car, the 1904 features of which have already been dealt with in the *Journal*. Special reference may be drawn to the carriage work of these vehicles, a 16-h.p. car with special Lonsdale body and a 12-h.p. with Burlington body being particularly noticeable.

The British-built Duryea cars of the DURYEA MOTOR COMPANY have so recently been dealt with in the *Journal* that no lengthy reference is necessary on the present occasion. A *chassis* and complete car with folding front phaeton body represented the 12-h.p. type, while of the 15-h.p. a *chassis* and side-entrance double phaeton were displayed. The engines and principal machine parts are made by the well-known firm of Messrs. Willans and Robinson, Ltd., of Rugby. The three-cylinder engine with all parts interchangeable, mechanically-operated valves, governed magneto ignition automatically advancing and retarding the spark according to the speed of the engine, the speed variation obtained by throttle worked from the steering handle, the unique system of springing and braced fore carriage, together with the novel system of radiation, are all features of interest to be found in these cars. The Duryea Company also exhibited the Cinderella jack, a handy little instrument which will support any car weighing up to a ton. The jack weighs under 3 lb., and folds up into a space small enough to allow it, if needed, to be put in the pocket.

The GORDON MOTOR COMPANY was among the exhibitors of popular-priced two-seated cars. The motive power is supplied by a 6-h.p. vertical engine, having water circulation by pump and honeycomb radiator. Three speeds and a reverse are provided, the engine being connected by a chain with the gear-box, a second chain conveying the power to the rear live axle. The engine has a large diameter flywheel, and the clutch is so mounted that it can quickly be taken out if required.

The KYMA CAR COMPANY, LIMITED, exhibited their novel two-seated cars. The body is constructed of wicker, and is hung on special springs, which make it very easy riding. It is made in two varieties, one with a 4-h.p. water-cooled motor, the other with a 2¾-h.p. air-cooled engine. In both patterns the transmission is by chains from the motor to a secondary shaft, and from thence to the driving wheels by flat belts. Two speeds, varying from six to twenty-five miles an hour, are provided, with free engine, and friction clutch operated by a pedal. Steering is by a wheel on an inclined shaft, to which all control levers are brought, within easy reach of the driver's hand. The engine is placed in a vertical position in front of the car. The two speeds are obtained by the aid of a feather, by means of which either one of the pair of enclosed chain drives from the engine to the countershaft can be made to transmit the power. No differential is used, the rear wheels being allowed to overrun each other in turning corners, by means of a free-wheel clutch in one of the small belt pulleys.



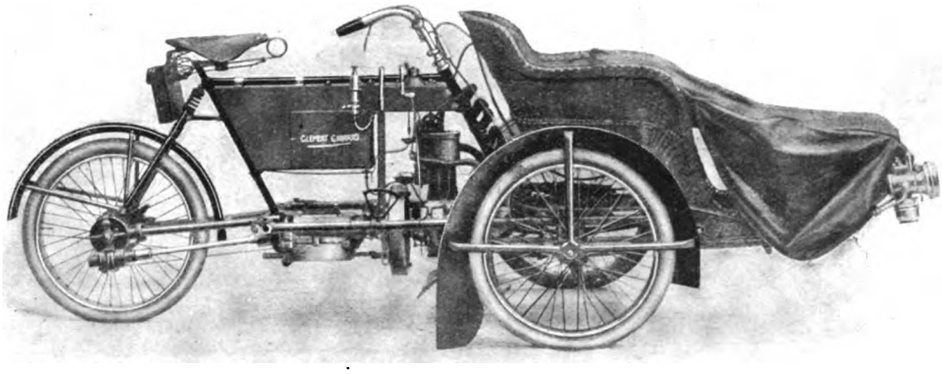


Fig. 102.—The Frick 7-h.p. Light Car.

GOODALL'S AUTOMOBILE AGENCY had on view one of the 8-h.p. Achilles cars made by Messrs. B. Thompson and Co., Limited. The frame is of tubular construction. The vertical engine, of Messrs. Thompson's own construction, has a cylinder 100 mm. bore by 110 mm. diameter, and runs at a speed of from 1,500 to 1,600 revolutions per minute, its speed being controlled by means of the ignition and a throttle valve from the steering column. The water circulation is maintained by a gear-driven pump. Three speeds forward and a reverse are controlled by one lever; on the top speed the drive is direct, none of the gear wheels on the side shaft rotating. From the gear box the power is transmitted by a cardan shaft, having two special universal joints and bevel gearing, on to a live axle. The differential gear is of the spur wheel type. The brakes are of the metal-to-metal variety. The car exhibited had a two-seated body and an extra long wheel base, and attracted considerable attention by reason of its moderate price.

On a prettily-decorated stand in a corner of the Large Hall the CONSOLIDATED AUTOMOBILE COMPANY, over the destinies of which Mr. Allan C. Instone presides, were shown specimens of the 18-28-h.p. 1904 and 18-24-h.p. 1903 Mercedes cars, both having tonneau bodies, and finished in the usual Cannstatt red. A coupie of 10-h.p. Panhard cars with tonneau bodies were also on view, these being fitted with the Krebs carburettor.

Digitized by Google

One of the most interesting departures in the Show was the Suspended Tri-car shown by the Garrard Manufacturing Company, Limited, and of which an illustration is given in Fig. 103. In general appearance it resembles a motor-cycle with the fore-carriage, but closer inspection proved it to be quite a distinct type. The frame is built on cycle lines—that is, of steel tubing, with lugs brazed on where the engine and change-speed gear box are attached. The rear part of the frame is hinged, and the road shock is absorbed by a spring at the top of the triangle. The spring is used in conjunction with a link motion, which ensures all movement or displacement taking place in the correct direction. The fore part of the frame is carried on springs of great length (31½ in.), very wide and thin, to its previous position. This is done to prevent the engine racing, which would otherwise take place when the clutch is withdrawn. A pair of band-brakes, actuated by hand through a Bowden wire, are fitted to the front wheels, the pressure on each side being equalised. The clutch and back-brake levers are under the feet, as in a regular car. Provision is made for very readily detaching the back tyre completely, in case of need, without removing the wheel. Altogether the vehicle is an interesting production, and we are not surprised to learn that it has already met with a favourable reception at the hands of the motoring public. At this stand the Civil Service Motor and Cycle Agency, Limited, the London agents for the Garrard Company,

. 103.—The Garrard Suspended Tri-Car.

he front seat being also suspended on C springs. The engine is of 4½-h.p., water-cooled, with radiator and thermo-siphon circulation and outside flywheel. The cylinder is 85 mm. diameter by 100 mm. stroke. The usual high-tension ignition is provided, and the mixture is furnished by a float-feed spray carburettor. In the flywheel is fitted a friction clutch, worked by a pedal on the right foot-board. Ths clutch is leather faced and conical, but, instead of the male cone being withdrawn to disengage, it goes inwards. The change-speed gear box is firmly attached to cross tubes of the frame, and provides three speeds by means of sliding gear wheels of the Panhard type, which engage with one or other of three corresponding pinions on the main shaft. The countershaft is set slightly out of centre to bring it in line with the gear or the rear hub, which is of the skew type, and contained in an oil-tight case. The connection between the two is by means of a shaft with universal joints to allow for the rise and fall of the frame. The tank has three compartments—the forward for water; next to that, with air space between, is the oil; and the largest is for petrol. The coil and batteries are carried in a box at the side of the seat. The three wheels are equal 26 in. by 2½ in., with, of course, pneumatic tyres, and the weight of the complete vehicle is 3½ cwts. The Tri-Car is fitted with three brakes; the back one is a powerful band brake, controlled by a foot lever, which is also connected with the clutch and throttle. Normally, the throttle and ignition are actuated by hand, but when the brake is applied the throttle is closed to "dead slow." When the brake is released the throttle returns

displayed a new detachable non-skid and puncture preventer, known as the "Envelope."

In addition to one of their 9-h.p. single-cylinder cars, the Rex Motor Manufacturing Company, Limited, exhibited a couple of the 12-h.p. "Rex-Simplex" vehicles, one having a brougham body and the other a tonneau. The engine, which is mounted on the fore part of a steel frame, has two vertical cylinders, 4 in. diameter by 4½ in. stroke. A feature of the engine is that no outside fly-wheel is employed, each connecting rod being attached to a couple of discs acting as flywheels inside the crank case. The exhaust as well as the inlet valves are located in the top of the cylinder head, the exhaust valves being operated by a side rod and suitable levers very much in the way adopted in the Buchet engines. The gear box is adapted to give three forward speeds and a reverse, with a direct

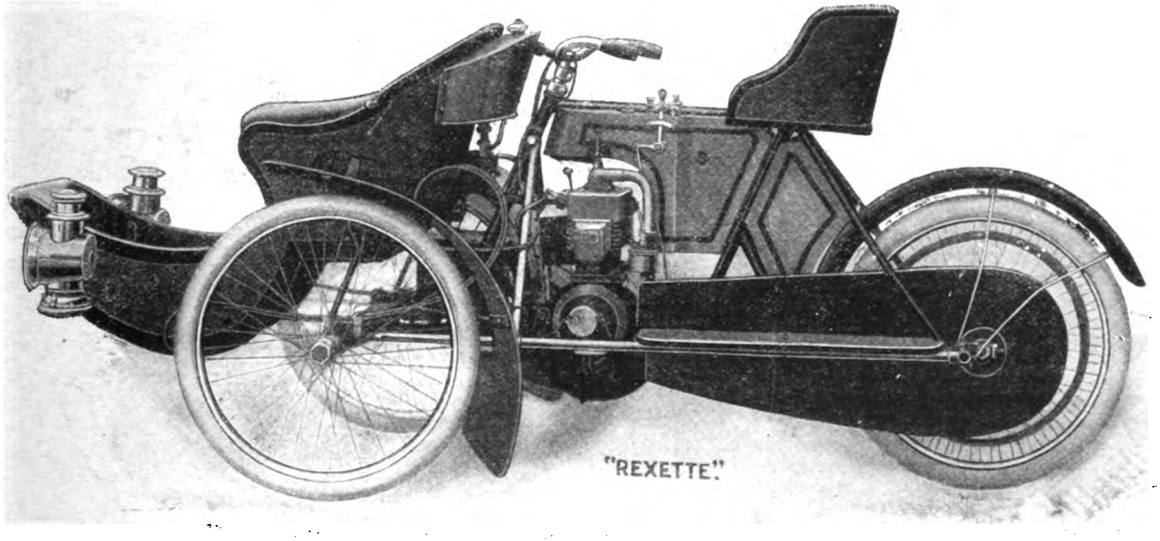

Fig. 104.—The 4-h.p. "Rexette."

drive on the third. Very wide pinions are employed in the gear box; the cardan shaft and bevel gear system of transmission on to a live axle is adopted, universal joints being introduced not only in the cardan shaft, but between the gear box and the clutch. The latter is of the cone type, 15 in. in diameter, and can be readily dismounted without disturbing the change speed gear. On the same stand were shown a number of the popular Rex motor-bicycles and tri-ottes. A description of the latter, with an illustration, was given in the *Journal* for the 19th ult. Fig. 104 illustrates the 4-h.p. "Rexette," a vehicle designed for two passengers, and appealing to moderately-incomed motorists by reason of its economy and simplicity. It possesses two coach-built bucket seats, one being attached in the form

Digitized by Google

of a fore-car and the other at the back in the place of the usual saddle. A water-cooled engine of 4-h.p. drives the little car, and this is rigidly fixed to a registered design of cradle, which permits of its being easily removed when necessary. The vehicle is started by a fixed handle after the practice of ordinary cars. The engine power is transmitted by a chain, enclosed in the gear case, through a clutch to the rear wheel. An exhaust lifter with trigger action and controlled from the handle-bar is provided. The road wheels are 28 in. diameter shod with 2¼ in. tyres. The extreme

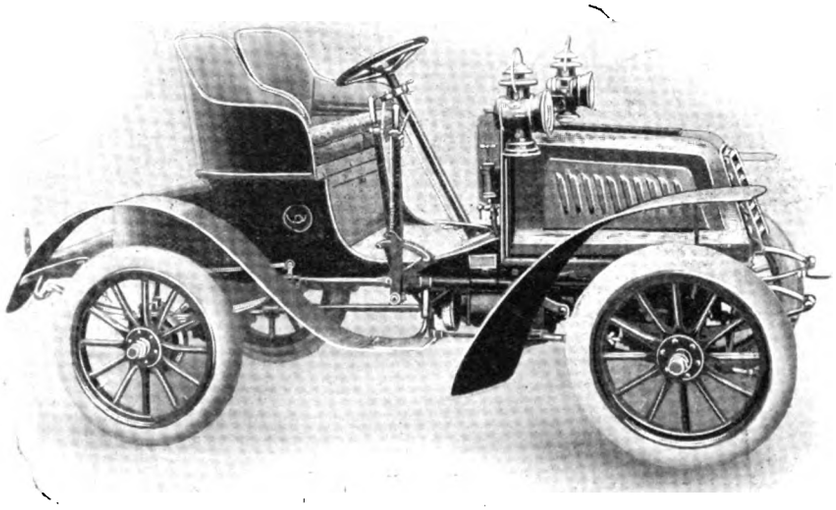

Fig. 105.—The Speedwell Standard 6-h.p. Light Car.

length of the vehicle is 9 ft., and the width 3 ft. 10 in. The framework is of strong tubular construction, and both hand and foot brakes are provided.

The SPEEDWELL MOTOR AND ENGINEERING COMPANY, LIMITED, devoted the major part of their stand to an interesting display of their Speedwell light cars, which, in view of their relatively low price, are meeting with considerable favour. The cheapest is the "Speedwell," which has carrying capacity for two persons and luggage, and is fitted with two speeds forward and reverse. The frame is of tubular construction, being 8 ft. over all, with 5 ft. wheelbase. The engine is a 6-h.p. De Dion. Pan-hard-shape bonnet and radiators, with pump circulation, are provided, as well as artillery wheels fitted with 700 by 65 mm. heavy Clincher pneumatic tyres. The "Speedwell De Luxe" car can be obtained with either a two or four-seated body; the motive power is supplied by a 6-h.p. De Dion engine fitted with a new throttle control on clutch pedal, by means of which, when the clutch is disengaged, the engine is automatically prevented from racing; the throttle is also independently operated by a lever on the steering column. Ease of starting the motor has also been increased by the adoption of a high-speed trembling coil, together with a positive make contact with roller bearing; half compression is also provided. The water-cooling is of the latest design, having a self-contained radiator and circulation by centrifugal pump driven off the flywheel. The gear box gives three speeds forward and reverse, with direct drive on top speed. Lubrication is efficiently provided for, an oil reservoir on the dashboard with a three-way pump attached enabling oil to be sent, at will, into either the back axle, gear box, or motor. A light clutch of the usual cone type is fitted, operated by the left-hand pedal, the right-hand pedal actuating a band brake on the driving shaft, as well as simultaneously re-easing the clutch. There are also two double-acting brakes on the rear wheels operated by side hand lever. The *chassis* is of the long type, with 6 ft. wheelbase, and the frame is constructed of wood and steel flitch plates. The petrol tank has a capacity of about four gallons. There is ample room beneath the front seat for tools, etc., and in the two-seated cars excellent accommodation for luggage is provided on the platform at the rear. The wheels are equal size, artillery pattern, and shod with 700 by 85 mm. heavy tyres. A new model is the special Speedwell, with a 9-h.p. single-cylinder De Dion engine. This type resembles in most of its details the 6-h.p. cars, but, besides a larger engine, it has much stronger gear and driving mechanism and stronger tyres. For those desiring a double-cylinder car at a moderate price the 10-h.p. Speedwell De Luxe has been introduced. The motor has mechanically-operated valves and honeycomb radiator. The wheelbase of the car is 7 ft., enabling a roomy four-seated body to be fitted.

One of the most interesting exhibits in the Gallery was that of the PUTNEY MOTOR COMPANY, which is devoting considerable attention to the manufacture of petrol motors, both for cars and launches. We first examined a four-cylinder motor intended for a special car this company is building for the Earl of Norbury. The four cylinders are cast in two pairs without water joints, the dimensions being 4¾ in. bore by 5 in. stroke. The inlet and exhaust valves are interchangeable and mechanically actuated off a single cam shaft. The latter can be taken out by removing the end plate, in which one of its bearings is seated, this removal rendering the whole of the crank case open for examination. Another excellent feature of the design is to be seen in the valve-rod guides, which can easily be removed, being yoked in pairs to the crank case. Still another point is the securing of the gudgeon pin in the piston, this being held in two lugs, bolted through the piston-head and held by two turret nuts. This not only allows the use of a short piston and connecting rods of maximum length, but prevents any scoring of the cylinder walls. Perhaps the most noticeable feature of the motor is that the crank-shaft is set slightly in advance of the cylinder axis, thus reducing, it is claimed, shock, and lessening vibration by giving a practically direct thrust on the driving stroke, and therefore more power, besides a mechanical advantage at the end of the compression stroke. The diameter of the crank shaft itself is graduated from 1½ in. at the forward to 2 in. at the rear clutch end. An automatic governor is provided, this acting on a piston throttle valve on the admission pipe near the carburettor. The engine runs normally at 950 revolutions, at which it develops 32-b.h.p.; its speed can, however, be varied from as low, it is claimed, as 65 revolutions per minute up to 1,600 revolutions. The Putney Company are making engines of this type with one, two, and four cylinders, of respectively 8, 16 and 32-b.h.p. The usual high-tension ignition is provided for; the commutator is, however, of special design, it being self-adjusting and self-cleaning. It has a roller wipe contact with a quick break, and is so arranged that a short circuit is rendered impossible, the insulating fibre being cut away between the four contacts. A bevel glass window is provided, so that the working parts can be inspected without opening the case. The Craig-Dörwald carburettor also merits attention. It consists of a gravity-fed float chamber supplying petrol to a visible jet. A large vaporising chamber surrounded by a jacket, through which the exhaust gases can be circulated, affords a perfect mixture at all speeds. Fig. 106 depicts the commercial traveller's brougham exhibited by this company, and which attracted considerable attention. The car was

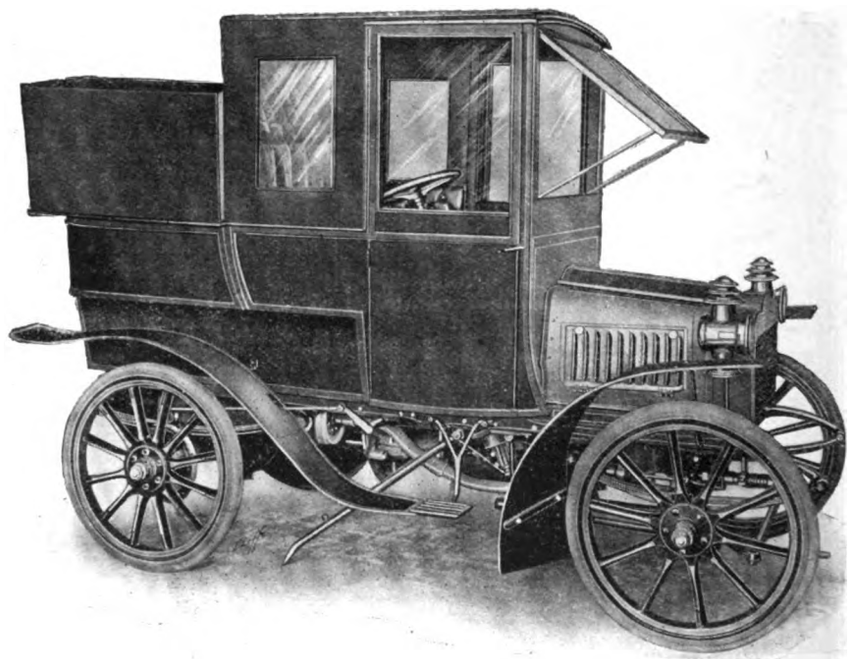

Fig. 106.—The Putney Motor Co.'s Commercial Traveller's Brougham.

specially designed to stand the everyday wear and tear to which such a vehicle is put. In the service of a Manchester firm the car shown has covered over 5,000 miles in the districts around London and in the Southern counties, carrying a load of ½ ton of samples. The interior of the brougham is comfortably upholstered and furnished with writing desk and electric light. The car is controlled entirely from within and accommodation is provided for two passengers, who are perfectly protected from the

Digitized by Google

weather. The upper part of the rear can be removed at will, thus converting it into a tonneau with accommodation for four additional persons. The engine is a 16-h.p. Craig-Dörwald two-cylinder, developing 24-h.p. on the brake. The water circulation is on the thermo-syphon system, the large amount of water contained round the combustion head preventing, it is claimed, any liability to overheating, and doing away with the pump. The power is transmitted through a large leather-faced clutch, gear box and cardan shaft to the rear live axle, three speeds forward and a reverse, with direct drive on top speed, being available.

Messrs. Selbach, Limited, made a special feature of the Regal car, the points of which should appeal to the "man of moderate means" as well as to the more wealthy motorist. This has a 6-h.p. De Dion engine, with a carburettor of the same make, and is also made of 10–12 and 24-h.p. In the smaller size a centrifugal pump, driven by friction off the flywheel, circulates the water through the radiator in front of the bonnet. The water tank is placed above the motor, so that should the pump fail to work no damage would result, the water being circulated by gravity (thermo-syphon). The ignition is on the high tension system. A conical friction clutch, which can be connected to and disconnected from the flywheel by the left pedal on the footboard transmits the power to the change-speed gear. This clutch is of the internal type, all enclosed in the flywheel, so that oil and dirt cannot get to it. The change-speed gear provides two speeds forward and one reverse, operated by the same lever; the drive is direct on the top speed, so that the power is transmitted direct from the motor to differential on live axle. A universally jointed shaft connects the speed gear to the differential, which is of the spur-wheel type. The forward speeds are 7 and 20 miles an hour, and a reverse speed is also fitted. The right pedal actuates, by means of rod connections, a large band brake, the drum of which is on the shaft at the back of the gear box. The side brakes are actuated by a lever; the hubs of the driving wheels contain two segments, which, when expanded, can block the wheels if necessary. The two sets of brakes are metal to metal, and double acting. The car is fitted with a two-seated body.

The Paddington Motor Car Company, Limited, which has secured the British agency for the Tony Huber cars, displayed examples of the 8-h.p., 16-h.p. and 25-h.p. vehicles of this type, the main new features of which were dealt with in our report of the Paris Salon in December last. The 8-h.p. car has a wood and steel frame, in the fore part of which is set a vertical double-cylinder engine, 98 mm. bore by 105 mm. stroke. All the valves are mechanically actuated off one cam shaft, and the water circulation is maintained by pump and fan-cooled honeycomb radiator. Three speeds forward and a reverse with direct drive on top speed are provided. From the gear box the power can be transmitted either by cardan shaft and bevel gear, or through a differential shaft and side chains, as desired, examples of both systems being shown. The 16-h.p. Tony Huber car is an enlarged edition of the 8-h.p., having a four-cylinder engine cast in two pairs, and of the same bore and stroke as the two-cylinder engine. Both Eisemann magneto and the usual high-tension ignition are provided, while the gear box is adapted to give four speeds forward and a reverse. Like the 8-h.p. car, the transmission can either be by side chains or cardan shaft. Considerable interest was shown in the *chassis* of a 25-h.p. Tony Huber car, which is on modern lines throughout. The frame is of pressed steel, and the engine has four separate steel cylinders to which corrugated copper water-jackets are fitted. The valves are all mechanically actuated off one cam shaft.

A light two-seated car was shown by the Anglo-French Motor Syndicate. The motor is a 6-h.p. De Dion, the transmission being by means of a change-speed gear of the sliding type, affording three speeds and reverse on a single side lever. A De Dion-Bouton spray carburettor is fitted, the ignition being by trembler contact breaker and dry battery. The radiator is located in front underneath the frame, the water circulation being by centrifugal pump friction-driven off flywheel. Inclined wheel steering has been adopted, and the car is well calculated to meet the demand for a light car at a moderate price.

In the Gallery the Automobile Engineering Company attracted attention to their "Planet" cars, the light vehicle with a 6-h.p. De Dion engine being an automobile meeting with much favour. This is a two-seated car fitted with two speeds and reverse, the transmission being by cardan shaft to live axle, with a direct drive on top speed. A larger car, with a 12-h.p. two-cylinder Planet engine, and a 24-h.p. Prunel car were also on the stand. A minor exhibit of interest and importance was the "Peerless" sparking plug introduced by this company.

GENERAL EXHIBITS.

A useful exhibit was made by the Auto Machinery Company, Limited, who made a feature of the "Auto" patent roller bearings for main shafting and other shafts requiring a split bearing. As a rule, this type of roller bearing is made with the halves of the outer bush having a straight line abutment. Friction ultimately causes this to wear into a groove, into which the rollers have a tendency to work. In the "Auto" bearing, however, this straight line abutment is discarded, the two halves of the bearing surface being each formed with a deep serration, which interlocks, and gives practically a perfect cylinder when in position. The bush is a steel casting recessed at each end to receive the cage ends; provision is also made for lubrication, and the globular formation in the centre of the bush makes the bearing self-aligning. For light work the company have brought out a roller bearing having a mild steel cage with naturally hard cast-steel rollers. For light loads and low or intermittent speeds this type is recommended. At the stand of the Auto Machinery Company we also noticed the "M" type of ball bearings for motor-cars, etc., in which are some improvements that have been patented, and which contribute to the life and efficiency of the bearing in a marked degree. An air-cooled cycle-motor, and a selection of balls and other productions of the Company, completed a really notable display.

A good type of motor-cycle lamp was on the stand of Mr. G. Goldschmidt, sliding panels being the distinctive feature, so that the numbers are always illuminated. A good display of motor-lamps, horns of every kind, and motor goggles in great variety, was the feature of a meritorious exhibit.

The South British Trading Company made a feature of the Fisk tyre, illustrated and described in the *Journal* of December 12th last. They also showed laminated wood rims, the Lobee circulating pump, and some useful tools for manufacturers. On this stand we also noticed the "Vindec Special" motor-cycle. This has a 2¾-h.p. F.N. engine, with the points exposed to heat so placed as to receive the direct advantage of every air current. To the carburettor is fitted a patented air regulator to allow the admission of cool air to mix with the carburetted mixture from the spray nozzle. To ensure absolutely clean petrol, and to reduce the possibility of the nozzle becoming clogged to a minimum, the spirit, in addition to passing through a fine gauze before leaving the tank, is forced to pass through another fine gauze before entering the spray nozzle from the float chamber. Two band brakes, a V-shaped belt for transmission, and a good type of contact breaker are other excellent features of a motor-bicycle of which much should be heard during the coming season. A useful pamphlet of nearly sixty pages on the management of the machine has been issued by the South British Trading Company, Limited.

Messrs. S. Smith and Son's compensated speed indicator has become rapidly familiar in motoring circles, the high grade character of the watches and clocks made by the firm having given confidence to motorists in adopting the latest introduction of the firm. Although a description of the special instrument at their stand at the Exhibition has already appeared in the *Journal*, a few lines may be given to draw attention to its merits. The mechanism of the instrument is so constructed that the indicating hand is driven from the centre of the dial, which places a complete circle at disposal for the spacing of the various miles, giving a clear and distinct reading for all speeds from 5 to 60 miles per hour. The spacings for the higher speeds are nearly as uniform as in the lower half, and it is in this important improvement that a great distinction for this indicator is claimed. With the introduction of an auxiliary power which comes into action from 25 miles upward, the makers are enabled to give an absolutely correct reading and not an approximate one. An equally important feature is that the instrument can be thrown in or out of gear by means of a patent clutch. Naturally, the method of attachment is an important detail, and this has been scientifically considered by Messrs. S. Smith and Son, who have adopted a flexible shafting for the connection between the instrument and the wheel of the car. Those who have a preference for positive gearing can have their wishes carried out in the attachment. Practical motorists have recognised

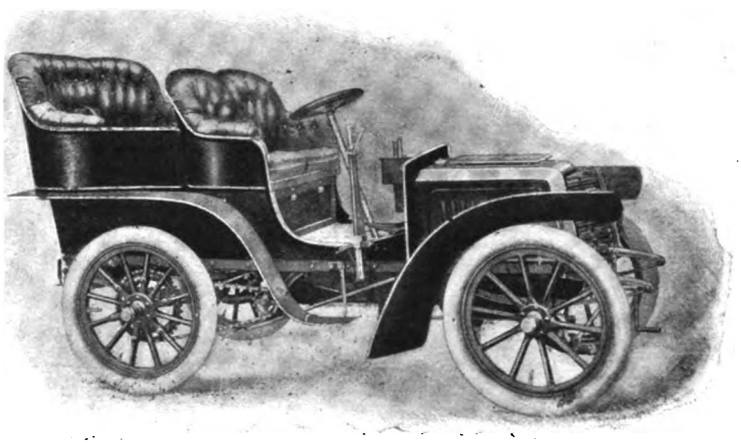

Fig. 107.—The 12-h.p. Chenard-Walcker Voiture Legere, with High-back Tonneau.

the merits of the invention, and have given conclusive tests as to its accuracy under all conditions.

Two stands—one in the Minor Hall and another in the Gallery—served to demonstrate the comprehensive character of the Bowden specialities. A Clement car was exhibited with the ignition, throttle, air and lamp controls actuated for the steering wheel by means of the Bowden wire mechanism brought out by the E. M. Bowden's Patents, Limited. The brakes and sprags are also operated by the same system. How thoroughly this can be adapted was shown by the screen fitted to the lamps, which can thus be utilised to minimise the bright glare as suggested by the Local Government Board. A quadricycle actuated equally comprehen-

Digitized by Google

sively by the Bowden wire mechanism was also shown. In the Gallery the firm showed the Bowden motor-bicycles fitted with 2-h.p. and 3-h.p. F. N. engines placed in a vertical position. All the parts are of standard design and good workmanship, the special features being the handle-bar control, chain drive, and friction clutch in the hub giving a free engine. Several of their specialities were shown; and attention was drawn to the many ways of applying the Bowden wire mechanism.

The North British Rubber Company, Limited, made a creditable display of the Clincher and Clincher-motor tyres, the Clincher motor-cycle tyres, Clincher solid tyres, etc. The company is putting on the market a new tyre known as the "Ducasble," which is designed to meet the requirements of those who do not care for the trouble and expense of pneumatic tyres. It is claimed to absorb the vibration to a great extent. The accompanying illustration gives an idea of the form of the tyre, which is compressed by a special process while being manufactured. In this way the gaping open of cuts and abrasions is prevented, the life of the tyre being thus considerably lengthened. Among the advantages which the North British Rubber Company (Ltd.) claimed for the Ducasble tyre are its non-liability to puncture, and the great resiliency, owing to the hollow construction. The flat tread is intended to obviate any tendency to side slip. The tyre cannot be twisted or jerked out of the rim, owing to the presence of steel bands and security bolts. In addition to their full assortment of tyres the company also made a great show of motor clothing and requisites.

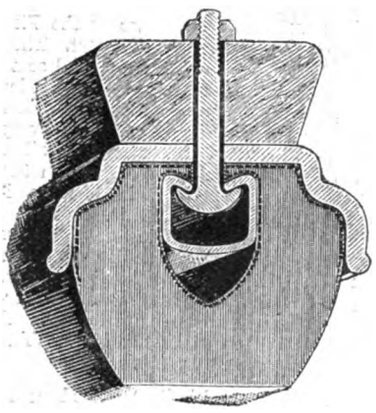

Fig 108.—The Ducasble Tyre.

"Garlio," a non-inflammable cloth for polishing metal, was shown by Messrs. M. and E. Marx, who have now acquired the agency for this useful help to motorists in keeping bright the metal parts of their cars. Messrs. W. B. Fordham and Sons, Limited, made a good show of the "Selvyt" polishing cloths in both single and duplex texture, and also of "Selyvt" gloves, aprons, lining, etc. The cleaning and polishing qualities of "Selvyt" are well known.

The Doherty Motor Accessories Company, Limited, made an effective display of the productions of their well-equipped works. In order to meet the wishes of manufacturers in making designs as distinctive as possible, the company cater rather for developing the ideas of makers than making standard designs. Their productions were therefore to be seen on many other stands as well as on their own. The special feature of their display was a new patent transverse tubular radiator. In this latest type of Doherty radiator the effective appearance of the honeycomb pattern has been remembered, but the form of construction has been designed with a view to strength and durability of the parts. The principle of the new tubular radiator, which should give most effective cooling, can be seen from the accompanying illustration Fig. 109. Radiators and bonnets for motor-lorries and cars were in plentiful profusion on the stand, the bonnets being of good outline and supplied in planished steel, aluminium, or tinned steel, the fittings being of brass. In minor matters great care has been taken, and the clips are of a substantial character, entirely preventing the chattering which was a conspicuous feature of the bonnets of other days. Petrol and lubricating tanks, radiators for fore-carriages, cycle tanks, silencers, etc., were also on view. Bucket and semi-bucket seats were on the stand, and in fore-carriages the Doherty Company has brought out a capital design in metal. The frame is of light iron with aluminium panelling and bucket seat. The ease with which the carriage can be cleaned, together with its neat outline and good workmanship, are factors which should contribute to its popularity.

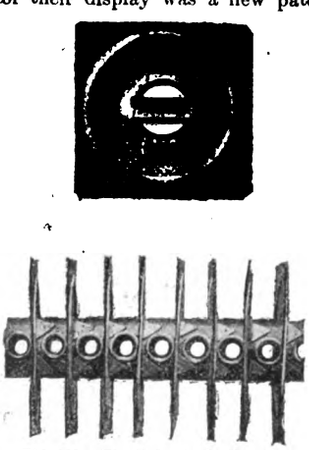

Fig. 109.—The Doherty Radiator.

A long range of tools and machines for motor-car makers, repairers, and the like, comprised the display made by Messrs. C. W. Burton, Griffiths and Co., these including the "Gisholt" combination turret lathe, complete with quick power moving device, one turret and standard set of tools; the "Gisholt" universal lathe and planer tool grinder, a 3 ft. arm "Fosdick" radial drilling machine, a "Lodge and Shipley" lathe, fitted with a quick change gear device; 20 in. "Burton" universal disc grinders, automatic triple action chucking machines, universal grinding and milling machines, crank shapers, cutter grinders, &c.

The Imre Engineering Company displayed the "Universal" silencer for petrol motor-cars and cycles, of which an illustrated description was given in the *Journal* of Jan. 23rd last. The silencer is designed on entirely original lines, the basis of which is the reduction of the exhaust gases from maximum to almost minimum pressure the first journey, through the continued rapid and sudden expansion of the gases as they emerge from each consecutive globe of the series; then on the second or return journey thoroughly cool and reduce the gases to the minimum of pressure and consequent silence at exit by passing them through grooves cut in globes at point of contact with outer cylindrical casing and continued expansion in the various chambers after the streams of gases thus formed enter therein, until final discharge to atmosphere through series of holes in end cap.

Excellent specimens of coachbuilding were shown by Mr. W. Vincent, whose place at Reading is familiar to motorists in the Thames Valley. In addition to motor-car bodies of the tonneau and Roi des Belges type, Mr. Vincent is making a special feature of those with side doors, and also exhibited a good collection of artillery wheels.

Messrs. Grose, Limited, showed their non-skidding and puncture-proof bands, in which the tread of a chrome leather band is fitted with a steel-studded strip. A neat appearance is secured by the leather being formed into the exact curve of the cover it is intended for.

Waterproof garments were shown by Abbotts, whose long experience in connection with costumes for yachting men has given them practical knowledge of the requirements of sportsmen generally that is finding good demonstration in their motoring department. They have a wide range of oilskins for marine motoring, and for motor-cyclists have brought out a new "Combination" coat of good design and workmanship. But their exhibit was by no means confined to leather clothing and the like; they also showed a variety of rubber goods, including mats for the floors of cars, motor air cushions, car covers, leather leggings, and other of their productions in this line.

From the Horn Hill Works, Lowestoft, came a motor-boat, shown by the Durrant's Motors, Limited, who are making a special feature of motors for boats, launches, etc.

Storage batteries were exhibited by the British Steam Traction Syndicate, Limited. For the B.S.T. dry storage battery it is claimed that it can be placed in any position, and that the plates can be charged at an unusually high rate. The absorbent electrolyte is prepared by a special process, which, when placed between the plates, protects the active material from becoming disintegrated and detached. The Syndicate has also brought out a combination battery and lamp for use in petrol stores and motor-houses. The convenient form of this will be apparent from Fig. 110.

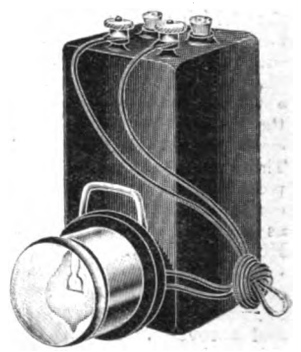

Fig. 110.—The B. S. T. Battery & Lamp.

Tyre exhibits included those of the Clipper Pneumatic Tyre Company, Limited, who showed the Clipper-Michelin, the Clipper-Continental, and the Clipper motor-tyres; the Dunlop Pneumatic Tyre, Limited, who, in addition to the tyres bearing their familiar name, had a range of waterproof motor clothing, motor-car aprons and coverings, and similar goods, in which they have an extensive branch. The Goodyear tyres were on the stand of Mr. A. C. Hills, which also contained a 18-22-h.p. Mercedes car and a two-cylinder Clement car.

Messrs. W. Glover and Sons, Limited, who are giving heed to the development of heavy motor traffic, as well as to the requirements of those who possess cars of lesser power, showed the combination roadside tool described and illustrated in the *Journal* of September 12th last. This can be arranged as a jack, a drill, or a vice—a triple combination that cannot fail to be of service to motorists when trouble befalls them on the roadside. Considerable ingenuity has been displayed in the design and construction of the device.

The Excelsior motor-bicycles and fore carriages were shown by Messrs. Bayliss, Thomas and Co., Limited, who are making them with engines of 2¼-h.p., 3-h.p., 3½-h.p., and 4-h.p. Special interest was shown in the 4-h.p. motor-bicycle and fore-carriage. The cylinder is 90 m. by 96 m., with extra wide bearings, and the engine is of the water-cooled type. The frame is of weldless steel tubing, the engine being in the well-known "Excelsior" position. A Magna Lincona belt is fitted, the carburettor being of the Longuemare spray type, or a specially designed surface carburettor is provided if desired. The 4-h.p. Excelsior motor-bicycle is also supplied with a free engine and two-speed gear, making it one of the most powerful and efficient machines of its class on the market.

At the stand of the Hyde Rubber Works, Limited, was the "Grappler" motor tyre, which has long been before the motoring public. The patents in connection with this are now the property of a syndicate, whose knowledge of the value of the tyre induced them to acquire them at a heavy cost, and to lay down a plant with which to cope with the manufacture. At the same time a most beneficial arrangement has been entered into with the Hyde Rubber Works, Limited, of Woodley, whereby the latter supplies the syndicate with all materials necessary for the manufacture, and places at its disposal their lengthy experience as rubber specialists. The method of attachment is a great point in favour of this tyre, making it practically impossible for the tyre to blow off the rim or the creep when at work.

Messrs. John Child Meredith had a large and representative

Digitized by Google

collection of the specialities with which their name and their trade-mark G. O. M. is identified. These included lamps of every kind, carburettors, inlet and exhaust valves, jacks and tools, G. O. M. coils and accumulators, and a new pattern of special contact breaker of the wipe class. Another novelty on their stand was a new toggle switch for fixing to the handle bars of motor-cycles.

Messrs. Henry Whitlock, Ltd., had a conspicuous display in the Main Hall, consisting of Whitlock-Aster cars of 10, 12, and 20-h.p. These are fitted with the new Aster engine with mechanical valves, and at once struck the attention of visitors by the excellence of the coach work. Phaeton and tonneau bodies were shown luxuriously upholstered and characterised by fine workmanship throughout.

At the stand of the Electric Ignition Company was a plentiful assortment of the E. I. C. sparking coils, contact breakers, accumulators, switches, sparking plugs, testing sets, etc. There was also a working exhibit of the "Lodge" coil—an improved system of high tension ignition patented by Sir Oliver and Mr. Alec M. Lodge. As there are always, in the "Lodge" coils, two sparks occurring practically simultaneously, the spark passing at an adjustable gap inside the case has been named the "A spark"; while the spark at the plug used for igniting the charge in the cylinder is known as the "B spark." It is, perhaps, of interest to note that the A spark is the spark used in ordinary coils, and which is so susceptible to short circuits; but, by the "Lodge" arrangement the A spark is shut up in the case of the coil, and is thereby completely protected. The B spark, which gives the charge, is bound to occur in unison with the A spark. By this system of ignition the chances of misfiring are practically wholly eliminated. It may also be added that the only changes needful for this increased reliability are embodied in the coil itself, so that all fittings and connections in use with ordinary coils are used in the same way exactly with the "Lodge" ignition.

Messrs. Geipel and Lange, at their stand in the Arcade, displayed the Vulcan speed indicator, an electrical device for indicating the speed at any moment, without employing moving shafts, bevel wheels, or friction driving. It consists of a magneto driven off one of the wheels and a hot-wire voltmeter connected by means of a flexible wire, so forming the speed indicator. The dial is calibrated to indicate from five to forty-five miles per hour. The magneto is small, weighs only 1½ lb., and is arranged to be fixed on the horn of the front wheel, being driven by a rubber band from a pulley fixed on the wheel. The magneto is entirely waterproof, and the whole design is such as to obviate the necessity for attention. The indicators are made in two sizes—one having a 2 in. dial, for fixing on the steering wheel, and one, with 4 in. dial, for fixing on the dashboard. Another interesting device exhibited was a distance recorder or odometer, giving a record of the distance travelled, and arranged to be fitted on the hub cap of the front wheel of any make of car. It consists of an aluminium box, 4 in. diameter, furnished with a neck which is fitted to the hub cap in a simple manner. The whole of the apparatus revolves with the wheel, whilst a centre shaft is attached by a spring against the axle of the wheel, which is made immovable as the wheel revolves. The body of the recorder consequently revolves, whilst the centre axle remains fixed. The result is, that the internal mechanism operates the indicating portion, which shows at any moment the exact distance travelled since it was fixed. The dials are of the step-by-step

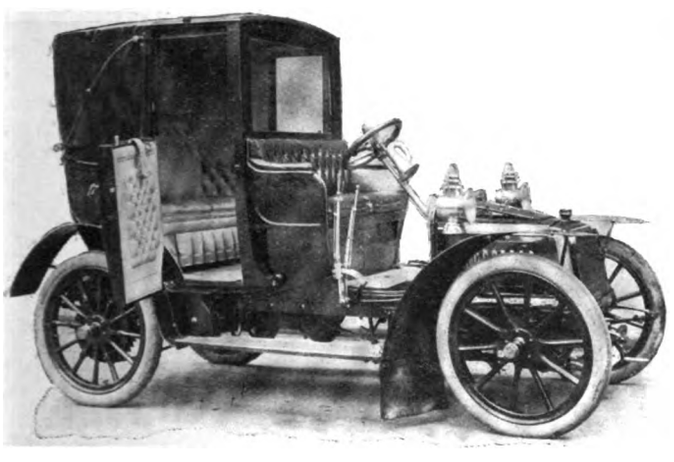

Fig. 111.—A Panhard three-cylinder Landaulet, exhibited at the recent Agricultural Hall Show by Messrs. J. E. Hutton, Ltd.

type, indicating up to 10,000 miles, the lowest dial being graduated in 1-16ths. In addition to the moving dials there is a series of indicators arranged so that a record can be made at any moment of the exact state of the recording dials, enabling the driver at a glance to ascertain the exact distance travelled from the time that the pointers of the indicators were last set. Thus a record of the distance travelled per trip may be obtained. Other exhibits of this firm included the Pyros unbreakable sparking plugs, induction coils, and an "Automatic" accumulator, which does not work when on open circuit, and the Vulcan auto-trembler, suitable for one, two, and four cylinders. The latter, as is now fairly well known, consists of a small high-speed trembler arranged to go in series with a non-trembling coil, thus converting it into a high-speed trembling coil, with its attendant advantages of easy starting under all conditions and perfect firing at every speed.

A good show of lamps, including the "Otto" head light and the "Otto" motor-cycle lamp, was made by Mr. A. Rothschild, who sought to interest the trade in the many good points of some recent introductions in this line.

The Electric Battery Company made a good show of accumulators (Fig. 112) for electric ignition, electric ignition apparatus, including coils, with or without trembler, voltmeters, wipe contact breakers, test lamps, etc. A feature was made of the "Sparkwell" mica plug. This is provided with platinum points, and is claimed to be indestructible and soot proof—two important considerations to motorists.

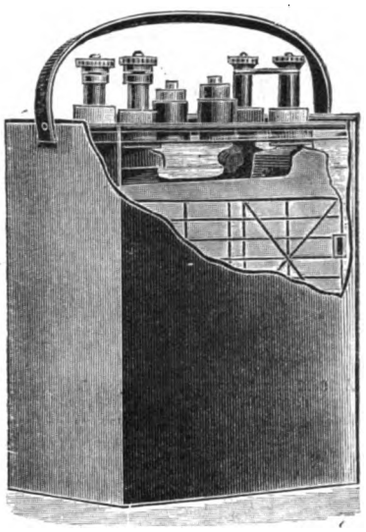

Fig. 112.

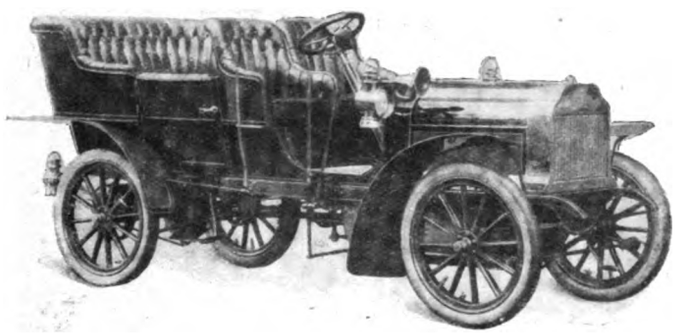
Messrs. J. King and Co. had an interesting display, including a sea-going launch, with a 6-h.p. twin-cylinder motor. This firm are becoming well identified with motor boats, dinghies, etc., and their motor has some good points of interest to the growing number of sportsmen going in for marine motoring. The Lozier Motor Company also had a collection of motors and motor launches fitted with their own well-known engine. In the Arcade Messrs. Lister and Sons drew attention to the merits of their "Popular" motor for motor launches, of which they showed an excellent specimen.

On the stand of the Motor Manufacturing Company, Limited, space was found for the Gratze-Oades speed indicator and speed-limit alarm—an ingenious device which was explained by the inventor, Mr. R. V. Gratze. By the method of construction adopted, the deflecting needle is not connected with the rotary portion of the instrument, with the result that no amount of vibration can affect the accuracy of the reading. Steel ball bearings are provided for the rotating part of the device. A novelty in connection with this indicator is the speed limit alarm, which can be set at any required speed. When the speed at which it is set to ring is reached, the pointer rubs over the raised pip on the dial, forming a metallic connection and ringing the alarm. There is a positive drive and connection to transmit the rotary motion by a toothed wheel or worm thread through a jointed or flexible shaft. In advocacy of his ingenious speed indicator, the inventor points out that the instrument indicates the speed the car is travelling at, the maximum speed he has attained, the distance covered, and the warning that a certain speed has already been reached—the latter being a most important consideration in view of the activity of the police in various districts.

The "Max" accumulator on the stand of the Max Accumulator Company attracted notice by its lightness and its reputation for efficiency. It is characterised by a peculiar form of cylindrical electrodes, each electrode being formed of a core of antimoniated lead wire, surrounded by active material, protected by an indestructible covering or braiding of asbestos yarn, similar to that of a cable, and mechanically placed around the electrodes. The disintegration and shedding of the active material which it completely and totally encloses is thus prevented. It can neither leave its support, nor cause short-circuits, even when the electrodes are in contact upon their whole length. In the ignition accumulators the elements are enclosed in cells of transparent celluloid, so that the level of the liquid may be easily checked. Special stoppers are provided to avoid the projection of the liquid, although it permits the escape of the gas evolved during the charge. Batteries for carriage lighting, garages, etc., were also shown on this stand.

The "Calvert" water and air engines, in various powers, were shown by the Stoke Newington Motor Company, who had also a varied assortment of gears, coils, tanks, axles, parts, etc.

At the annual meeting of the General Accident Assurance Corporation, Limited, the chairman said that 1903 had been the best year experienced by the company. To this development the motor department controlled by Mr. A. Nixon has undoubtedly played its part.



The Kensington Garage, Limited, has been registered with a capital of £2,000 to carry on the business of garage proprietors, manufacturers of, dealers in, and letters to hire of motor-cars, etc. The first directors are Messrs. J. L. Symon and F. King. Mr. Sessions is the manager.

HERE AND THERE.

AT Hassett Street, Bedford, Messrs. Cruse and Son are adding to their engineering works a motor-car department.

THE next meeting of the General Committee of the Motor Union will be held at 119, Piccadilly, London, W., on Monday next at 5 p.m.

A 10-12 h.p. Argyll fitted with side entrances. The car has a wheel base of 8 ft.; the tonneau is very roomy, and luggage can easily be carried between the doors in the event of the owner going on tour.

BY an Army Order just issued a new class of officers is added to the Army Service Corps with the title of Inspectors of Mechanical Transport.

A DEPARTMENT for the repair of accumulators has been opened by Messrs. J. C. Fuller and Son at their Woodland Works, Wick Lane, Bow, E.

THE Royal Assent has been given to the Bill authorising the eliminating trials of the British cars entered for the Gordon Bennett race to be held in the Isle of Man.

MISS K. D'ESTERRE-HUGHES, the secretary of the Ladies' Automobile Club, will be glad if all communications will now be addressed to Claridge's Hotel, Brook Street, W.

THE Velox Motor Manufacturing Company, Limited, has been registered with a capital of £2,000 to adopt an agreement with the London Pioneer Syndicate, Limited, to manufacture and deal in motors, etc.

ABOUT two-thirds of the course of the Isle of Man eliminating trials will be laid with Westrumite, which will also be used on the roads in the neighbourhood of the Punchestown racecourse during the King's visit to Ireland.

THE Auto-Van Supply Association, Limited, has been registered with a capital of £5,000 to buy and sell self-propelled vehicles of all kinds, and all tools, accessories, and plant used in connection with the manufacture, repairing, storing, cleaning, and using of such vehicles.

A TRADE list of their motor masks, goggles, hoods, etc., comes from Messrs. W. Stephens and Company, an English firm well able to undertake repairs to all descriptions of goggles, which they make a special feature of their business. Motor lamp covers, the "Handy" strap, a washable saddle cover and other minor accessories, are among other specialities of this City house.

MESSRS. PHILIPP AND COMPANY forward a copy of their new catalogue of motor-car fittings, which will be of value as well as of interest to automobile manufacturers. Among the special features of these lists we notice a large selection of lubricators, including many adopted by the leading makers. A wide range of hand steering-wheels in mahogany, ash, or oak, with arms of polished phosphor bronze or aluminium, is also illustrated. As intimated in our report of this firm's stand at the Agricultural Hall Show, they are agents for Messrs. Lloyd and Plaister, whose British-made motor they are placing upon the market. Messrs. Philipp and Company also represent Messrs. Malicet and Blin, whose speed gears are already well known in this country

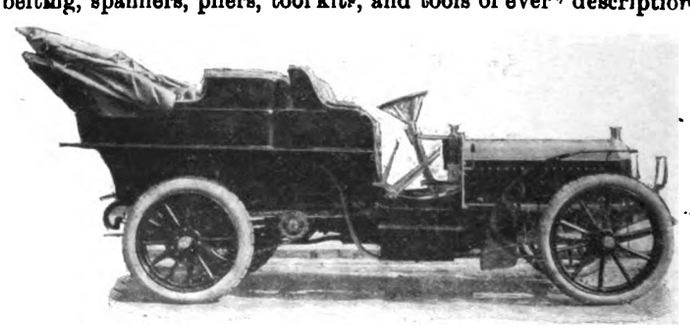
A MOTOR-CAR is like the human body. Even the soundest will not always withstand over-exertion and habitual misuse.

WE learn that Mr. T. Underwood has resigned his position as sales manager of the Motor Manufacturing Company, Limited, an appointment he has held for some years past.

FEBRUARY proved to be a good month as regards the exports of motor-cars and parts from the United States, the values amounting to £25,448 as against £12,644 in the same month a year ago.

ARRANGEMENTS have now been completed whereby the batteries of electric automobiles may be recharged at the generating station of the Bournemouth and Poole Electricity Supply Company at Bargates, Christchurch.

MR ALDEN SAMPSON, of Pittsfield, Mass., has notified the Automobile Club of America that he will be unable to get his racer completed in time for the Gordon Bennett contest, and has requested that his entry be cancelled.



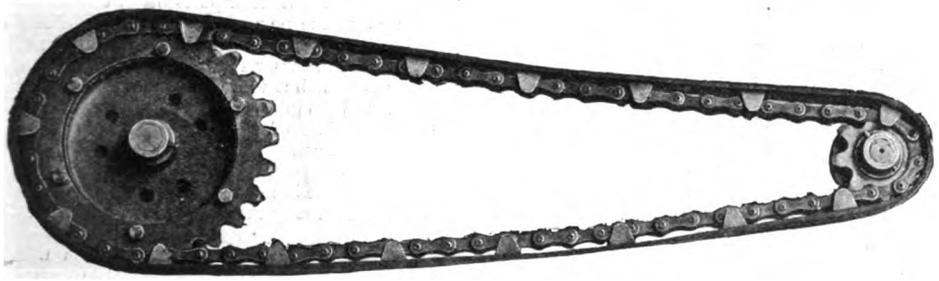
THE twelfth "James Forrest" lecture will be delivered at the Institution of Civil Engineers, Great George Street, Westminster, by Mr. Dugald Clerk, M. Inst. C.E., on Thursday, the 21st inst., the subject being "Internal Combustion Engines."

MESSRS. RENNIE AND PROSSER, LIMITED, have just opened new repair works and free garage at 60, North Wallace Street, Parliamentary Road, Glasgow. The new works, which cover an area of 2,000 square yards, are centrally situated, and equipped with up-to-date plant.

PRINCE and Princess Henry of Prussia arrived in London on Saturday last. Accompanied by Prince Segismund, they drove to the Grosvenor Hotel, but subsequently left there in Prince Louis of Battenberg's motor-car for Radlett, Herts. The Royal visitors are both enthusiastic motorists and have lately acquired a 24-h.p. Benz-Parsifal car.

MESSRS. JOHN CHILD MEREDITH, LIMITED, have sent us a sample of a new sparking plug they are just introducing. The special feature of the plug is that the porcelain only comes in contact with a very small portion of the metal, which prevents the severe pressure upon the porcelain. The plug, which has an unusually stout central terminal, is supplied in neat wood case.

MESSRS. W. H. WILLCOX AND COMPANY, LIMITED, have sent us a copy of the new catalogue of motor-car accessories they have just issued. The list gives particulars of the wide and varied assortment of articles supplied by this firm, including lubricating oils, semi-rotary water circulating pumps, Penberthy automobile injectors, X-L water raisers, wire bound hose, "Richardson" boiler feed pump, lubricators, oil cans, lifting jacks, belting, spanners, pliers, tool kits, and tools of every description.



The Rt Hon. A. J. Balfou new six-cylinder Napier Car with Cape-cart hood. The body is exceedingly roomy, holding six people in the back portion and carrying eight in all.

A COURSE of lectures on electric vehicles was begun in the Y.M.C.A. evening institute, Boston, U.S.A., on March 1 with a lecture on the practicability, cost and efficiency of "Electricity as a Motor Power in Vehicles." The second lecture, given on the 8th inst., dealt with "Storage or Secondary Battery"; the third, on the 23rd inst., dealt with the subject of the "Application of Power to Wheels," and the fourth with "Charging Outfits."

Digitized by Google

THE accompanying illustration shows the "Little Giant" dirt guard and grease retainer for use on the driving chains of motor-cars which has lately been brought out by the Blackfriars Motor and Engineering Works, Stamford. Every motorist knows that of all the parts that go to the make up of the whole, there is none that is left so exposed to dirt and dust, and so difficult to keep properly lubricated, as the chain. If it were not for this, the life of driving chains, would probably be three times as long as at present. The excessive wear that takes place is due to the grit that finds its way in between the links

and rivets; in addition, the grease and oil which is placed upon the chain for lubricating purposes is quickly thrown off. The protector illustrated herewith consists of a specially constructed belt of a greater width than the chain; clips attached at intervals keeping it in position upon the latter. The device, which can be quickly fitted, prevents mud and dust being thrown up on to the chain, and also prevents the lubricant being thrown off.

THE West London Motor Company, Limited, Hammersmith, have been appointed London agents for the "Clyde" cars.

THE Pytchley Autocar Company, of Bradshaw Street, Northampton, have just enlarged their premises. They now have 450 square yards of showrooms and repair shops in the town, and have now the sole agency for the Midlands for Fiat cars.

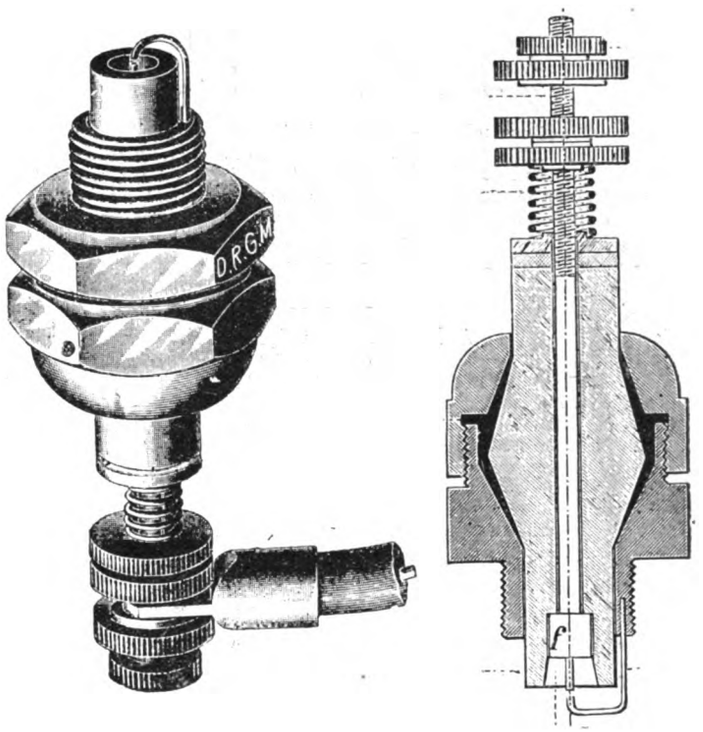
THE Chloride Electrical Storage Company, Limited, of Clifton Junction, Manchester, have sent us a booklet descriptive of the "Exide" accumulators they are introducing into this country for use on electrical motor-cars. The "Exide" battery, which is a popular type in America for such work, is claimed to have a very high output per unit of weight without unduly sacrificing mechanical stability and life.

STIRLING'S MOTOR CONSTRUCTION COMPANY (1900), Limited, write us from their boathouse at Strawberry Vale as follows:—In clearing out the van which brought us our goods back from the show at the Agricultural Hall our storekeeper reports that there is a parcel of fittings which do not belong to us. They appear to be brass supports for showing hats or caps, and we thought you might be able to trace the owner by giving the matter a note in the *Journal*. We notice on examining them there are three dozen that bear the name F. McIlvenna and Co., 79, Wood Street, E.C., stamped on."

FROM Messrs. C. W. Burton, Griffiths and Company comes an abridged pocket edition of their catalogue of modern machine tools and workshop appliances. This will be of value to makers as well as repairers of cars, and, in fact, to all using machinery of any kind. Among the machines illustrated and described are various automatic appliances, boring and drilling machines, grinding and milling machines, lathes, saws, and saw benches, twist drills, wood-working machinery, tool grinders, and, in fact, everything which comes under the head of machine tools. Various minor appliances are also described. A separate publication is devoted to engineers' small tools, which have secured universal recognition because of their accuracy and quality. Gauges, drills, vices, etc., find illustration here, while a third catalogue of interest is a treatise on grinding, explanatory of the merits of the Burton disc grinder. Interested readers will be able to obtain any of these useful booklets from Messrs. Burton, Griffiths and Company, Ludgate Square, London, E.C.

MESSRS. THOMAS SHAW, Ltd., of Reform Street, Dundee, are establishing a large motor garage in Ward Road, in that city.

AT the recent Exhibition Automobiles de Luxe took advantage of the occasion to call attention to their system of letting cars out on hire.



MESSRS HUNTLEY AND PALMER'S biscuit works at Reading are protected from fire by a petrol motor fire-boat in addition to their ordinary appliances.

VIRGINIA BEACH having been found unsatisfactory for speed trials, the eliminating trials for the American team for the Gordon Bennett race will in all probability be held on the Ormonde Beach, in Florida. As there are only three entries for the American team, it would not be absolutely necessary to hold an eliminating race, but we are informed that the Automobile Club of America wishes to convince itself of the fitness of the vehicles chosen to represent it in the race.

AT 20, Danvers Street, Chelsea, S.W., the Grosvenor Engineering Works have a large inspection pit and a competent staff of mechanics who have extensive experience in motor-car repairs. More than a hundred cars passed through the works in the last twelve months.

MESSRS. FLEMING, BIRKBY, AND GOODALL, LIMITED, of Halifax, have just issued a very complete catalogue of their specialities in the way of belting, belt fasteners, pulleys, hose, etc. The list is conveniently arranged in sections, and a number of pages are devoted to useful hints regarding belt drives.

THE ignition plug illustrated herewith in general view and in section is the production of a German firm, the Rapid Accumulatorem und Motorenwerke, of Schoneberg, Berlin. The

plug is notable for apparently excellent insulation of the terminals, and the provision made to prevent fracture of the porcelain core by unequal expansion. The porcelain core is of double conical shape at its middle part, the conical surfaces being surrounded by asbestos. The inner rod is held in place by means of a spring bearing against a nut secured with a lock nut. The insulating core projects a considerable distance beyond the metallic shell at the inner end.

CORRESPONDENCE.

STEAM CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—I was hoping my letter to the *Journal* would be the means of getting further information from "Steamer" *re* the heating of his car by exhausting into the water-tank the whole of the exhaust steam. I have experimented on most things with the Locomobile, and added many improvements, and any information for the benefit of motorists I am pleased to give. With your permission, I give particulars for cooling of the seats, requested by "Another Steamer." I use a square pattern front condenser and attach a tin taper funnel on the bottom, and secure to condenser by the screws fitted on either side at bottom with iron angle straps. The inlet of this air-funnel is 26 inches by 3½ inches, made taper as shown, and connected with 1¼-inch rubber hose to a tin nozzle with an outlet 10 inches by ⅛ inch; the pipe is placed by the side of water-heater (nozzle on top), and produces a current of cold air under the seat when the car is travelling. The whole job can be done for 15s.

I run two Locomobiles—a No. 2 and a larger pattern. The latter I have had fitted to burn paraffin with the usual petrol burner, by Messrs. Morriss, 82, Stroud Green Road, Finsbury Park. The principle of it is this—it lights up with a pilot lamp (on paraffin); after 20 lbs. of steam the main burner is turned on and a steam jet; the fuel and steam supply works automatically from the usual arrangement on these cars; a pressure of 250 lbs. steam can be reached in twenty minutes.—Yours truly,

Vapeur.

A MYSTERIOUS NOISE.

To the Editor of *The Motor-Car Journal*.

Sir,—Replying to "Dermatine's" letter in the last issue, the clinking noise is no doubt caused by the cardan shaft having become worn, and would only be detected when the car is on the top speed, this because the engine is running at a much less speed than when on the lower gear, and, in consequence, would give an uneven transmission, which is overcome when the engine is running at its nominal speed. Having had precisely the same trouble with a small car, I can speak from experience, and think that upon close examination "Dermatine" will find this to be his trouble.—Yours truly,

T. H. S.

To the Editor of *The Motor-Car Journal*.

Sir,—In answer to "Dermatine," in the last issue, I had a similar experience with a 6½-h.p. Aster gear-driven car, and found the reason was that the bolt at the bottom of the change-speed gear lever had worn and worked loosely, so that when on top speed the gear was not quite home. On fitting a fresh bolt the noise was done away with, until it showed signs of wear, when, if out on a run, and the knocking started, I pressed the lever beyond the final notch, and kept it there with right foot when I wanted to keep the top speed in. Perhaps this might be the reason.—Yours truly,

6½-h.p. Aster.

1904 MERCEDES CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—A friend has sent me a cutting of Mr. Weigel's letter on the subject of the nomenclature of the Mercedes cars, and I have taken advantage of my being with Mr. Jellineck at Nice to obtain from him accurate information on this very confused question of the correct horse-power of these well-known cars.

Mr. Weigel states that the cars being put on the market this year by the Cannstatt Works are as follows:—24-28-h.p., 24-32-h.p., 40-45-h.p., and 60-h.p., whilst his informant in Paris declares that the production of 1904 Mercedes at Cannstatt will be of the following types:—24-28-h.p., 40-h.p., and 60-h.p., and that the other types will not be made at Cannstatt. Neither of these statements is accurate, for the Cannstatt Works' description of the cars being turned out this year is as follows:—18-24-h.p., 24-28-h.p., 28-32-h.p., 40-h.p., and 60-h.p., and all these cars are manufactured at what are known as the Cannstatt Works.

Strictly speaking, no Mercedes cars are being actually manufactured at Cannstatt, the original works having been destroyed by fire last June, and not having since been rebuilt. The essential parts of all the pleasure cars are and will be manufactured at the new works at Unter-Turkheim, four miles from Cannstatt, the old works, or what remains of them, being only used for body making, for storing finished cars, and for offices. The Daimler Company have other works near Berlin, but there only heavy launch and lorry motors are manufactured, and no pleasure cars are made by the company there or elsewhere than at Unter-Turkheim.

To make matters perfectly clear, I cannot do better than to give your readers in tabular form the details of the present output of the Daimler Company, which Mr. Jellineck has supplied me with, the same being a copy of a statement made by the Daimler Company themselves, at Cannstatt:—

Works description of Cars.	Type.	Bore mm.	Stroke mm.
18-h.p.	1903	90	120
18	1904	100	130
24-28	1903	105	130
35-40	1903	116	145
60	1904	140	150
28-32	1904	110	140
40-45	1904	120	150

Now as to Mr. Weigel's complaint that dealers are not entitled to call the 18-24-h.p. 1904 an 18-28-h.p. car, I would like to explain how it is that this car, in the contract under which I bought thirty of them, came to be described therein as an 18-24-h.p. car. It is called an 18-h.p. car because it has the same frame and body as was supplied with the 18-22-h.p. car of 1903. It was called 18-24-h.p. because at that time Cannstatt intended to supply a 20-h.p. motor, that is, a motor of 100 mm. bore and 130 stroke, which they estimated would yield 24 effective h.p., whereas on testing the engine it was found that the motor developed fully 28-h.p. and even more. In these circumstances I felt justified in describing the car as an 18-28-h.p. car; in the same way as Mr. Weigel in his letter describes the 40-h.p. car which gives 45 on the brake as a 45-h.p. car. To me and to any ordinary person it appears reasonable that if a car develops on the brake a certain h.p., one is entitled to call it by the h.p. developed, and surely the most important thing for the buyer is not to know what is the nominal h.p., but to know the actual brake h.p. which can be given, and to see that he gets it.—Yours faithfully,

C. Harrington Moore.

QUERIES *RE* WOLSELEY CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—Can any of your readers enlighten me upon the following experience? My 7½-h.p. Wolseley on a long day's run will vary greatly in "life." The petrol conditions are practically equal, no additional spirit being needed under, say, 120 miles. The air inlet is always full open, and, to utilise top speed to its full capacity, inlet springs are lightly adjusted. The car runs far better in the after part of the day, even at this time of year, and, in the face of a stiff dry wind, travels splendidly with full load.

It seems to me that an additional air inlet to the air bottle, controllable from the dash-board, might be of use. One thing I am quite sure of, viz., that Pratt's "B," although usable, makes a poor mixture, and that Bowley's "A" is better than Pratt's "A," this being shown not in running alone, but also by gravity test. Does anyone know anything of the new Wolseley automatic carburettor, and is their new silencer a great saver of power?—Yours truly,

Jehunior.

[This varying in life is undoubtedly due to want of air, but this can easily be tested by starting the engine and turning off the petrol supply from the tank. If more air is required, the engine will increase in speed as the petrol level gets lower. In any case there would be no harm done in adding an auxiliary airway controllable from the seat, which could easily be shut off if found unnecessary. In our own experience we have found no difference in the running of the car either with A or B spirit.]

THE TIME FOR OVERHAULING.

To the Editor of *The Motor-Car Journal*.

Sir,—Like nearly all mortals, motorists are prone to procrastinate—to put off until some other day the work that should be done to-day. Spring is upon us, and if not already done the work of overhauling and putting in running order one's car ready for the coming season should be put in hand without delay. Such work will have to be done, and it is simply a question of having it done now, when repairers have plenty of time, or of rushing it through a few weeks hence, when pleasant, sunny days tempt the motorist forth and every shop is crowded with urgent

Digitized by Google

work. There are many motorists who will say that their cars do not require overhauling; that they are as ready to run now as they were last year. This is true in a measure, but they would give vastly better service if they were gone over by competent hands and put in the pink of condition. This is especially essential with cars that have been laid up for the winter. All machinery is the worse for disuse. Dust and dirt penetrate to the working parts, however great the efforts to exclude them, and should be carefully removed. No machinery will run long without requiring some adjustment, no matter how slight, and the parts which have been cleaned, lubricated and adjusted will perform their allotted functions in a manner infinitely superior to machinery which has been left to itself, even although the latter has nothing really wrong with it.

Again, when cars are "laid up" they are usually dismantled to some extent. The tyres are removed or the wheel jacked up, the batteries disconnected, the cushions taken out, the bright parts vaselined and the entire car covered with sheeting or similarly protected. As every one knows, it is much easier to take down than to set up; and time and opportunity and some skill are ingredients indispensable if a good job is to be made of the latter process. Yet it is usually put off until the last minute, and then hurried through in a careless fashion hardly conducive to the best results. Many motorists like to undertake the "setting up" process themselves, finding pleasure in constructive work of this sort. There are many others who, either from inability or disinclination, do not care to undertake this, and they throng the repair shops just when the opening season rush is greatest. Therefore I venture to suggest to those motorists who intend to have their car overhauled for the coming season that now is the time to put the work in hand.—Your truly,

L. P. Oliver.

THE EVOLUTION OF SPEED.

To the Editor of *The Motor-Car Journal*.

Sir,—This year we shall probably see more cars and motor-cyclists on the road than in any previous season. Many at this moment will be hesitating what their particular mount of 1904 is to be. May I, as a motorist of longer standing, perhaps, than most drivers and riders, venture to point out what, in my humble opinion, so many people lose sight of, viz., the necessity of increased horse power for those who are no longer feather weights?

When I commenced hunting in Leicestershire, more than thirty years ago, a ten stone horse suited my requirements perfectly. Now, alas, owing to Anno Domini, and a certain amount of embonpoint, I have to purchase fourteen stone hunters instead. With a bicycle and a car I maintain the case is identical. If the rider does not want his mount to halt beneath him when ascending rising ground, he must always have a bit in hand on the flat.

I began motoring with a Benz car of 3½-h.p.; my second car, an 8-h.p. Napier, distanced all other English competitors in the 1,000 miles Club run to Edinburgh and back, over which we took three weeks! My third was a 15-h.p., and I am now anxiously awaiting the delivery of a new 30-h.p. six cylinder car.

As a motor-cyclist, evolution has carried me forward in precisely the same progressive fashion. My 1¾ became a 2¾, and I am now the possessor of a Clyde motor-bike that develops an easy 4 on the brake. What is the result? Instead of having to propel, with faltering steps and perspiring brow, an underhorsed machine up wearisome inclines, we now glide gracefully to their summits, without pedalling and without anxiety, no matter how steep the ascent. As to danger, with proper exhaust control on the handle bar, there is absolutely nothing to fear. In any serious emergency, speed by means of this lever can be immediately reduced. In traffic you can crawl behind the slowest growler, leisurely following in his wake.—Yours truly,

E. Kennard.

RESISTANCE IN BATTERY CHARGING.

To the Editor of *The Motor-Car Journal*.

Sir,—Could you inform me if it requires any resistance, and if so how much, to charge a 4 volt 15 ampere accumulator from a 6 volt 40 ampere one.—Yours truly,

D.

[A 4 volt accumulator requires five volts to charge it, therefore it will be necessary to use sufficient resistance in series to absorb 1 volt of the pressure given by the 40 ampere accumulator. Assuming that "D." wishes to pass one ampere through the accumulator to be charged, he will require five volts more or less at its terminals, according to the voltage which the accumulator is giving itself, as the current is produced by the difference in voltage between the accumulator being charged and the accumulator charging. Therefore it is not possible to state exactly how much resistance is necessary, but if 1½ ohm of resistance is provided, this can be cut in or out of the circuit as required. Thin iron wire rolled into a coil or German silver wire make suitable resistances. On no account attempt to charge the accumulator with the whole of the six volts available, as, though it may appear that an increase of one volt will not make a great difference, seeing that it is only an increase of 20 per cent. of the whole amount, it should be remembered that the acting voltage is only the difference between the two accumulators, so that if one gives 4½ volts when being charged, and the other gives five volts, the actual voltage being employed to charge is half a volt, and therefore if the whole six volts is used the acting voltage is increased to three times its previous amount. This point is a very important one to note in charging accumulators, as the excess of charging current may ruin the plates unless due care is taken to regulate the voltage of the charging battery. It is advisable to employ an ampere-meter as a guide to the proper regulation of the resistance. About fourteen feet of German silver wire, No. 20 gauge, will give a resistance of 1½ ohms.]

MOTORISTS, BEWARE OF ENFIELD.

To the Editor of *The Motor-Car Journal*.

Sir,—I have to-day been summoned before the Enfield bench of magistrates for driving a car beyond a speed of twenty miles an hour. In the evidence given I elicited from the first constable who gave evidence that he was quite inexperienced in timing a motor-car, as it was practically his first attempt at timing. He gave in evidence that I covered 352 yards (one-fifth of a mile), in 22 seconds, or at the rate of 32½ miles per hour. The second constable to give evidence, who appears to have timed me over the first mark, swore I was covering only twenty-eight miles per hour; he also said, on my cross-examining him, that his method of timing was to see the car over the first mark, to wave a white signal to the constable at the second mark, and then walk along the road to see the time the car passed the second mark, when he stopped his watch, he being at this moment at least 280 yards from the mark he was trying to see. I submitted to the bench that it was impossible to time correctly on such a system. Mr. Lord, the chairman of the bench, then said, if he had his way he would limit all cars to twelve miles per hour, and any other case that came before him in future which was proved he should impose the full penalty of £10. I was fined £5, and my licence endorsed. I trust all motorists will keep clear of Enfield.—Yours truly,

H. G. Stacey.

A White Steam Car by the S.a.

MOTOR RACING ON ENGLISH SHORES.

To the Editor of *The Motor-Car Journal*.

Sir,—Although I should be very loth to oppose any scheme put forward for the good of the motoring world, I should be extremely sorry to see "Yorkshireman's" proposal, as set forth in your issue of the 25th March, considered seriously.

Filey is by no means the deserted place one might be led to imagine from his description, and I can conceive no worse fate that could befall it than the adoption of such a scheme as his. I feel sure that the inhabitants themselves would strongly object to their splendid sands being made the scene of motor racing. For the matter of that, I do not know any part of our English shores suitable for the purpose. The conditions which obtain on the continent of America are far different to those over here, and there are many things that our American cousins can do there with impunity that are impossible here.

Filey is not an inaccessible place by road, nor is there any lack of accommodation there, but take away the use of the sands and you rob Filey of one of its great attractions.

There is a site, however, which has been under the consideration of the Automobile Club of G.B.I., and which is an ideal one for motor speed contests, and it is a matter of great regret that it has not been acquired. I refer to the land south-west of Clacton-on-Sea, in Essex. There one of the finest tracks imaginable could be made, with the additional advantage of having a depth of water close at hand suitable for carrying out motor-boat races. The distance from London is only seventy miles, with a splendid main road all the way. Further, it is accessible from the Midlands by good roads, and the town possesses ample accommodation for motorists. May I conclude with the hope that we shall never see motor-racing on our English shores, as any such innovation would drive away more people from a place than it would

Digitized by Google

attract to it. The sands are the children's playgrounds and should remain as such. Let us have a track near the shore, if you like, but it must be on private grounds.—Yours truly,

F. 110.

THE RULE OF THE ROAD.

To the Editor of *The Motor-Car Journal*.

Sir,—I must apologise for a rather belated communication, as I have been from home, and did not till to-day see Colonel Magrath's letter and your favourable comment on it, touching the Rule of the Road. It is a very important subject.

Colonel Magrath and I—old friends—were close companions on the same car all through the great 1,000 miles trial of four years ago. We jogged along in pleasant amity the whole way, and if we had a friendly difference it was on this question only. I see that with his characteristic energy he has been pressing his views on lord and other mayors, and has gained your sympathy. As my view is opposed to his, holding as I do that the change he proposes would be fraught with great danger to the pedestrian, I ask leave to say a word. The pedestrian rule of keeping to the off-side of the road is based on a sound principle, that those on foot should not walk on the part of the road on which fast and dangerous traffic may come on them from behind, but should face the fast traffic coming towards them, as they can best avoid what they can see, and are not required to be constantly looking round in case any vehicle should be about to run them down. The principle is exactly the same as that contained in the rule for men on foot passing along a railway. The order is that they shall walk so as to have approaching traffic in their view, and should step to the right when a train comes into view. Any other rule is necessarily dangerous, as it places the man on foot with his back to what is approaching. If it is desired to test the matter, let anyone who proposes to cross a street where there is considerable traffic keep inclining to his left until he is in the middle of the street, and when in the middle turn and incline to his right. He will find at once that he has good cause to be nervous. On the other hand, if he first inclines to the right and, after reaching the middle, inclines to his left, he sees everything that is approaching, and can easily regulate his action accordingly, having no need to consider anything but what is in front of him.

As I am writing, allow me to congratulate you on your dropping, in your account of the Carnegie motor house, that ridiculous word *garage*. Please consign *chauffeur* and *chassis* to the same limbo.—Yours truly,

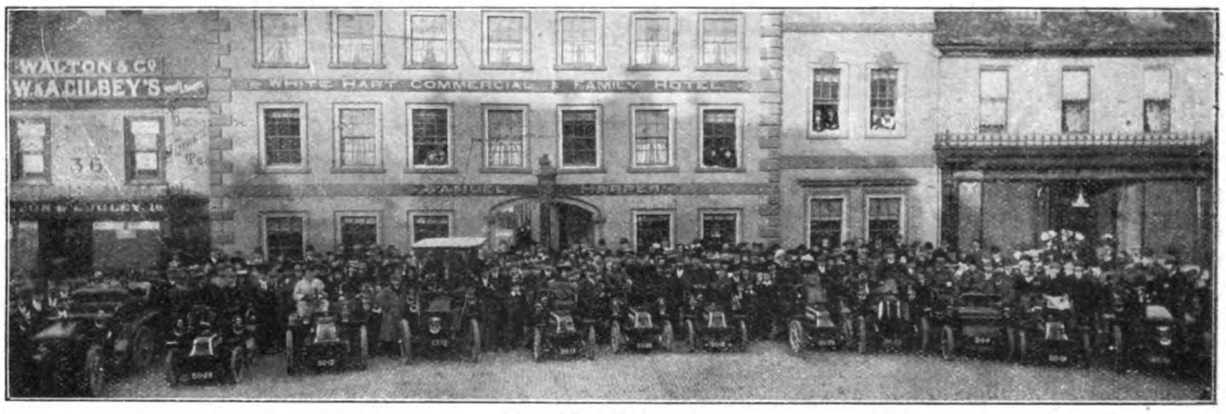
J. H. A. Macdonald.

Books on Motor-Cars.—Mr. E. Cuthbert, who inquires for books on motor-cars, is referred to "The Automobile," by Mr. Paul N. Hasluck, and published by Messrs. Cassell and Co., and to "Motor Vehicles and Motors," by Mr. W. Worby Beaumont (Constable and Co.).

Motor *v.* Delivery Vans.—Replying to Mr. W. J. Magowan, the makers of the combination delivery van and pleasure car illustrated in our issue of the 2nd inst. are the Motor Carrier Syndicate, Cranmer Court, High Street, Clapham, S.W.

Nomenclature.—Mr. B. Aaron writes to suggest the words "Moteer" or "Motician" in place of the term chauffeur.

Steam Wagons.—In reply to Mr. Albert Smith, the makers of the Lancashire steam wagon are the Lancashire Steam Motor Company, Ltd., Leyland, near Preston.



Garage Charges.—A Yorkshire reader asks what would be a fair charge for storing a 10-h.p. car for the year, to include cleaning; also what are the hiring charges for small cars.

Wheel Rims.—A correspondent wishes to know the names of makers of wheel rims. We shall be pleased to hear from readers interested in such work.

CLUBS AND ASSOCIATIONS.

SOUTH LINCOLNSHIRE.

On Easter Monday the South Lincolnshire Motor Club had a run to Spalding. The cars commenced to arrive about three o'clock in the afternoon, making the White Hart Hotel their headquarters. At noon Mr. Arthur Beales left Spalding for Dyke, near Bourne, to fetch Mr. E. M. Pollock, the prospective candidate for the Spalding Division, who arrived at Spalding as the cars were beginning to appear. As they drew up the whole of the vehicles were arranged in line in the White Hart Hotel yard, where they were inspected with evident interest by the people assembled. They were afterwards taken into the Market-place, where they were photographed. The following were amongst the motorists present:—Messrs. W. Garfit, Esq., M.P. (Wolseley), Dr. South, J.P., (Baby Peugeot), Dr. Mason (Baby Peugeot), C. R. Cooke (motor-cycle), H. T. Pilley (Peugeot), Dr. Crompton (Baby Peugeot), Dr. Millar (De Dion), A. W. Holloway (Baby Peugeot), R. Cooke (motor-cycle), F. W. Dennis (Baby Peugeot), A. Beales (Dennis), G. Linnell (Wolseley), C. Holland (Peugeot), R. Holland (Baby Peugeot), H. W. White (motor-cycle), T. W. Mayes (Humberette), A. Green (Baby Peugeot), and F. Richardson (Wolseley). At the tea Dr. Millar occupied the chair, and said how glad he was to see so successful a meeting. Mr. E. M. Pollock said Dr. Millar had asked him to propose a toast, or a sentiment. It was prosperity to the South Lincolnshire Motor Club. The place of the meet, the first of the club, had been well chosen at Spalding, and he went on to refer to the incident recorded elsewhere in our "Comments." In conclusion he declared he had enjoyed the drive from Bourne, his friend Mr. Beales having fetched him in a car, and he was convinced that motoring was a matter in which there must be a good deal of give and take in a district where so many horses were used upon the roads. With these reservations it seemed to him that Lincolnshire was a place where everybody might enjoy the use of the motor-car. They might, therefore, look forward to the speedy development of that club.

The Inaugural Meet of the South Lincolnshire Automobile Club at Spalding.

The following meets have been arranged:—April 28th, Boston; May 14th, Market Deeping; May 23rd, Woodhall Spa; June 2nd, Spilsby; June 16th, Wrangle; June 30th, Kirton. Local motorists intending to join the club should communicate with the hon. sec., Mr. F. Richardson, of Sibsey, Boston.

BERKSHIRE.

The opening meet, reception and gymkhana of the Berkshire Automobile Club will take place at Hall Place, Maidenhead, by invitation of the chairman, Sir Gilbert A. Clayton, on May 28th. Fixtures are also being arranged for June 8th and 25th, July 13th and 30th, and September 14th and 24th.

SCOTTISH CLUB.

The report of the Scottish Automobile Club for the year ended 31st January, 1904, submitted to the annual general meeting of members in the Central Station Hotel, Glasgow, on Tuesday last, gave the membership of the Club as 323, comprised as follows:—Eastern section, 118; Western section, 205. The reports of the sections show the Club to be in a satisfactory financial position, the cash balances on hand as at 31st January last being:—Eastern section, £85 18s.; Western section, £214 12s. 6d. Club meets, competitions, and public trials, as well as meetings for the discussion of subjects relating to automobilism, have been conducted by the Club and its sections during the past year. Several combined meets of both sections took place. Matters affecting the question of affiliation with the Automobile Club of Great Britain and Ireland have been satisfactorily adjusted, and the Club is now represented fully on the committee of the Motor Union. Matters arising out of the Motor Car Act, 1903, have received a large amount of consideration at the hands of the General Council during the past year. Up to the present no roads have been closed, and no ten

Digitized by Google

miles per hour limit has been imposed in Scotland under the provisions of the recent Act. The Council are aware that several public authorities have made recommendations to the Secretary for Scotland in these directions. The General Council believe that, before any action is taken, they and the members of the public interested will have an opportunity of making representations on the subject. The following representatives to the General Council have been elected for next year:—Western Section—Messrs. H. M. Napier, W. H. Kingsbury, Jas. Burns, with the chairman and hon. secretary, *ex officiis*. Eastern—Dr. Wm. Blair, Messrs. Stephen Smith and John Wilson, with Messrs. John Macdonald, chairman, and Geo. Macmillan, hon. secretary, *ex officiis*.

The members of the Eastern Section of the Scottish Automobile Club brought their season to a close by holding a social meeting in the North British Station Hotel, Edinburgh, at which there was an attendance of about eighty ladies and gentlemen. Mr. John Macdonald, chairman of the Section, who presided, said that next year they intended to hold a gymkhana, which they expected would prove one of the most interesting and fashionable functions of the season. On behalf of the members, Mr. Norman Macdonald asked Mr. George Macmillan, the hon. secretary, to accept an address and four pieces of silver plate, as a mark of esteem from the members on the occasion of his forthcoming marriage. Mr. Macmillan, in returning thanks, said he was sure the club would soon be one of the most important and largest in the country.

KENT.

THE second annual general meeting of the Kent Automobile Club was held at Maidstone, on Thursday, the 31st ult., the president, Sir David Salomons, Bart., being in the chair. The balance-sheet, showing a surplus of over £17, was adopted. The financial estimate for the present year showed an available surplus of £157, after deducting the sum of £20 for printing and postage. The somewhat large surplus is accounted for by the fact that the A.C.G.B.I. affiliation fees were paid after October 1st last year, so coming under the rule of the parent club, which states that in such a case no fees shall be payable the following year. Votes of thanks to the president and to Dr. Dowding for his untiring and successful work as honorary secretary were carried unanimously. The first meet of the season will be at Tunbridge Wells to-day (Saturday), the rendezvous being the Mount Ephraim Hotel.

LINCOLNSHIRE.

NOTWITHSTANDING the high wind and the fitful rainstorms of Saturday, and the position of Spilsby, there was a very good attendance of members and friends of the Lincolnshire A. C. at the "Shades," the occasion being the opening of the club. There were several fine cars present, and the ride through the gale had created good appetites. The committee held a meeting, and it was stated that the annual dinner to be held to-day (Saturday) is likely to be a great success.

AUTOMOBILE ACCIDENTS.

THERE has died at the Sutton Hospital a young cyclist, named Parkinson Job, who was admitted suffering from a fracture of the base of the skull and a compound fracture of the left leg, caused by his being run into at Belmont by a motor-car. The driver of the car, Emile Richards, living in Tottenham Court Road, London, was arrested, and is now under remand for causing Job bodily harm by reckless driving.

A SERIOUS motor-car accident occurred on the Hampton Court road, Hampton Wick, on Thursday of last week, to Mr. Higgins, of Court Green, Streatham, who, with his daughter, a lady friend, and a driver named Charles Mercer, were proceeding in a covered steam car towards Kingston, having come from Burcott, near Oxford. The driver was endeavouring to pass an electric tram car and was crossing the metals, which had been recently watered, when one of the solid rubber tyred wheels skidded on the wet metals, with the result that the car was swung completely round and fell into a ditch at the side of the road. Mr. Higgins sustained a fractured leg, and was taken to a local doctor, whilst the ladies were badly shaken and bruised.

IN reference to the report of a recent mishap near Maidstone, Messrs. Hulbert, Crowe, and Hulbert, solicitors, acting for the gentleman who was driving the motor-car write:—"The car was not being driven at a rapid rate, but, on the contrary, was at a standstill at the moment of the accident. The nurse who was driving the governess car had partly passed the motor-car when the pony got out of control, turned suddenly round, and when in the act of bolting put one of his hind legs through the spokes of the off-side front wheel of the automobile and fell. In struggling to get free the animal wrenched off its hoof, and had to be killed. The governess car was not touched by the motor, and was not damaged, and our client was in no way to blame for the occurrence."

Alas! Another Case against a Motorist Lost.

LETTERS OF IDENTIFICATION.

BELOW we give the identification marks for Scotland as required by the Motor Car Act:—

PETROL AND LUBRICATING OIL DEPOTS ON AND ABOUT THE 1904 GORDON BENNETT COURSE.

As mentioned in a recent issue, the Vereinigte Benzinfabriken, of Bremen, has issued a list of depots on and about the Gordon Bennett Course in Germany, where a stock of their Stellin motor-spirit, or benzin, as it is called in Germany, will be found available at the cost of 40 pfennings per litre (can not included), As the list may prove useful to many of our readers we reprint it herewith.

Homburg v. d. Hohe:

Menges & Mulder, Waisenhausplatz.
Carl Mathay, 11, Louisenstrasse.
Otto Voltz, 19, Louisenstrasse.
Georg Schick Sohn, Am Bahnhof, garage for 32 cars.
Carl Deisel, 44, Louisenstrasse.
Carl Kreh, Chemist, Louisenstrasse.
Wilhelm Kranz, Dorotheenstrasse, garage for 50 cars.
Clemens Wehrheim, cycle depot, Louisenstrasse.
Hotel Adler, garage for 22 cars.
Hotel Bellevue, garage for 10 cars.
Hotel Windsor, garage for 4 cars.
Sauer & Hillebrandt, 76, Louisenstrasse, garage for 50 cars.
Actien Brewery, Höhenstrasse, garage for 100 cars.
Jean Becker, Louisenstrasse, garage for 11 cars.
Chr. Acker, Castillostrasse, garage for 50 cars.
Albert Schick, Neuer Weg, garage for 30 cars.
Chr. Lanz, Dorotheenstrasse, garage for 50 cars.
Hugo Eppstein, Elisabethenstrasse, garage for 12 cars.
F. Strauss, 22, Kaiser Friedrich Promenade, garage for 4 cars.
F. Idstein, Kaiser Friedrich Promenade, garage for 7 cars.
Adolf Merle, Ferdinandsgarten, garage for 3 cars.
Franz Supp, Louisenstrasse, garage for 3 cars.
W. Zimmerschied, Deutsches Haus, Dornholzhauser Chaussée.

Dornholzhausen:

Hotel Scheller, garage for 20 cars.
Gärtnerei Maas, garage for 10 cars.

Saalburg:

Saalburg Restauration.
Hotel Cruciger.

Wehrheim:

F. A. Velte.

Heinrich Kornacher.

Konigstein:

W. Zehe 27, Hauptstrasse.
Hotel Colosseus, Hauptstrasse.

Gronberg:

H. Gerstner, chemist.
Hotel Frankfurter Hof.

Ober-Ursel:

Alex Kürtell, 4, Oberhochstadterstrasse.
Jos. Abt.

Friedberg i. Hessen:

J. Baumeister, Hauptstrasse.
W. Flaschenträger, Hauptstrasse.
Albert Gennes, chemist.

Bad Nauheim:

Richard Schwab.
B. Peters, chemist.

Frankfurt am Main:

August Ulrich, 1, Friedenstrasse, garage for 60 cars.
Kaiseröl-Fabrik-Niederlage der Petroleum-Raffinerie vorm. August Korff.
Dr. A. Jassoy, 63, Neue Zeil.
Seiffermann & Uhl, 7, Kronprinzenstrasse, garage for 200 cars.
Hoelzle & Chelius, 4, Catharinenpforte.
Carl May, 51, Kronprinzenstrasse, garage for 20 cars.
Adler-Fahrradwerke Garage, The, Gutleutstrasse.
Joh. Häusler, 10, Opernplatz.

Wiesbaden:

Hotel und Restaurant Grüner Wald, 10, Marktstrasse, garage for 10 cars.
Otto Sassmann, 21, Westerdstrasse, garage for 6 cars.
Carl Kreidel, 36, Webergasse.
Hugo Grün, 3, Kirchgasse.
Friedr. Becker, 2, Moritzstrasse.

CASES DISMISSED.

THERE was an adjourned summons before Mr. Lane, K.C., at the West London Police-court on Tuesday, against the Garage Company (Limited), of Queen-street, Cheapside, E.C., for infringing section two of the Motor Car Act, 1903, by "fraudulently allowing an unregistered motor-car to be used" in the Hammersmith Road on March 5. Mr. Wontner appeared to support the summons on behalf of the Commissioner of Police, and Mr. H.W. Nicholson represented the defendant company. On the day in question a motor-car numbered "A.I.G.H.," and driven by Mr. C. V. Moore, was stopped in the road by Police-constable 789 T, who noticed that the letters were not properly fixed. Inquiry showed that though the car was the property of Mr. George Edwardes it bore the identification mark of the defendant company, to whose garage it had been sent for repairs, and it was not registered. Mr. Moore, who was subsequently summoned for "using an unregistered car," pleaded that the company lent him their identification mark for the purpose of his trying the car to see if the repairs were sound, Mr. Edwardes, who was a friend of his, having asked him to do so. The magistrate, however, held that he had clearly infringed the Act, inasmuch as the car not being the property of the Garage Company, nor "on trial by an intending purchaser," did not come within the exemption granted under sub-section 4 of section 2 to cars of that description, and he accordingly imposed on Mr. Moore a penalty of £3. On the present summons the point at issue was whether the company had acted "fraudulently" in so lending their identification mark. Mr. Nicholson argued that the company had acted in perfect good faith. The car was given to them to repair, and while under their charge was lent to Mr. Moore for the purpose of testing the repairs, after which it would return to the garage. He further pointed out that the reason the car was not registered was because it was sent to the garage before the Act came into operation. The magistrate said the word "fraudulent" used in that particular section of the Act clearly applied to a case where a man did something which enabled another person to represent that he was the owner of the car under the title of these "marks," or that he was the intending purchaser of the car. In this case he was satisfied that whoever allowed the company's marks to be attached to the car believed—and it was not a very violent presumption on the part of a layman—that a car taken out on trial for the purpose of testing the repairs was in the same category as one being tested by an "intending purchaser," or a new car being tested for its running qualities "after completion" by the manufacturer. It should, however, be clearly understood by owners and manufacturers of motor-cars that the words "intending purchaser" meant exactly what they said, and could not be extended to cases of cars on repair. He was satisfied that there was no "fraudulent permitting," and he therefore dismissed the summons.

AT Godalming, Ernest Moore, motor-car driver, High Barn, Hascombe, was summoned for driving his motor-car in Town End Street at such a speed as to be dangerous to the public, on the 11th March. Mr. L. de Michele, instructed by Mr. F. Dowse (Messrs. Mellersh), appeared for the defendant, who pleaded not guilty. Alfred Chaplin, a motor-car driver, who was with the defendant on the day in question, corroborated the evidence of several witnesses. Mr. Stuart Pleydell-Bouverie, living at High Barn, Hascombe, said he was a director of the Wolseley Company, Birmingham. Defendant was sent to him by the company as an experienced driver, and one of the best they had got. He had absolute confidence in him. Chaplin was learning under Moore's tuition. He impressed upon both of them to be most careful in driving, with every consideration for the public. The magistrates decided that there was not sufficient evidence that the defendant was going at an excessive rate of speed, and dismissed the case.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, APRIL 23, 1904. [No. 268.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ON the 1st prox. the Irish Automobile Club will enter into the possession of new premises, which have been secured in Dublin, and which will give the organisation a prestige and influence it has not hitherto enjoyed. During the coming summer several good runs will be made to Enniskerry, Killaloo, Malahide, Lucan, and other places near and far from Dublin. The runs will start from the Shelbourne Hotel, Dublin, early in the afternoon. During July, the annual tour of about nine days' duration will be held. It will include a reliability trial at Killarney, and some enjoyable trips in the beautiful Glengariff country, as well as runs as far as Lismore and other delightful spots which were included in the itinerary of the tour following the Gordon Bennett race of last year. Evidently the Irish motorists intend to have a busy as well as a pleasant time together during the coming season.

◆ ◆ ◆

Motor-'Buses for London.

WE understand that the officials at Scotland Yard have made an inspection of one of the motor-omnibuses now in use at Eastbourne, and have expressed themselves in favour of licensing vehicles of the same type for service in London. A 'bus has been run from Peckham to Charing Cross and back with some prominent officers of the Metropolitan police force as passengers and within a short time some of the familiar horse-drawn vehicles now in use may be withdrawn by a certain popular 'bus-owning firm in favour of the more modern vehicles. Frankly it must be confessed the London public have so often heard rumours as to the establishment of motor-'bus services that their present scepticism may be excused. But come it must, and the sooner the motor-'bus is a familiar feature of the streets the better will it be for the public convenience.

◆ ◆ ◆

Up Porlock Hill.

THE first motor-car to ascend Porlock Hill, near Minehead, was a Napier, which accomplished the feat in August, 1900; later in the same year a Benz made the ascent, since when little has been heard of sensational rides up the steep and famous hill. On the 6th of the present month, however, Mr. J. T. Overton made the ascent on a 16-h.p. Georges Richard car, which was then driven over to Lynmouth and into Lynton. On the following day Mr. Leonard Spong, who had been appointed Hon. Observer by the A.C.G.B I, arrived, but it had rained during the night and the hill was in a very bad condition. A set of Parsons non-skid chains were, however, fitted, and with four persons up the test was tried again. Starting at 10 a.m., Porlock Hill, with four persons up, was negotiated with the utmost ease. From the Ship Inn to the sign-post at the top of the hill, a distance of over three miles, was covered in eighteen minutes, making an average of ten miles an hour. Lynmouth was reached in forty-one minutes, a distance of 11½ miles, including several stops made on the way for restive horses. The hill up from Lynton to Lynmouth was then attempted, but, owing to the very wet condition, it was not very successful; on a second attempt the car was driven up with one person without a stop or any assistance. A return journey from Lynmouth to Porlock was done at an average up to the legal limit. Ilfracombe to Minehead is, according to the Contour Road-book, the worst main road in the South of England. The road then runs to Lynmouth by a sheer descent with an awkward twist at the bottom—about the most dangerous hill in the country. Porlock is then reached by another sheer descent with two twists near the bottom; there is scarcely any surface to this part of the road. The gradients are given as:—Lynmouth 1 in 5 and the other side 1 in 7 for over two miles, Porlock 1 in 10, 1 in 8, and 1 in 6.

◆ ◆ ◆

Club for Dorset.

AWAY in the West of England motoring is becoming as popular as elsewhere, and the organisation of motorists is proceeding rapidly. At the April meeting of the Gloucestershire Club, reported on another page, great progress was recounted, and, during the last few days, a meeting has been held at Dorchester for the formation of an automobile club for Dorsetshire. At the latter the Hon. Wilfred Cairns presided, and among those who have already given their names as members are Lord Ilchester and Lord Wimborne. We welcome the growth of such associations, their work not only being to encourage automobilism, but also to protect motorists from petty police persecutions.

◆ ◆ ◆

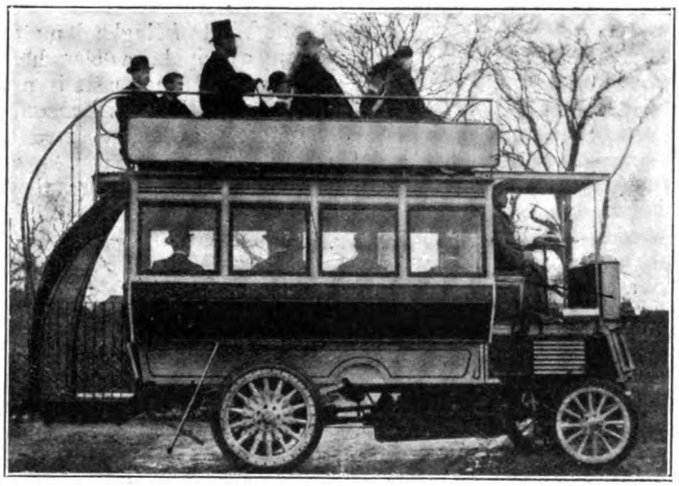
Traders and Private Marks.

GRADUALLY the peculiarities of the new motor-car legislation are being made plain, and a case at Leeds presents an answer to the conundrum "When is a registered motor-car not registered?" A private car bearing a manufacturer's identification mark was being driven under conditions which applied only to new vehicles for trial after completion or cars on trial by intending purchasers. Therefore, it was successfully contended by the police, it was unregistered and the driver liable to a heavy penalty. The case should prove a useful warning to others.

◆ ◆ ◆

In the West.

AT the last meeting of the Taunton Town Council the Town Clerk read a letter from Dr. A. Kepple-Reade, the chairman of the Parish Council of Churchstanton, enclosing a resolution passed by that council in favour of petitioning the G.W.R. Company and the L. and S.W.R. Company for the establishment of a motor-car service between Taunton and Honiton, and asking for the support of the Taunton Town Council with regard to the same. Mr. Kirkpatrick thought that if they could get the G.W.R. Company to grant this motor-car service, it would be a splendid thing for Taunton in more ways than one. For one thing, it would give the inhabitants of Taunton a better opportunity of getting to the South Coast, and it would also tap Honiton and probably bring to Taunton a large amount of trade which now went to Exeter. He proposed that they should support the petition. Mr. Sibley seconded the motion, which received unanimous support on the



Digitized by Google

ground that the service would bring a great deal of business to the town. The motion was carried, and was then referred to the General Purposes Committee, with a request that they would take joint action with the Honiton Council as soon as possible.

◆ ◆ ◆

Motor-Omnibuses for the Colonies.

FOLLOWING two Stirling single-deck omnibuses which have been in use in Western Australia for about nine months, the Stirling Motor Construction Company, of Edinburgh, have just shipped a consignment of double-decked omnibuses to Fremantle. These vehicles have been specially designed for use in Perth, Western Australia, and have many interesting features. Accommodation is provided for 30 persons, 14 inside and 16 outside. The motor is of 24-h.p., and the speeds 4, 8, and 12 miles an hour. On large vehicles of this description, on which the public demand rubber tyres, it is of the greatest importance that while great strength in construction is required, they must not be unduly heavy, otherwise the maintenance of the rubber tyres becomes excessive. In this respect Messrs. Stirling are to be congratulated on producing a thirty-seated vehicle weighing not more than 2 tons 15 cwts., or about 20 cwts. less than most vehicles of this capacity. Another point of importance in omnibuses for town work is their over-all length in relation to their carrying accommodation.

In the Stirling 'bus illustrated herewith this is kept within reasonable limits owing to the compact form in which the box seat is placed over the motor, thus saving about five feet in the length compared with designs having the motor under a bonnet in the usual way. The extreme width is 7 feet, and the upper deck is reached by an easy stairway. The well-known "Stirling" system of transmission is used in these omnibuses, and also their system of natural circulation of the cooling water. The vehicles are fitted with powerful brakes, while two ignitions are provided to the engines—high tension from accumulators and low tension magneto.

◆ ◆ ◆

Post Office Service.

A PARAGRAPH has been going around the press stating that the Post Office would be willing to contract with motor-van builders to supply a number of vehicles for use in the service were such automobiles of a reliable and steady running character. This is news which has been before the trade for the last few years, and we begin to think that the dilatory methods of the postal authorities are partly responsible for the delay of that Government department in adopting a means of locomotion which has proved applicable in other countries. As a matter of fact, a motor-van is being used for the mail service between Epping and London, and we believe this car has run continuously for the last six or seven months, only being late on one occasion. This was owing to causes which have no relation whatever to the vehicle. Mails are now carried between Liverpool and Manchester by motor-cars, and an extension of the system should be made ere the British Post Office is left behind the Continent in this matter.

◆ ◆ ◆

Cricketers and Motoring.

MR. C. B. FRY, cricketer, footballer, writer, and a dozen other things besides, may frequently be seen on his motor-car, and now we hear of another well-known cricketer joining the ranks of motorists in a practical fashion. Mr. L. C. H. Palairet, the England and Somerset cricketer, has joined the Bridgwater Motor Company, Limited, and will actively interest himself in the automobile industry. The advent of sportsmen like Mr. Palairet into the business will ensure its continuance with energy and enterprise.

◆ ◆ ◆

The Indecision of Pedestrians.

THE first fatal accident im Liverpool in which a motor-car was involved has just taken place. Such fatalities are always regrettable and generally unavoidable. In this case the result would probably have been identical had the vehicle been drawn by a horse instead of being propelled by a motor. An old lady was crossing the road when she saw a motor-brougham being driven by the driver to the City Engineer coming along. She halted in the roadway as he was slowing down. Naturally when he saw her stop he determined to go on, and so quickened his pace. The lady at that moment seems to have decided to continue crossing the road and stepped in front of the car, by which she was knocked down. A fatal result followed the accident, and at the inquest the jury returned a verdict of "Accidental death," exonerating the driver from all blame. Mr. J. A. Brodie, the City Engineer, who was riding in the motor-car at the time, confirmed other witnesses as to the occurrence and testified as to the care of the driver. But the accident enforces an opinion we have often expressed as to the indecisiveness of pedestrians when crossing the roadway being responsible for many of the mishaps that occur in the streets.

◆ ◆ ◆

The late Sir Henry Thompson.

THE death of Sir Henry Thompson robs London Society of its most eminent surgeon and the automobile movement of one of its most important advocates. Sir Henry's distinguished medical career and his success as an artist have been the themes of the newspaper obituary notices. We would, however, add a word as to his enthusiasm for motoring. In June, 1901, he bought a 6½ h.p. car and forthwith began a two months' tour in Buckinghamshire and Berkshire, making Boxmoor his headquarters. Although he engaged a driver, he was at some pains to become fully acquainted with what he called the "Anatomy and Physiology" of the car. In August of that year he wrote to the "Times" and inaugurated an important correspondence on the attitude of drivers of horses to automobiles, which proved the most useful to the motoring fraternity of any series of letters appearing outside the columns of the motor-car press.

◆ ◆ ◆

Police and Speed.

SIR HENRY was a regular reader of the *Motor-Car Journal*, and in his book on the subject referred to the records we published some time ago as to the heavy fines obtained from victims of police traps. Before Parliament fixed the speed limit at twenty miles an hour, he declared that "the pace of a motor-car on an open country road may certainly be safely permitted to reach twenty miles an hour and cannot be regarded as 'furious.' It seems now to be quite forgotten that steam-coaches were driven with perfect safety at fully this speed on good and open roads in the former half of the last century." Only within the last few weeks had Sir Henry Thompson enjoyed some long motor-car rides, and he will be much missed in a wide section of London society.

Digitized by Google

The Motor-Car on the Racecourse.

Of the utilities of the motor-car there is no end, and even on the racecourse it has shown its value. On Tuesday Mr. G. T. Langridge, a motorist resident at Epsom, was at the races when an unfortunate incident occurred on the course. In the race for the Great Metropolitan Stakes there was a regular scrimmage, as St. Patrick's Day struck into either the favourite or Puerto, and came down, Grey Tick and Induction falling over him. It was at first feared that the jockeys had been badly hurt, and Mr. Langridge's car was at once requisitioned to take two of the unfortunate riders to the hospital, where it was discovered that their injuries were not so serious as had been supposed.

◆ ◆ ◆

"Chauffeur Petrol."

According to a Canadian contemporary, the proceedings at the first annual banquet of the Toronto Automobile Club were enlivened by several "genuine letters of regret," including a code cablegram "by command of His Majesty King Edward from Henry Petrol Hankins, chauffeur in extraordinary to the royal garage." This is said to have "brought down the house," a catastrophe not to be unexpected. Something serious once happened to Ananias, but it only happened once.

◆ ◆ ◆

Quashing Convictions.

During the progress of the Motor-Car Bill into an Act we expressed a hope that every opportunity for appeal would be taken advantage of, so that police and magistrates would be taught to recognise that care should be paid to accurary, even when dealing with such maligned persons as motorists. So far, two appeals have been made and both have been successful in quashing the original convictions. Last week we recorded an instance at Beaconsfield, now we are able to congratulate Mr. J. R. Egerton, of Ipswich, who appealed to the Quarter Sessions against a conviction by the Ipswich magistrates on a charge of driving a motor-car in a manner dangerous to the public. The constable, questioned by the Recorder, showed great carelessness in distinguishing between "a man" and "people"; while under cross-examination by Mr. Wild, his views as to speed were found to be somewhat visionary. In addressing the Court for the appellant, counsel contended that under the conviction there must be real danger to a person or persons proved to be actually using the highway at the time, because certain words of the section had been omitted from the charge. The danger must be actual, and not hypothetical. He submitted as a matter of law that there was no evidence of actual danger. In the end the Recorder expressed himself as satisfied that Mr. Egerton was a careful and skilful driver and quashed the conviction.

◆ ◆ ◆

No Scales with Motor-Cars.

Section 9 of the Bread Act of 1822, under which a well-known firm have just escaped penalty at Brentford, applies only to "cart or other carriage drawn by horse, mule, or ass." Vehicles thus propelled have to carry scales, but the chairman of the Bench rightly observed that as nothing was said in the Act about motor-propelled carts he could do nothing but dismiss the summons, which he did accordingly. We do not advance this immunity from carrying scales as an argument in favour of the automobile, but it is significant of the way things are done by the Legislature that no effort has been made to bring the Bread Act up to date.

◆ ◆ ◆

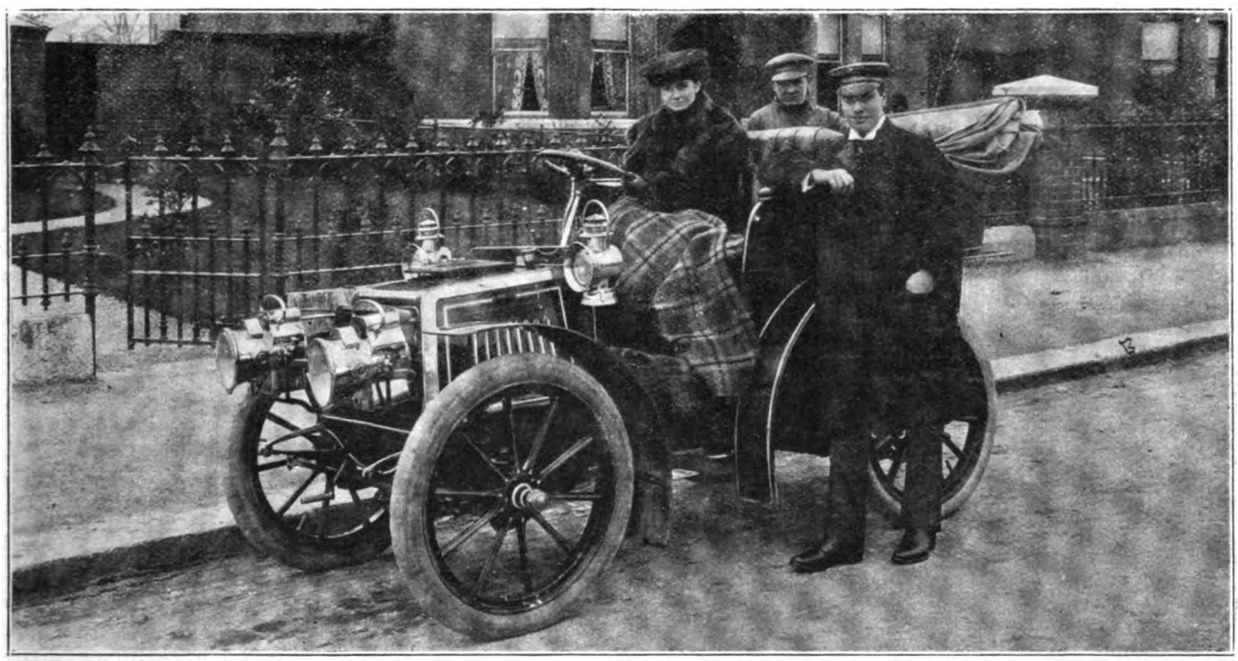


Photo by] Sir Valentine and Lady Grace and their Panhard Car. *[F. P. D'Arcy.*

An Indignity to the Press.

On Saturday the cars entered for the Eliminating Contest in the Isle of Man were weighed-in at the dimly-lighted and inconveniently arranged garage—we beg pardon, motor house — of the A.C.G.B.I. Representatives of the automobile press attended at an early hour to see the vehicles and record their impressions. But, alas for confiding journalistic nature! At the stroke of noon the order to clear the place of all save judges and drivers was given, and the Pressmen were ushered to the gates, which were closed behind them. Outside they were able to realise the ridiculously awkward means of exit and entrance to the establishment, which can only be regarded as a miserable makeshift for such a wealthy body as the Automobile Club.

◆ ◆ ◆

Courtesy in the Old Days.

But on the question of the treatment meted out to the Press something more should be said. In the old days of Whitehall Court the Press was regarded as worth consideration. In return, it helped to make the club what it is today. Now, however, times have changed. From its com-

Digitized by Google

manding position in Piccadilly it assumes an air of lofty indifference to those who have assisted to lay its foundations, and is, apparently, determined that now it has become a newspaper proprietor, no civility shall be shown to journalistic confreres. Such, however, is not in accord with professional etiquette, and would certainly not be tolerated even in parochial journalism. We doubt whether the proprietors of the "Eatanswill Gazette" would have thus acted towards other journalists in that locality.

◆ ◆ ◆

Repair of Roads.

THIS is one of the many seasons in the year when some of the local authorities seem to delight in renewing the surface of the roads. Where this is expeditiously done, no complaint can possibly be made; but, unfortunately, many of those responsible for the work are prone to leave the roads overnight in a very rough condition. Often, too, it is late before the steam roller can pass over these portions on the next day, with the result that motorists going that way have to run considerable risk of punctures. The point may not be apparent to local surveyors who do not care anything for motorists or other users of their roads, but it is an important one in view of the opening of the touring season, which, after the weather of the last few days, seems to be with us at last.

◆ ◆ ◆

Action by a Club.

THE subject has been before the Gloucestershire Club for discussion, and a resolution calling the attention of the Highways Committee of the County Council to the subject has been unanimously adopted. This set forth the unsatisfactory way in which the roads are left, more particularly from Saturdays to Mondays—just the period when outdoor pastimes are most generally indulged in. The remedy, of course, is to have all metal placed on the highway rolled in before work ceases for the day—a plan that might easily be adopted if the repair of the roads were properly organised and efficiently supervised.

◆ ◆ ◆

Sense in Wales.

WE are glad to see that practically the whole of the local authorities in Wales have recognised the Local Government Board's view with regard to the speed limit, and have refrained from unnecessary applications for its restriction. Newport, however, has obtained an unenviable notoriety by reason of the persistent way in which the town councillors have maintained their resolution to apply for a reduction of the speed limit to ten miles an hour. The Monmouthshire County Council, on the other hand, declined to make any such application, with the result that motorists in the county area may attain a speed of nineteen miles without being penalized, while one of eleven miles will be sufficient, should the Newport wiseacres have their way, to secure conviction. It is to be hoped that when the Local Government Board give their decision with regard to the Newport application, as well as to those of Winchester and Dover, something like uniformity in a speed limit of twenty miles will be obtained.

◆ ◆ ◆

Police Traps.

THE police seem to be renewing their trap-laying propensities, and from several parts of the country news comes of victims having been caught. The example of the Surrey police seems to have got as far north as Yorkshire, and motorists passing through Leeds are warned by the Yorkshire Club of the police trap at Roundhay Park. Constables are located near the police station, and also at the old entrance to the Park, and on Sunday last they were noticed busily taking numbers of cars passing that way, and also the time they occupied on the journey. If this sort of thing continues, we are afraid our northern friends will become as embittered against the authorities as a good many southern motorists have just cause to be. In consequence of the severe exposure of the police in Captain Morgan's case we understand they discontinued their underhanded methods for a while, but it has just come to our knowledge that they intend forthwith to commence their trap again. All Metropolitan motorists should therefore be exceedingly careful when proceeding along the Addison Road. The recent traps have been laid on the east side of the railway bridge near Addison Road Station. Any motorists stopped by these men should at once demand all particulars of the alleged offence and should examine both the stop-watches and take a note of the same at the time.

◆ ◆ ◆

A Record Australian Trip.

AUSTRALIA has already its automobile records, that for distance being held by Messrs. W. B. Wilkinson and W. A. Whitehead, of Stawell, Victoria. They have spent twelve days on a 6-h.p. car, touring *via* Melbourne, Wangaratta, Albury, to Sydney, returning to Stawell by much the same route. In reading an account of the run we were struck by the frequency with which the vehicle was stopped to allow horses to be led past—a reminder of the early days of the movement in this country. In most cases the fears of the animals were easily allayed. Several exciting incidents were, of course, met with; but even in the out-of-the-way places of the Antipodes the motor-car is ceasing to be an object of wonderment.

◆ ◆ ◆

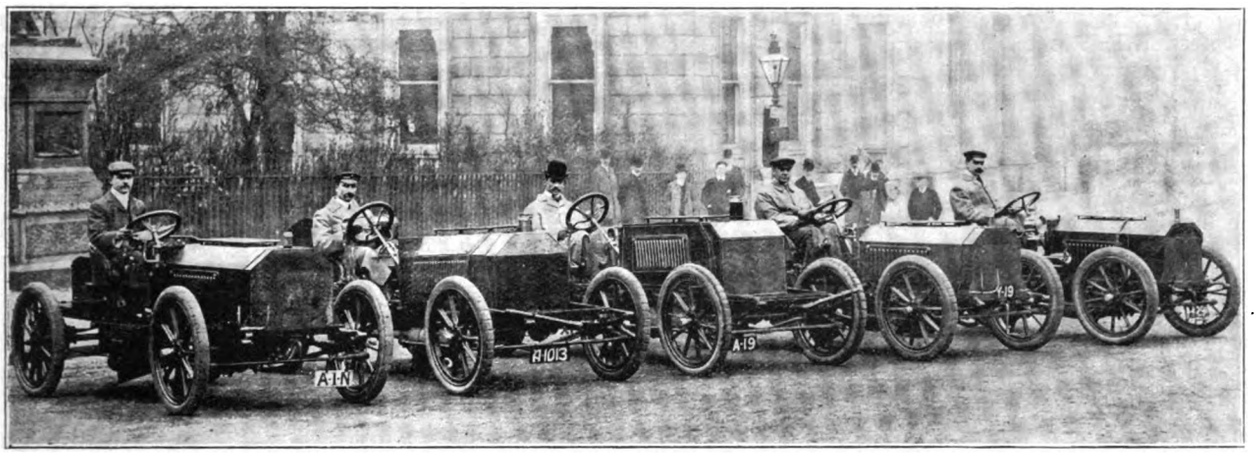
Progress at Bombay.

HARDLY a week passes that does not bring with it news of automobile developments in India, and now we learn of the formation of the Bombay Motor-Car Company to give attention to the movement in that important city. The Indian Government might further encourage the introduction of motor traffic by amending the inconsistencies in the Customs regulation dealing with motor-cars. A steam traction engine is imported into India free of duty, but a steam motor-car has to pay 5 per cent. duty. The Government endeavours to explain this anomaly by ruling that motor-cars carrying goods are free, but motor-cars carrying passengers are dutiable. Such a contention seems unreasonable as well as inconsistent, and an interesting instance has arisen in Bombay itself. The Bombay Municipality have recently imported a motor-car or wagon to transport mutton from Bandora to Bombay. It was imported free of duty, yet the same vehicle carrying passengers would cost its owner 5 per cent. more. An early occasion should be found to alter such an inconsistent ruling.

MR. E. MACRORY, K.C., who died on Monday, was one of the founder members of the A.C.G.B.I.

MR. J. LYONS SAMPSON was in charge of the weighbridge at the weighing-in of the British racers last Saturday.

ON Wednesday next the annual meeting of the Roads Improvement Association will be held at the Westminster Palace Hotel, London.



THE Official Information Department of the Manx Government, 2, Coronation Chambers, Douglas, will be pleased to supply information to intending visitors to the Isle of Man.

THE Louis Leaky Aluminium Company, Limited, are newcomers in the automobile trade. They are introducing a new 15-h.p. car known as the "Phœbus." It is fitted with a Mutel four-cylinder engine, and is on modern lines throughout.

ON account of so many members of the Nottinghamshire club intimating their intention of being present at the Eliminating Trials in the Isle of Man, the date of the next hill-climb of that club has been altered from the 14th to 28th May.

GORDON BENNETT RACE NOTES.

ON Saturday eleven cars of British make were weighed-in at the Automobile Club's garage and definitely accepted as fully qualified entries for the Eliminating Test in the Isle of Man. The judges for the purpose of inspection who were in attendance were :—Major Lloyd, Mr. Worby Beaumont, Colonel Crompton, Mr. Lyons Sampson, Captain Nugent, Mr. Mervyn O'Gorman, Mr. E. H. Cozens-Hardy, Mr. Claude Johnson, and Captain Bowman-Manifold. The work of inspection proved a long and tedious process, and lasted practically from noon till 6 p.m., only a few motorists being present to watch the departure of the vehicles.

◆ ◆ ◆

THE Wolseley cars—two with strange beetle-like bodies—were the first to arrive, turning into the garage shortly after seven o'clock in the morning. Then came the five Napiers, and as the minutes passed 11 a.m. it was wondered whether the Darracqs would arrive in time. Mr. J. Ernest Hutton was present, but no cars belonging to his firm appeared, and he had given up all hope of having them finished for inspection. Excitement grew as the hour of noon approached, and it was a visible relief when the three Darracqs appeared in Down Street ten minutes before the latest time for entering the garage.

Photo by] One of the British Darracq Racers entering the A.C.G.B.I. Motor House. *[Argent Archo*

THEN the Press were directed outside the building and as to what happened no record can be given. This was not the desire of the manufacturers who were within, for, as one of them told us, several of the mechanics could have been dispensed with to make room—if the absence of such was the excuse of the Club—for the half-dozen gentlemen who were present on behalf of the automobile journals.

◆ ◆ ◆

THE following are the weights of the several cars presented:—The five Napier cars weighed respectively 2,182, 2,111, 2,199, 2,177, and 2,144 lbs. The three Darracq cars, 2,205, 2,219, and 2,205 lbs. The three Wolseleys, 2,163, 2,157 and 2,191 lbs.

◆ ◆ ◆

THE Darracq cars left St. Enoch Station, Glasgow, by special train at 9.3 p.m. on Friday night, a great crowd cheering them on their way. Among those who assembled at the station were several members of the Scottish Automobile Club, including the Marquis of Ailsa, while the hon. secretary of the Western Section, Mr. R. J. Smith, accompanied the cars to London, where they arrived on Saturday morning. Chatting with Mr. William Weir, of the firm of G. and J. Weir, who had been responsible for the oversight of the cars during their construction in Scotland, we learned that the firm do not at present contemplate entering the automobile industry. They accepted the order to build three racing cars merely as an engineering feat, and are naturally proud that, never having made a car before, they should have been able to complete the three cars in time. Altogether 800 men must have had a hand in the work, and for some weeks over sixty have been continuously engaged on the cars—the Scottish idea of the Sabbath being thrown to the winds and the work done in three shifts of eight hours each.

◆ ◆ ◆

THE Darracq cars have motors capable of developing 90-h.p. at 1,500 revolutions, a speed which can be considerably accelerated. These are hung low in pressed steel frames. There is a direct drive to the rear live axle. In addition to the high tension ignition a magneto is fitted. In their grey square bonnets the cars looked formidable rivals, although the manner of their leaving the garage was less nimble than that of the Wolseley and Napier racers, which were driven away at the close of the afternoon. The Darracq cars have bolted Michelin tyres which have been made in London, no less than nine tons of machinery having been sent over by the French company so that the conditions of entry might be kept to the letter.

◆ ◆ ◆

AT Saturday's inspection, Mr. A. Rawlinson, who will drive one of the Darracq cars, was in charge of the contingent. The other drivers will be MM. Hemery and Edmond.

◆ ◆ ◆

MR. J. W. ORDE has again visited the Isle of Man to decide where the hill-climbing tests will be held. It was originally thought the hill-climbing tests would be made from Ramsey to Snaefell, but later advices suggest that the tests may be up Creg Willey's Hill (at Glen Helen), or Crellin's Hill (Douglas).

◆ ◆ ◆

COLONEL FREETH and Supt. Boyd are driving out daily on the route of the British eliminating race, engaging intelligent men to serve as special constables on the day of the trials. Five hundred men are required, and of these more than two hundred had been engaged at the beginning of the present week.

◆ ◆ ◆

A MEETING of the Douglas Committee appointed in connection with the coming races was held in the Town Hall last week. The Mayor presided, and there was a large attendance. A copy of a telegram from Mr. Orde, secretary to the Automobile Club, to His Excellency Lord Raglan was read, in which it was stated that the events for the 10th and 11th of May—the trial races and the hill-climbing contests—were fixed, but that the date for speed trials along the front of Douglas Bay was not as yet definitely settled.

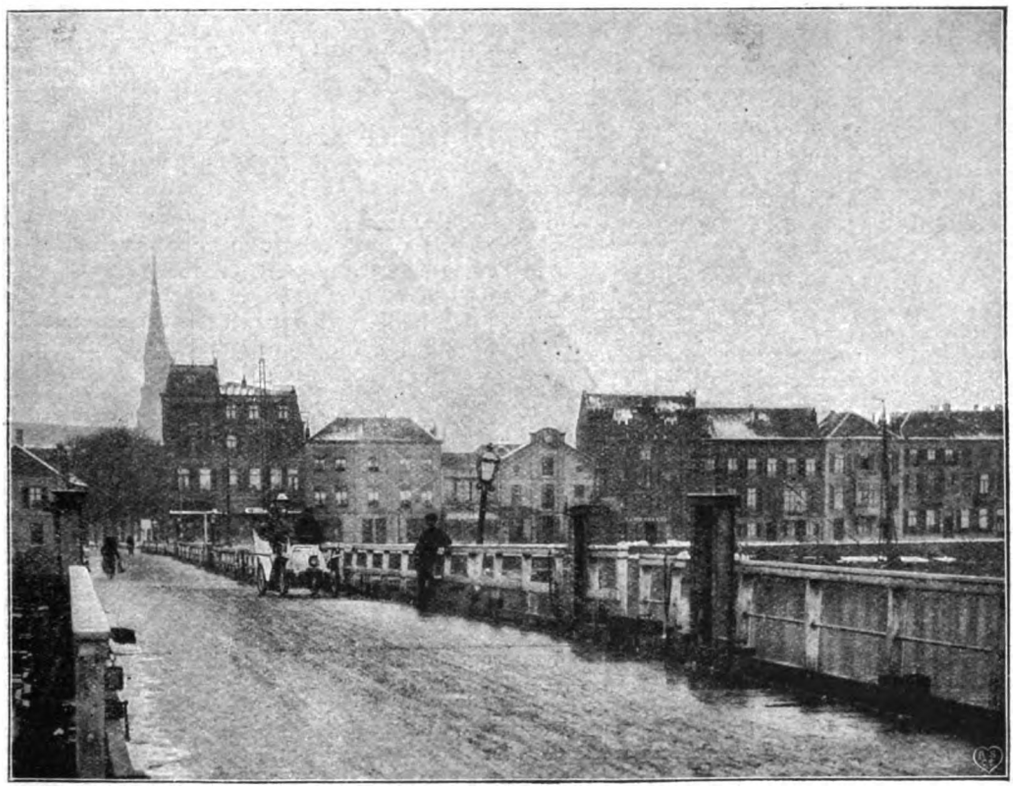
Digitized by Google

THE brief itinerary of the race is as follows:—Starting from the Quarter Bridge, about a mile outside Douglas, the cars will be driven through Ballasalla, 8 miles; Castletown, 1·4; Foxdale, 7·1; Kirk Michael, 8·7; Ballaugh, 2·1; Ramsey, 9·1; Willaston, 13; and Quarter Bridge, 1·4; a total distance of 51·1 miles, which in all probability will be covered six times, thus making a total of rather more than 300 miles—a far more adequate test than the mile runs indulged in on the Welbeck course last year.

◆ ◆ ◆

THE following are the names of the drivers of the various cars which will compete in the French eliminating contest on the 20th May:—

DE DIETRICH.—Jarrott, Gabriel, and Baron de Forest.
PANHARD.—H. Farman, Teste, and Tart.
BAYARD-CLEMENT (Talbot).—A. Clement, jun., Guders, and Hanriot.
DARRACQ.—Baras, Beconnais, and Wagner.
GEORGES RICHARD-BRASIER.—Thery, Caillois, and Stead.
MORS.—Sallerons, Leger, and Lavergne.



AN American correspondent writes that it is possible that the American elimination trials, if such trials are required, may not be held at Ormond Beach, Florida. The failure of Mr. Alden Sampson to have his car ready and the inability to secure information from Mr. P. Cooper Hewitt as to the present condition of his car, seems to indicate that only the Peerless cars will be ready for the A.C.A.'s inspection. If trials are deemed necessary an effort may be made to try the cars on some course nearer New York than the Florida beach. Altogether rather pessimistic rumours are current with regard to the American team for the Cup race. There are those who prophesy openly that there will be no trials at Ormond, and in fact, no American team at all in the great contest.

◆ ◆ ◆

THOSE motorists who intend to visit Germany for the Gordon Bennett race, and who have not yet made any arrangements in regard to accommodation, are advised to write to the "Wohnungs-Nachweis fur das Gordon Bennett Rennen, Kurhausbad, Homburg von der Hohe." The committee which has this department in hand announces that there are still about 4,000 rooms available at moderate prices, ranging from five shillings. Good rooms, not attics, are to be had at this charge, whilst accommodation can still be found for 1,000 cars.

◆ ◆ ◆

THE German Automobile Club announces that tickets for the two grand stands which are to be erected on either side of the starting and finishing point of the Cup race at the Saalburg will be sold at 50 shillings each. These stands have seating capacity for 3,000 persons altogether, and include numerous boxes with four or six seats. Two elevated platforms adjoining the stands are also in course of construction and will afford accommodation for several thousands of visitors. The seats here are not numbered, and are available to all who obtain a pass, for which the charge is 20 shillings. Another stand is to be built on the course between Homburg and the Saalburg, tickets of admission to which are obtainable at the moderate price of 5 shillings.

A Cudell Car on the Floating Bridge over the Rhine at Arnhem, Holland.

GOBRON-BRILLIE.—Rigolly, Duray, and A. Burton.
HOTCHKISS.—Baron P. de Crawhez, A. Fournier, and Amblard.
TURCAT-MERY.—Rougier and De la Touloubre.
GARDNER SERPOLLET.—Le Blon, Chanliaud, and Pelzer.

Some surprise has been expressed at the absence of the name of Henri Fournier in the Hotchkiss team. It is stated that this well-known motorist has decided to give up racing and to devote himself entirely to business in the future.

◆ ◆ ◆

THE first of the Hotchkiss Gordon Bennett racers is now on the road. The body of the car takes the form of a long torpedo, the wheel base of the vehicle being nearly ten feet. The four-cylinder engine is stated to develop 100-h.p. at a speed of 950 revolutions per minute.

◆ ◆ ◆

WE are informed by the London Motor Garage Company, Limited, the English agents of La Compagnie Belge de Construction d'Automobiles, that the drivers of the three "Pipe" cars running for Belgium in the Cup Race are M. L. Hautvast, M. G. Augieres, and Baron Pierre de Crawhez. Augieres, it will be remembered, was the holder of the world's record until recently, and Baron Pierre de Crawhez was the winner of the Circuit des Ardennes race last year.

THE NAPIER MOTOR-BOAT.

By S. F. Edge.

THE question of building a suitable motor-boat to defend the British International Cup and the Gaston Menier International Cup, both held at present by my Napier boat, is a very serious one, in view of the fact that so many countries are this year taking up the motor-boat most energetically, and are making a very serious bid to try and take these cups away from English manufacturers. I suppose that most people feel as I do, that even if we cannot be uniformly successful on land with our British motors, we must never lose our supremacy on the sea, and, with this fact before us, the question of the Napier defender has engaged our most serious attention for a great many months past; the result we hope to have on the water towards the latter end of next month.

The question of the engine, reverse gear, and all machinery appertaining to it, and the building of the same, have been engaging Messrs. Napier's attention at Acton for some considerable time, and the machinery is just about ready to put into the hull, which is being built by Messrs. Yarrow, the famous torpedo boat constructors. To give some idea of the time, energy, experiments, and money that must be expended before first-class results can be obtained, I have had a series of photographs taken which deal merely with the question of the shape of the hull. These have nothing to do with the hundred and one experiments that have been carried out with regard to the most suitable material for the hull, the system of building it, the best kind of engine to be employed, where the weights shall be placed, how many revolutions per minute the engines run best at, and the kind and number of propellers. Each and every one of these subjects is in itself an exhaustive matter, and when one thinks that only the shape of the hull is dealt with in these photographs, I need scarcely say more on this head.

The hull experiments were as follows. First to build a number of full sized models, giving an exact reproduction of last year's boat, with which we have had tangible results. Then to try this same boat at speeds in excess of what it did last year, as our new boat must be much faster. Now to carry out our tests, after having made the various models, we had to get a torpedo boat, shown in Fig. 1 with one of our models lying alongside. The boat in question is a very fast boat, built by Messrs. Yarrow, and fitted with their turbine engines. The photograph also rather clearly shows the boom used for towing, as, of course, it was necessary to tow the model some little distance from the side of the vessel, so as to be entirely free from wash, and that is also why it is towed up so close to the bow of the torpedo boat, so as not to feel the wash from the torpedo boat itself, and also at the same time to be in a position where most careful observation and records could be made, and photographs taken.

Photograph No. 2 shows a photograph of the model of the old Napier, travelling at twenty knots. In the third photograph is a view of the same boat at twenty-five knots, from which it will be seen that the disturbance of the water was very great, and that the model was quite unsuitable for a twenty-five knot speed. Photograph No. 4 shows a development in which we got a very perfect bow wave at twenty-five knots, but the stern wave was very bad and we had to give it up.

In the fifth photograph is a model which gave most excellent results so far as bow waves was concerned, and a clean run from the stern, but, unfortunately, whilst being very perfect in absolutely smooth water, as can be seen from the photograph, this in the end was found quite hopeless in rough water. It would not steer properly, and other defects became apparent. The same model is illustrated in the sixth picture. In the centre will be noticed the water indicator for showing whether the boat kept a level keel or not. In these experiments a great number of scientific details had to be thought out. No. 7 shows what we thought was a fine model, until we got her at speed, and then we found, although she took very little power to pull her (and all the pull is registered by a dynamometer, so that we knew exactly what each model took to move through the water), the bow waves, although being light water, still made it rather hopeless, as the boat would have been very difficult to steer, and exceedingly damp for the people steering.

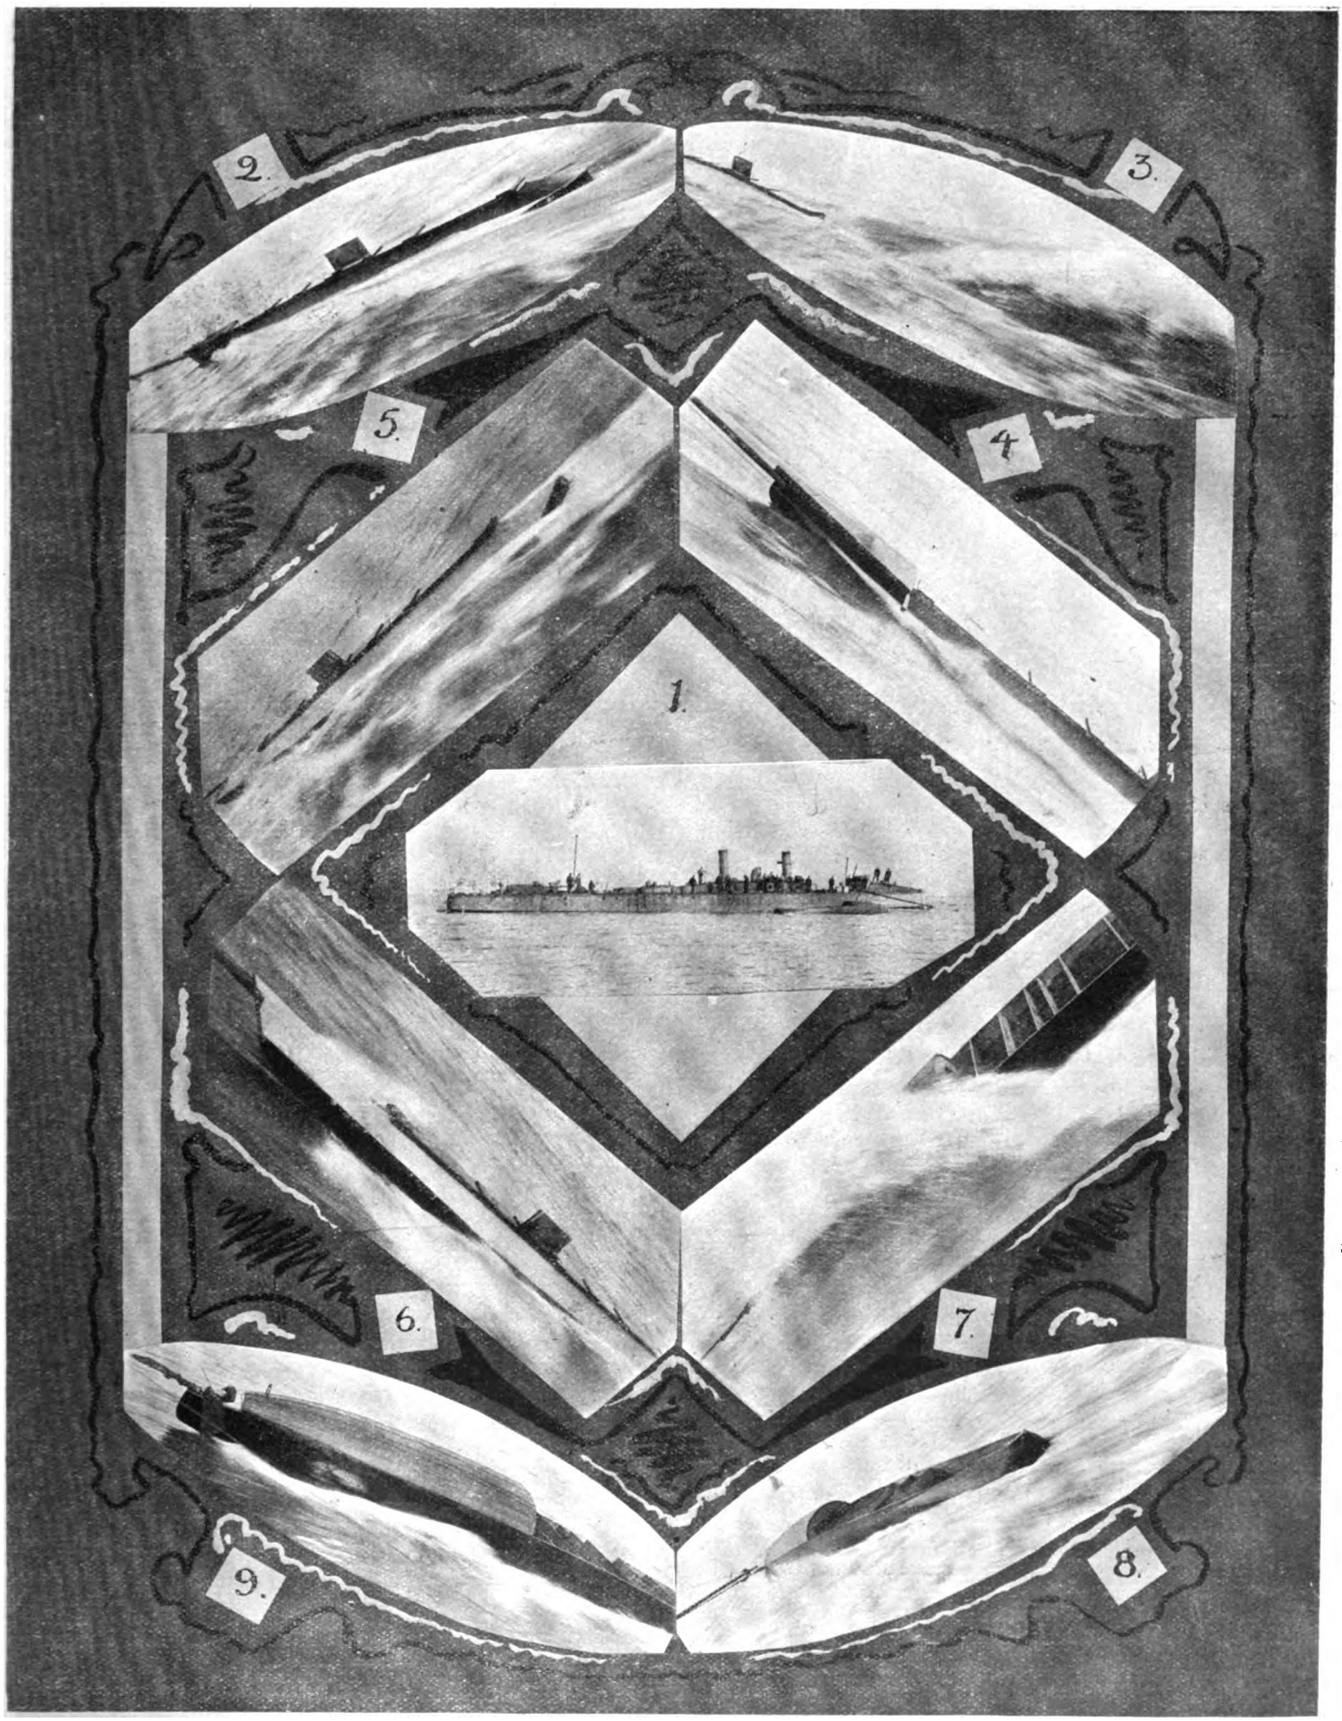
A fine model is that shown in Fig. 8, which clearly demonstrates the extraordinary clean run from the stern, and the relatively small bow wave. No. 9 shows even more clearly that the bow wave is almost non-existent at a speed of 25 knots, equal to 28·788 miles per hour. These photographs, as I have previously mentioned, merely indicate one direction in which our experiments had to be made.

Unfortunately we had bad luck with our cruising model at Monte Carlo, as, contrary to everyone else, we have determined to keep our motor-boats quite silent. Others have simply let their exhaust go straight into the air, and with 200-h.p. engines the noise may be more readily imagined than described. We had some difficulty in keeping our exhaust properly water cooled, because suitable pumps had never so far been manufactured, and here again we have had to experiment for ourselves, and invent pumps for the purpose. These will shortly be accomplished, and then we shall not have the same trouble as we had at Monte Carlo, which threw our 35 ft. cruiser out of the race.

PROGRESS IN CYLINDER DESIGN AND CONSTRUCTION.

IT is evident, from the care which manufacturers are giving to the fit of pistons in their cylinders, that the motors now being produced are likely to be highly satisfactory as regards ability to hold compression. Not only are cylinders being bored with greater exactness in point of perfect rotundity of section and equality of diameter at all points, but a great deal of attention is expended upon the manufacture of the piston rings, to cause them to fit the sides of the piston grooves, and upon the peripheral surface which bears upon the cylinder walls. No matter how perfectly the rings are fitted, however, there is inevitably a break in each one which allows of its expansion to conform to the contour of the cylinder wall and to compensate for wear, and no practical method has ever been devised to prevent the escape of gas at this point. Until of late the number of rings employed upon the pistons of automobile engines has been three, but recently quite a number of manufacturers have begun to employ a larger number, four rings are common, and in some instances five are made use of. This increase in the number of rings employed must tend to minimize to a very high degree the escape of the charge.

Another direction in which progress is to be noted is, remarks the "Horseless Age," in the designing of cylinders so as to be proof against loss of true cylindricity through unequal expansion. It is held in some quarters that the cast water jacket with its cored passages and widely varying wall section acts to encourage cylinder deformation when the motor is hot, and the sheet metal jacket, with its flexibility, is claimed as a solution of the difficulty. Whatever the merits of the case may be, it is clear that the attention of designers is attracted more than hitherto by the problems arising from the change of cylinder-contour due to heat and the effects thus produced upon compression and engine friction.



Baron de Caters is credited with the intention of making an early attempt to lower Rigolly's kilometre record. He will make the trials on a 90-h.p. Mercedes on the new Ostend road.

Messrs. Tilling, Limited, obtained damages in the Wandsworth County Court against Mr. C. F. Newman, a contractor, of Pope's Grove, Strawberry Hill, for causing injury to two of their omnibus horses with a motor-car. The defence was that the omnibus was suddenly pulled up and so caused the accident. Judge Russell, in finding for the plaintiff company, said that if people in charge of motor-cars could not control their machines in time of emergency they must take the consequences.

CONTINENTAL NOTES.

The King of Italy Welcomes the Motorists.

Italian motorists are jubilant over the reception they have received at the hands of the King of Italy, himself an enthusiastic automobilist. His Majesty recently accepted the invitation of the Club to become its honorary president, and in celebration of this it was decided to offer him an illuminated diploma of office. Accordingly a "caravan" of motorists set out early last week from Milan to convey the parchment to Rome. To their surprise they were met on the outskirts of the capital not only by all the leading motorists in Rome, but by the King himself, who, after inspecting the various cars, headed a procession to the Quirinal.

◆ ◆ ◆

Touring on the Continent.—A group of De Dion Cars at the Cathedral at Rheims, and at Rocroi.

◆ ◆ ◆

Improving Hotels.

The Italian Touring Club, which has been devoting attention for a long time past to the question of improving the hygienic conditions of hotels, has just issued an interesting booklet on the subject. It deals with the questions of heating, ventilation, illumination, etc., and gives many hints which should be of considerable use to Italian hotel proprietors. The C.T.I. has also issued a very useful map of the district forming the Swiss-Italian frontier.

◆ ◆ ◆

The Paris-Bordeaux-Paris Motor-cycle Reliability Trial.

No less than sixty-five entries have been received for the Paris-Bordeaux-Paris reliability trial for motor-cycles organised by the Auto-cycle Club de France. The weighing-in operation commenced on Wednesday, while the trial proper started at 6 a.m. on Friday, the competitors being sent off in pairs at intervals of a minute, the first day's destination being Tours, a distance of 162 miles.

◆ ◆ ◆

The Paris-Nice-Paris Anti-skid Trial.

The endurance test for anti-skid devices terminated successfully at Paris on Tuesday of last week, when the six competitors all arrived in good condition from their journey to Nice and back, a distance of 2,500 kilometres. These included Samson I. (fitted on a 24-h.p. De Dietrich, three passengers), Samson II. (12-h.p. Panhard, three passengers), Samson III. (20-h.p. Chenard Walcker, four passengers), Billet (20-h.p. Prunel, five passengers), Herault (14-h.p. Renault, five passengers), and Fouilloy (16-h.p. Mors, three passengers). The tyres, which were all in excellent condition after the long run, were carefully photographed, and the judges are now preparing their report.

◆ ◆ ◆

Motor-Boats on Lake Lucerne.

A series of motor-boat races will be held on Lake Lucerne in July next. On the 23rd there will be a race for cruisers, and on the 24th one of 114 kilometres for boats of a length not exceeding eight metres.

◆ ◆ ◆

Motor-Cars in Italy.

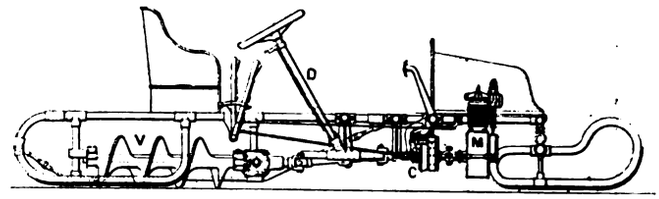
According to a return lately issued, there were only 1,870 motor-cars in use in Italy at the commencement of the present year. The largest number are in the province of Turin, which is responsible for 350 of the total, Milan province coming second with 239 and the province of Florence third with 169.

◆ ◆ ◆

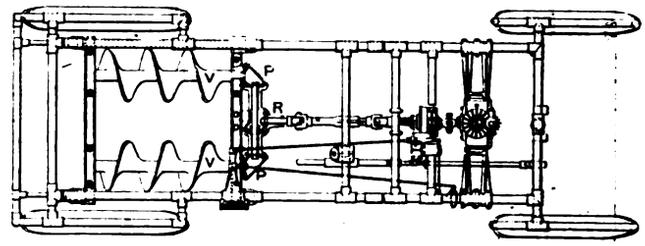
The Herkomer Trophy.

The Bavarian Automobile Club has resolved to postpone the competition for the Herkomer trophy until next year. Owing to the lateness in getting out the invitations and to the fact that the leading automobile clubs are just now engrossed in preparation for the Gordon Bennett race, it is felt that the competition could not be organised on a scale befitting its importance.

◆ ◆ ◆



The Nice-Rome Tour.



The tour from Nice to Rome, organised by "La France Automobile," commenced on Monday by a preliminary consumption test over a 80 kilometre course in the neighbourhood of Nice. Tuesday was devoted to brake trials, while on Wednesday a start was made for Turin, a distance of 212 kilometres. Altogether 22 entries were received for the tour.

◆ ◆ ◆

A Motor Sleigh.

"La Vie Automobile" in a recent issue describes a motor-sleigh which has been designed by M. Nez. Vigneti, of Paris, which, it is stated, is being built for the Russian Government for military transport purposes in the Far East. Illustrations showing an elevation and plan of this novel vehicle are given herewith. Propulsion is effected by means of the two parallel endless screws V V, which obtain a grip on either snow or ice and thus drive the vehicle forward. These screws are actuated by the bevel wheels P P, which receive their motion from the central shaft R. This communicates with the clutch C and the motor M, located in the fore part of a tubular frame. The other organs are practically the same as those of a petrol-driven

motor-car, there being brakes, steering wheel, and change-speed gear, etc. The frame of the vehicle itself is mounted on U-shaped steel runners. The illustrations show a single-cylinder engine, but the sleigh under construction will have a 10-h.p. two-cylinder motor, which, it is stated, will give the vehicle a speed of from twenty to twenty-five miles per hour over a frozen surface.

A LAD was summoned at Southampton under the Motor-Car Act for driving a motor-cycle in Shirley without a licence. It appeared that the lad had the machine out for an hour on hire from a Shirley agent, and the Chief Constable said he did not wish to press the charge, but he added that if the law had allowed him to do so he would have brought the owner of the machine to Court for letting it out to an inexperienced lad.

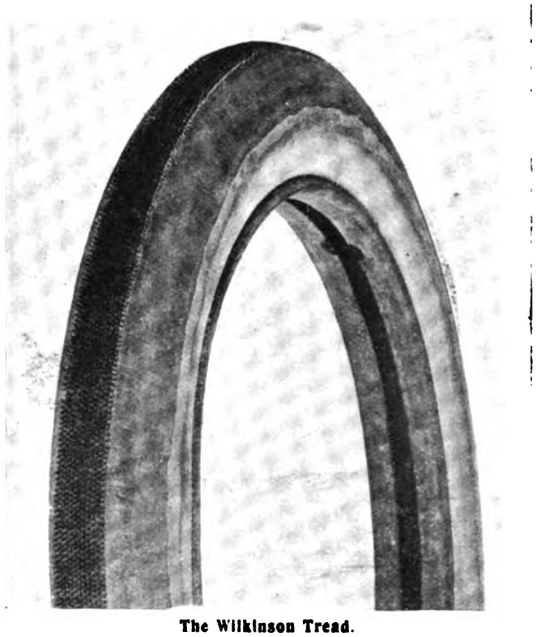
THE SIDE-SLIP TRIALS.

ON Monday the Side-slip Trials of the A.C.G.B.I. commenced in a burst of sunshine which, having been continued for more than a day, has given a new pleasure to those whose duties were with the cars. Each day during the present week a run will be made, the total, including next Monday's, mileage being 850 miles. Thus some idea of the durability of the devices will be obtainable before the actual tests will take place. The behaviour of the cars not being in question, any number of stops are being allowed provided a note be made in the record sheet of the exact time occupied by each, so that the average speed of the car for the day's run may be ascertained. Every renewal, adjustment, or examination that is made of a non-slipping device must be noted by the Observer, and in cases of mishap as full details as possible must be recorded. When a device is renewed or a breakdown to the car renders it unable to complete the journey the Observer must either remain with the vehicle the whole time repairs or renewals are being undertaken, or he must have the device removed from the wheel and himself take possession of it and return with it to the Automobile Club, handing it to Mr. Basil Joy, the technical secretary. Disabled covers or tubes must be taken possession of in a similar manner. At stopping places, such as where stops are made for lunch, the Observer is expected not to allow the car to be out of his sight, so that no opportunity may be afforded the driver or other person to interfere with the device. Record-sheets have to be handed to the technical secretary, who attends at the Locomobile garage in Sussex Place, South Kensington, each night.



In our issue of the 9th inst. we gave the list of entries up to date. Altogether sixteen were received, and of these eleven actually started on Monday morning. Unfortunately the car on which Mr. Cavendish's device was fitted was stolen, with the result that the entry had to delay its start till Tuesday. Those that actually started were as follows:—

Official No.	Name.	Price for a tyre 810 by 90.	Nature of device.
1	Mr. Samuel Butler	£4	Flat discs on tread held on by steel stems passing through the cover.
2	Mr. H. S. H. Cavendish	£15 per car	Single disc running on ground between back wheels.
3	Mr. W. Hunt ...	£15 15s. per car	Double roughed discs running on ground between back wheels.
4	Mr. W. Maitland Edwards	£4 19s. per tyre	Detachable leather band fitted with steel segments riveted thereto.
6	Mr. Alex. Nicholson	£16	Steel blades on back wheels with springs; not touching tyres and lifted from contact with road by lever.
7	Mr. Mark Vivian ...	£2 2s. per tyre	Tread consisting of alternative sections of hard and soft rubber.
8	Wilkinson Tyre and Tread Co. ...	£3 15s.	Fine steel wire staples embedded in tread.
9	W. Jenkinson and Co.	£6 per wheel	Detachable leather ribbed cover.
11	Sainsbury's Anti-Skidders	£7 10s. per car	Spring fork carrying blades each side of tyre, supported on rim.
12	L'Empereur ...	£4 per tyre	Steel plates connected by links fitted on tread, detachable and kept on by inflation of tyre.
14	The Parsons Non-Skid Co.	£4	Detachable chains on tread.
15	The Civil Service Motor and Cycle Agency, Ltd. ...	£5	Detachable leather cover fitted with steel studs (Billet).

Unfortunately Messrs. Rourke and Horsborough's device, which consists of double discs running on the road between the back wheels, was not ready in time to be started with the others.

Monday's run was to Margate and back by way of New Cross and Deptford, where tram lines had to be negotiated. Across Blackheath the route was up Shooter's Hill, followed by a deep drop to Welling. From Dartford, the road by Greenhithe and Northfleet was taken, and thence something like dust was met with in passing through Rochester, Chatham, and Sittingbourne. After a brief halt at the Clock Tower at Margate, the cars returned by the same route, reaching London again about seven o'clock. The cars made good running, and the Observers on Nos. 7, 8, 11, 12, 14, and 15 seemed well satisfied with the performances of the various devices with which they were fitted.

Tuesday's run was by way of Hammersmith through Colnbrook, Slough, Maidenhead, Reading, Savernake Forest, to Marlborough. Several tyre troubles were encountered. On Wednesday another pleasant day's journey was experienced; on Thursday the trip was to Birmingham, thence on Friday to Nottingham, the vehicles being due back in town on the 23rd. Next Monday the endurance trial will be completed with a trip over the tram lines of West London. Tests of power absorption and resiliency will follow, the latter taking place on Thursday at Barnet. On the 7th prox. the side slip trials will take place on the track at the Clement-Talbot Works at Ladbrook Grove, London, W.

The Wilkinson Tread.

Following the descriptions of some of the devices that have appeared in previous issues we illustrate herewith the Wilkinson non-skidding tread, which is taking part in the trials. The wires are pricked on the slope and the treads are run with the wires pointed toward the back of the car, so that in running there is an inclination for the wires to cushion towards each other. They also offer the least resistance to the running. The wires are made of hardened steel, and are set in staples. It is claimed that these treads prevent side-slip, and they are a great protection to tyres against cuts and punctures.

AT the meeting of the Hotchkiss Ordnance Company in London on Tuesday, Mr. C. F. Parsons referred to the way in which the automobile industry had been tackled. The company had found a firm to purchase the entire output of cars and take the whole risk. He believed that in the current half-year they would complete cars to the value of £100,000, and the greater part of that output was already, he believed, sold in advance.

THE HIGH-TENSION IGNITION SYSTEM FOR PETROL MOTOR-CARS.

By J. W. Frings.

(*Continued from page* 147).

E. M. F. (Electro-motive force).—Practically equivalent to pressure. The term E. M. F. is used to denote that which moves or tends to move electricity from one place to another. The unit of electro-motive force is the volt, the simplest illustration of the term being that an ordinary ignition accumulator, which consists of two cells in series, gives a pressure, when fully charged, of about 4·4 volts, or 2·2 volts per cell.

Resistance.—That property of bodies by which they obstruct the steady flow of electricity through them and resolve into heat the energy of the current which is passing. The internal resistance of a battery is due to this property acting in the liquid of the cell which forms part of the path over which the current is flowing. The external resistance of the circuit is similarly due to this property acting in the conducting medium, the wiring, in the external circuit. Resistances are also occasioned by imperfect contacts at points. Such resistances are affected by pressure, for when the two surfaces of a conductor, which through

Signor Storero on a 1903 Fiat Racer—one of the drivers in the Italian Gordon Bennett team.

dirt, or oxidation, etc., are making an indifferent contact, are forced into more intimate contact the current passes more freely. The resistance of a conductor is inversely proportional to the area of its cross section, and directly proportional to its length. There is also the specific resistance to be considered, the various conductors varying widely in their capacity for conduction. Copper has a very low specific resistance, the resistance of lead is approximately twelve times as much as that of copper; and iron about eight times as much.

Ohm.—The ohm is the unit of resistance, and is practically illustrated by stating that 100 yards of ordinary telegraph wire has roughly the resistance of one ohm. As the resistance is inversely proportional to the cross sectional area, a wire having a resistance of one ohm would, if its diameter were doubled, have a resistance of only ·25 ohm. The internal resistance of an accumulator is practically nil, whilst that of an ordinary dry cell is about ·5 ohm. With four such cells in series the internal resistance would be about 2 ohms, consequently short circuiting would not do very great injury beyond wasting the current, at a comparatively slow discharge rate.

Magnetic Field.—The force with which a magnet attracts or repels another magnet or a piece of steel or iron is called magnetic force, the amount of the force exerted being greatest at the poles of the magnet, and it is inversely proportional to the distance at which it is acting. The immediate neighbourhood of a magnet is called the magnetic field, in which magnetic induction takes place.

Condenser.—This is an apparatus consisting of alternate sheets of tinfoil and paraffined paper—insulation—used in connection with an induction coil, into which the current flows when the circuit is broken. The effect of this is to suppress the inverse current at make and to strengthen the direct electromotive force at break.

The accumulator and coil system of ignition is called high tension owing to the fact that electricity of high potential difference is used for the actual ignition, the spark which fires the charge being produced from the induced current circulating in the secondary winding, which has a potential difference of some thousands of volts.

The principal members of the system are the battery, coil (and condenser) and the sparking plug; the other integral portions being the contact breaker, switch and wiring ("leads" and "returns"). Dealing with them in the order given above, I will first take the battery, of which in common use there are two types, presenting distinct features:—Dry batteries (primary), and accumulators (secondary batteries) or so-called storage batteries.

Dry Batteries.—These are usually modifications of the simple voltaic elements—zinc and carbon—of constant or non-polarisible type, filled with some material to prevent the liquid electrolyte from spilling. These cells have a larger capacity for current, size for size, than accumulators, and as the internal resistance, when four are coupled in series, is reasonably high, the possibility of damage by "shorting" is not great. As, however, the energy developed depends entirely upon the consumption of zinc, which forms one of the elements of the cell, and this is changed (by chemical decomposition) without possibility of restoration to its original form by further chemical or electrical action in the cell itself, it follows that when the cells, or series of cells, generally four, which form the battery have expended their latent energy in giving off current, the battery is useless and must be discarded, as it would be almost as costly to renew the zincs and remake the cells as to furnish new ones. The initial cost of the dry battery is far less than that of an accumulator, and it is capable of standing rougher and more irregular treatment than the accumulator. The renewal, however, of dry batteries, as against the cost of recharging accumulators, would make the primary batteries twice as costly as the other in continued use. The voltage of dry cells is generally about 1·25 each, so that the battery of cells gives normally about five volts. It is possible with some forms of primary batteries to partly renew the vitality of the cells by recharging from a dynamo, chemical reactions taking place to a small degree in the battery under the influence of the powerful current from the dynamo which enable the battery to give out for a limited time a fair discharge. Practically speaking, however, when a set of dry cells fails to give a useful working current it may be discarded.

(*To be continued.*)

We understand that the Thames Ironworks Company is about to build steam lorries.

The Antwerp Automobile Club has decided to hold a series of 500 metre speed trials, with standing start and stopping finish, on May 8th.

The motor-boat race at Monaco for the Prince de Monaco Cup was run off last week, the winner being the Georges Richard boat "Trefle à Quatre." The distance was 2,852 metres, and this was covered in 4 m. 17 sec.

It is announced that the French State Railway authorities are about to inaugurate services of motor trains. M. Purrey, of Bordeaux, is designing the cars, each of which is furnished with its own steam motor, and has accommodation for thirty-six passengers. They are designed to attain a speed of sixty miles an hour.

HERE AND THERE.

AN automobile club has just been formed at Toulon, France.

THE Cardiff Corporation have acquired two motor-wagons from Messrs. Mann, of Leeds.

A POWERFUL racing machine, the nominal horse power of which is said to be 100, has just been completed by the Buffum

The "Central Greyhound" 100-h.p. Racer.

Manufacturing Company, of Abington, Mass., for the Central Automobile Company, of New York. It will be noted from the accompanying illustration that the car is somewhat like the Winton Bullet in appearance. It is, however, longer and lower (only clearing the ground by about six inches), and of apparently greater power. The frame is of channel steel, the suspension being by means of spiral springs. The power is supplied by an eight-cylinder opposed horizontal engine, provided with four carburettors and mechanically-operated inlet valves. The radiator is cooled by means of two fans. The car has no change speed gear. At the rear end of the clutch shaft is fastened a bronze mitre pinion meshing with a similar pinion on the countershaft which carries the differential. From the countershaft the power is transmitted to the rear wheels by the usual side chains. The wheel base of the vehicle is ten feet and the overall length thirteen feet. The car, which weighs 2,300 pounds, is to be entered in all American road or track races during the coming season for which it is eligible. It is to be called the Central Greyhound, and, judging by its appearance and enormous engine capacity, the name is an extremely suitable one.

THE Newport (Mon.) Watch Committee has refused to withdraw its application for the ten mile speed limit.

THE latest cycle trader in Ireland to go into the motor-car business is Mr. J. Wright, of Hill Street, Newry.

MESSRS. P. AND T. MURPHY, of Clonmel, now undertake the repair of motor-cars as well as the design of automobile bodies.

THE Eastbourne Town Council are inviting, through our advertisement columns, applications for the post of traffic manager of the Corporation motor-omnibus service.

THE Pope Motor-Car Company, of Hartford, Conn., U.S.A., has recently received an order for ten four-cylinder petrol cars for shipment to Japan, for the use of the Japanese army.

UNDER Section 10 of the Motor-Car Act, about 2,000 sign-posts would be required in the area of the Derbyshire County Council, which has decided to take no action in the matter for at least a year.

REFERRING to the recent motor-car exhibition at the Agricultural Hall, the "Motor Age" of Chicago, says:—"The show is well managed, and in some respects is more popular with the general public than the Crystal Palace show, one reason being that it is held in a building more generally accessible. Probably, also, the nearness of spring and country motoring has created a buying spirit not prevalent at the time of the other great show."

A SECOND car is to be purchased by the A.C.G.B.I.

WHY is it that the petrol tank frequently develops an aching void when within ten miles of a base of supplies?

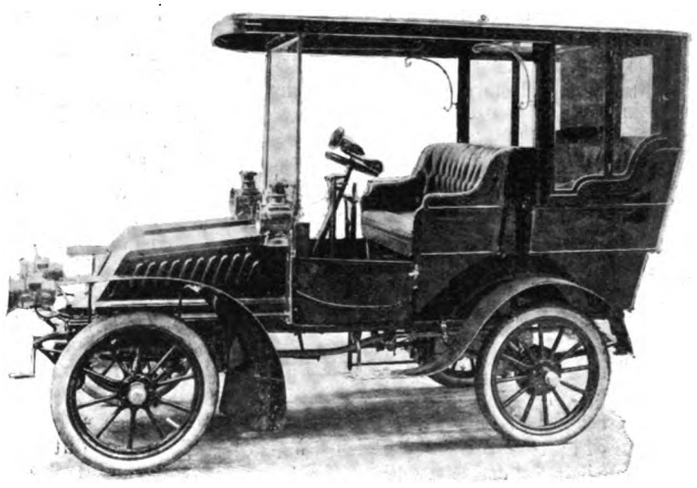
AN electrical trolley motor-omnibus service is about to be started between Wermelskerchen and Dhunn, Germany.

AGENCIES have been established at Taunton and Weston-super-Mare by the Bridgwater Motor Company, Limited.

THE Prince of Wales, having concluded his visit to Windsor Park, returned to town by motor-car to Marlborough House.

THE mayor of St. Louis, U.S.A., has appointed a special committee to welcome the automobilists to the city on the occasion of the projected big tour.

THE life of a motor-car is measured by the excellence of its manufacture, but the years of usefulness of the best automobile in the world can be shortened by misuse.



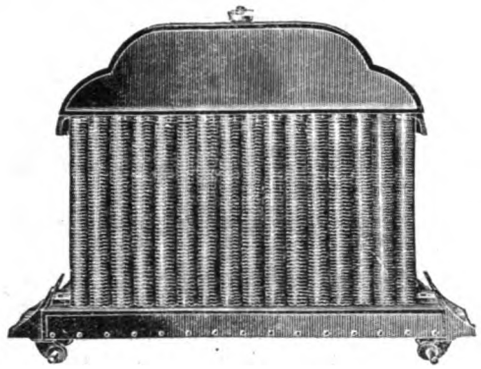
MR. G. W. BURNELL has removed from Lower Brook Street to Albion Street, Rugeley, where he will have every facility for the repairing of motor-cars and cycles, and storage room for twenty cars.

BECAUSE he competed in unsanctioned meets at Savannah, Ga., on February 25, and at Birmingham, Ala., on March 8, Barney Oldfield has been suspended by the Racing Board of the American Automobile Association.

MR. HARRY SNOWDON, A.M.I.E.E., the manufacturer for the United Kingdom and Colonies of the Nodon Patent Electric Valve, has removed from Queen Victoria Street to larger offices at Balfour House, Finsbury Pavement, E.C.

THE Du Bois Company, Limited, who have taken up the London Agency for the Dennis cars, have opened a depot at 4, Princes Street, Hanover Square, W. The premises include not only a showroom, but a large lift gives access to the basement, where cars may be washed or repaired.

THE first loads of merchandise conveyed by motor lurry in the Lake District have been delivered at Ambleside from Windermere. The directors of the Lake District Road Traffic Company witnessed the power of the lurry as it ascended some of the steep gradients leading towards the Kirkstone Pass.



A 10-h.p. De Dion with Detachable Brougham Top.

A PROPOSED tax of £3 on every automobile or other vehicle not drawn by horses and used exclusively for business purposes, and £6 on every such vehicle used for pleasure driving or the transportation of passengers, was discussed by the municipal authorities of Montreal at a recent special meeting of the city council called to consider proposed amendments to the city charter. Nothing can be done in the matter until it reaches the Provincial Legislature. In all probability several meetings will be held to discuss the proposed tax, those interested in motoring having resolved to fight against it.

As mentioned in a recent issue, the Coventry Plating and Presswork Company, Limited, have lately brought out a new radiator for use in connection with the water circulation of petrol cars. The feature is the employment of a tube claimed to be 40 per cent. lighter than those usually employed, to which

radiating fins of aluminium are fitted in a special way. The fins are in metallic contact with the tube, they being held in position by a self-locking arrangement dispensing with the use of solder. In addition to their extreme lightness, the makers claim an increase in efficiency, they being able to guarantee the same cooling effect with 15 per cent. less tubing, in feet, than used in the ordinary rubber pipe radiator.

SOME experiments are about to be made in Antwerp with a new dust-laying preparation known as "Goudroginite."

SIR GILBERT CLAYTON EAST will welcome the members of the Berkshire Automobile Club to his place at Maidenhead on the 28th prox.

THE opening run for the season of the Western Section of the Scottish Club will be held to-day (Saturday) to the Dreadnaught Hotel, Callander.

FIELD-MARSHAL SIR E. WOOD, V.C., Commanding 2nd Army Corps, availed himself of the services of the Motor Volunteers on the occasion of his visit to the defences of Dover.

THE Continental Caoutchouc and Gutta-Percha Company draw our attention to the fact that their new treads are stamped "Continental Protector" in combination with their well-known trade mark.

MESSRS. MONTAGUE HAWNT AND COMPANY have been appointed sole wholesale agents for the United Kingdom for "Valvoline" and "Wilburine" oils, both of which have attained a large degree of favour among motorists.

THE Hitchon Gear and Automobile Company, Limited, has been registered with a capital of £10,000 to adopt an agreement with Mr. A. Hitchon for the working of Patent No. 18,460 of 1901, for improvements in transmission appliances in connection with automobiles. The registered office is at Moscow Mill, St. Oswaldtwistle, near Accrington, Lancashire.

MESSRS. JOSEPH LUCAS, LIMITED, send their catalogue for the season, in which illustrations are given of some good styles of headlights, including the "King of the Road," with its patent locking device. They have also a new pattern back light with white side lens and ruby back. The list also describes a large selection of motor-horns and fittings, motor pumps, motor outfits, jacks, lubricators, etc., as well as the firm's motoilers and their well-known Wells Lucas motoil and auto grease.

MESSRS. SALSBURY AND SON have brought out "Gre-Solvent," a useful preparation for cleaning the hands after doing repairs or adjustments to the engine, tyres, etc. This Gre-Solvent will thoroughly cleanse the hands, leaving the skin quite clean and soft. The "Dazlit" metal polish, also introduced by the firm, is made according to a formula upon which Messrs. Salsbury and Son, Limited, have made metal polishes for years for their own use, and having tried all descriptions of metal polishes in the business, they now confidently assert that they have never found any to equal this. There is no acid or grit of any description in it, and it can be used with perfect safety upon the most delicate materials.

MOTOR-CYCLING NEWS.

SIMULTANEOUSLY with the side-slip competition for cars, a similar trial of devices for use on motor-cycles will take place on the grounds of the Talbot Works, Notting Hill Gate, W., on the 7th prox.

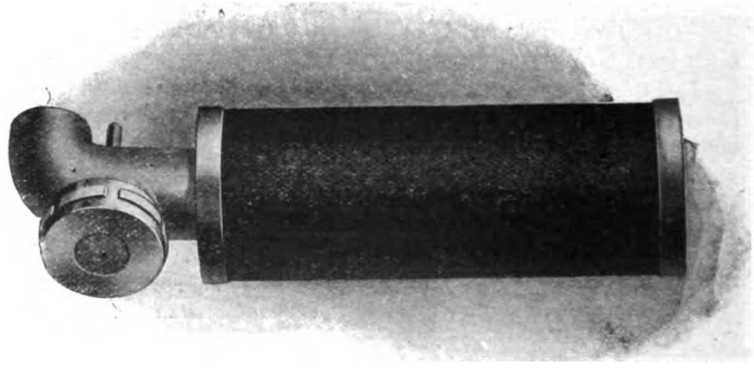
◆ ◆ ◆

THE Auto-Cycle Club will hold a hill-climbing competition on May 14th, the entries being divided into the following classes:—(1) Machines with engines having a cylinder capacity of 70 by 70, or the equivalent volume swept out; (2) Machines with engines having a cylinder capacity of 76 by 76, or the equivalent volume swept out; (3) Machines with engines having a cylinder capacity of 80 by 80, or the equivalent volume swept out; (4) Machines with fore-carriages, side-carriages, and trailers, carrying two passengers. The location of the course will not be announced until the last minute, and the event will be confined to members of the club. Two silver medals will be given in each class, provided there are sufficient entries, whilst a gold medal will be given for the most meritorious performance of the day.

◆ ◆ ◆

A COMBINED run of motor-cycling clubs will be held at Great Yarmouth on the 28th prox., on the suggestion of the Auto-Cycle Club.

◆ ◆ ◆



THE Auto-Cycle Club have had in hand the case of the motor-cyclist who was summoned at the Wallasey Petty Sessions (near Birkenhead) and fined 5s. for not exhibiting a red light at the rear of his cycle, their contention being that a motor-bicycle only requires the ordinary light. The club now understands that the magistrates' clerk, on looking further into the matter, has come to the conclusion that the club's contention is right, and that no further convictions will be recorded in such a case. In the case of certain motor-cyclists who had been summoned, no further proceedings are to be taken.

◆ ◆ ◆

THE Hereford Automobile Club has decided to hold a hill-climb for motor-cycles at Dinmore Hill on the 3rd May.

◆ ◆ ◆

THE accompanying illustration depicts the exhaust box fitted to the "Ariel" motor-cycles. It is of special construction, and is so designed as practically to deaden the noise of the explosion. The device consists of three circular tubes telescoping into each other, with holes drilled in various positions for allowing egress of the exhaust gases. The makers claim the "Ariel" machine to be one of the quietest—if not the quietest—motor-

bicycle upon the market. As will be seen from the illustration, a valve is fitted (operated by a small lever close to the saddle in reach of the rider), which, when open, releases the exhaust gases direct into the air without passing through the exhaust box. This, however, only need be used when climbing exceptional hills. The makers, the Ariel Cycle Company, Limited, point out that it is also very useful in effectually disposing, for the time being, of the motor cyclist's *bête noire*, *i.e.*, a yapping dog.

SPEED CALCULATION.

AN ingenious and exceedingly convenient method of finding the rate per mile travelled by a motor-car or other vehicle has been devised by Mr. E. D. Winans, of the American Darracq Automobile Company. It takes the form of a table, which is printed on a card, with a key, by means of which a motorist can tell at a glance the rate of speed for any given number of seconds. The table is a double one, the speeds up to a mile a minute being read from the columns at the left hand side and top, and those above that—*i.e.*, at slower than a mile a minute—being read inversely, or from the figures in the little squares.

The table and accompanying key are as follows:—

	0	1	2	3	4	5	6	7	8	9
0	8	3600 1 hr.	1800 30.00	1200 20.00	900 15.00	720 12.00	600 10.00	514 8.34	450 7.50	400 6.40
1	360 6.00	370 5.27	300 5.00	277 4.37	257 4.17	240 4.00	225 3.45	212 3.32	200 3.20	189 3.09
2	180 3.00	171 2.51	164 2.44	156 2.36	150 2.30	144 2.24	138 2.18	133 2.13	129 2.09	124 2 04
3	120 2.00	116 1 56	112 1.52	109 1.49	106 1.46	103 1.43	100 1.40	97 1.37	95 1.35	92 1.32
4	90 1.30	88 1.28	86 1.26	84 1.24	82 1.22	80 1.20	78 1.18	77 1.17	75 1.15	73 1.13
5	72 1.12	71 1.11	69 1.09	68 1.08	67 1.07	65 1.05	64 1.04	63 1.03	62 1.02	61 1.01

The left hand column indicates the tens—the upper cross column the units of the speed per mile in seconds. Where these columns intersect will be found the speed per hour. Thus 45 seconds to the mile equals 80 miles per hour, that being the figure at the intersection.

When the speed is over a minute to the mile, take the figure denoting the time in seconds and follow out reversely. The result will show the rate per hour; thus 1·20 to the mile is 45 miles to the hour.

THE "UTILE-SIMPLEX" CAR.

THE other day we had an opportunity of making a short trial run on a novel four-seated car which is being introduced by the Utile Motor Manufacturing Company, of Kew Gardens, the novelty lying in the fact that no gear-box, in the usual sense of the term, is employed. In outward appearance the little car resembles an ordinary cardan shaft driven tonneau. The single-cylinder 8-h.p. engine is on the lines of the well-known De Dion, the valves being interchangeable therewith. The crank case is, however, of much larger dimensions than usual, to admit of an extra-large half-speed cam shaft, an intermediary pinion being provided to cause the crank and cam shaft to rotate in the same direction, the object of which is dealt with below. By means of a wedge-shaped piece inserted between the exhaust valve stem and the cam-controlled valve lift, and actuated by a lever on the steering standard, the lift of the exhaust valve can be varied, a notable elasticity being thereby imparted to the engine. As already mentioned, no gear box is fitted to the car, 90 per cent. of the running being done on the top direct gear. For starting purposes and for use on very steep hills a second speed is made available by utilising the enlarged half-speed shaft. The accompanying illustration gives a view of the *chassis* from below. From this it will be seen that both the crank shaft and the cam shaft have friction clutch members fitted at their rear ends, and another clutch member, which corresponds with both of these, is mounted on the forward end of a short shaft from which a universally-jointed shaft extends to the live axle. The short clutch-shaft is carried by a bracket pivoted on the engine between the two clutch members, and also on a cross piece on the frame, in such a way that the clutch can be withdrawn by a pedal in the usual way sliding it endwise, and that it can then be swung over so as to come in line with either the crank shaft or the cam shaft, this being done by a lever on the steering standard corresponding to the change-gear lever. Two forward speeds are in this way obtained, and on the high gear there is a direct drive from the crank-shaft to the rear axle. In this very simple manner all that is necessary in the way of speed-reduction gear for a light vehicle is secured, and in addition to this, the mechanism is in every sense self-aligning, and the transmission losses under ordinary conditions are reduced to a minimum. Even when the cardan shaft is being driven by the cam shaft, the former shaft lies at but a small angle from the straight, owing to its length.

Underneath View of "Utile-Simplex" Car.

A single central radius-rod, which is fixed to the casing enclosing the live axle, is hinged at its forward end to the frame just above the clutch shaft, and also relieves the torque of the backaxle.

During the course of the recent Exhibition at the Agricultural Hall, the car took a load of four passengers up Pentonville Road, N. We have had evidence, too, that the method of utilising the cam shaft as the low gear works excellently in practice. The clutch member on the short shaft connected with the cardan is a double one. On the top gear it surrounds the clutch member on the crank shaft, while on the lower gear it goes inside the member on the cam shaft.

H.R.H. PRINCE HENRY OF PRUSSIA has brought over his motor-car to use whilst in England, and to show his regard for law and order promptly registered his car No. 4761A., obtaining a regulation number plate from Messrs. Gamage, Limited.

CORRESPONDENCE.

A USEFUL HINT REGARDING TYRES

To the Editor of *The Motor-Car Journal.*

Sir,—May we be allowed to give your readers the benefit of a little matter of tyre practice which one of our directors has recently found to be of the greatest utility? The idea is simply an adaptation of the method of using up of hitherto deemed worn-out covers. Some time ago Mr. Paul Meyan pointed out that he used old outer covers superimposed on his ordinary covers; we believe his method was to use old covers of a larger initial size than his covers proper, and attach them by inserting them between the latter and the rims. A contemporary of the *Motor-Car Journal* now points out that an old and therefore stretched cover of the same initial size as the normal cover may be used by cutting off its edges and simply placing it over the latter when this is deflated, and then blowing up hard; our director, however, found this method of attachment not sufficiently secure.

The obvious extension of the idea was to sew straps to the old covers and secure these to alternate spokes in a manner that will suggest itself to anyone. We can assure you the result is most surprising and satisfactory; any saddler can sew on the half dozen or dozen straps for a few shillings, and the old cover so secured is perfectly firm. Even if it is badly cut the cuts do not gape (though it is advisable to place canvas behind them), and of course there is no wearing surface equal to that of a properly vulcanised rubber one. Owing to the severance of continuity between the attached cover and the ordinary cover puncturing objects that pierce the former are turned at the surface of the latter. We have a sharp nail three inches long that was picked up at the first trial, pierced the outermost cover and then simply passed in between the two for a distance of a couple of inches, where it was tightly held. We are convinced that this method of using up old covers will be more than a boon to every driver who makes use of it, and we trust this will be our excuse for the length of our communication.—Yours truly,

The Cambridge Autocar Co., Ltd.

THE CAPACITY OF ACCUMULATORS.

To the Editor of *The Motor-Car Journal.*

Sir,—Owing to the French manufacturers of accumulators marking batteries at exactly double their true capacity, the custom has arisen in this country of calling a 10 ampere-hour battery "20 ampere-hours capacity." The trade always ask for a 20 a.-h. accumulator, meaning cells containing one positive and two negative plates, the positive plate being of such an area that it cannot possibly give much more than 10 a.-h. capacity. We are sometimes told that though the capacity may be lower at a continuous current discharge rate, it is much higher on intermittent ignition work; this is true, as, whilst on continuous discharge work, the plate will give 8 a.-h. capacity, and on ignition one may safely reckon 10 to 12 a.-h. This, however, is not double the capacity. To show the absurdity of marking 10 a.-h. cells at 20 a.-h., there are price lists in circulation at the present moment containing the following:—Capacity, 20 a.-h.; charging rate, 1½ amperes for eight hours. This is equivalent to 12 a.-h. being put into the battery when charged, and yet you are informed you can get out of it 20 a.-h., which is absurd.

Having been compelled to adopt this absurd method ourselves prevent confusion when corresponding with the trade, who ask for and order 20 a.-h. accumulators as a general term only, we now think it is quite time that accumulators should be marked by their true capacities and thus save considerable confusion when they are taken to be charged. In our new price list for 1904, each accumulator is marked at the capacity it will give when discharged at its normal rate continuously on a resistance. We recently saw a note to the effect that the capacity of the usual 20 a.-h. battery had been increased to 25 ampere-hours, which is only another instance of perpetuating a fable. In all accumulators made by us, we (in common with several other makers in this country) have stated the correct capacity on continuous current discharge; but in selling French types of cells in competition with French manufacturers I believe we have all had to adopt the French capacity rates for our own protection. For instance, in our last year's list we give an accumulator as 13 a.-h. on continuous discharge work and 20 a.-h. on ignition work.—Yours truly,

Peto and Radford.

La France] Motoring in Tunis.—The Natives at Medjez el Bab inspecting the Modern Means of Locomotion. [*Automobile.*

STEAM CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—As a user of paraffin burners for the past three or four years, my experience will doubtless be useful to your correspondents "Locomobile" and "Steamer" in your issue of the 9th inst. I found that my Clarkson burners gave very good results if properly attended to, but they apparently do not do themselves justice working under a Locomobile. The Cremorne burner, owing to its compactness, is, however, much more readily adapted to this type of car, and after fifteen months' experience of this burner on my car I find no tendency of the jet to clog, and can average seventeen miles an hour over ordinary roads. I should mention, however, that I took the precaution to have a strainer fitted on the oil pipe, which, no doubt, lessens the risk of clogging. I also fitted a steam jet, finding this necessary in order to obtain full power from the burner

Digitized by Google

without smoking. Perhaps the makers will explain why this is necessary, as a steam jet is not economical.

My experience of injectors is that they are not much use on light cars. They are wasteful in steam, and, unless used constantly, are a failure. I am looking out for a good steam touring car to seat from four to six people and capable of travelling at least one hundred miles on one charge of fuel.

I would like some advice on the boiler question. The Miesse and the White have flash boilers. What is the life of these boilers; perhaps some of your readers will give me their experience? It seems to me that a water tube or tubular boiler would be more serviceable for touring.—Yours truly,

LOCOSURREY.

TYRES AND CARBURETTORS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—There has been lately a large correspondence in the motor papers concerning pneumatic unreliability. I have this year had my tyres (810 by 90), although in good condition, fitted with extra treads by Messrs. Capon Heaton and Company, Limited. I thought it would be useful information that, contrary to theory, this has not affected either resilience or speed. Moreover, the quality of the rubber is so good that it does not cut, and it would now take a very formidable instrument to puncture. My car is a fairly heavy one, and I attribute my record of "no punctures on motor tyres up-to-date" to the fact that I keep my back tyres up to 90 lbs., and the front to 80 lbs.

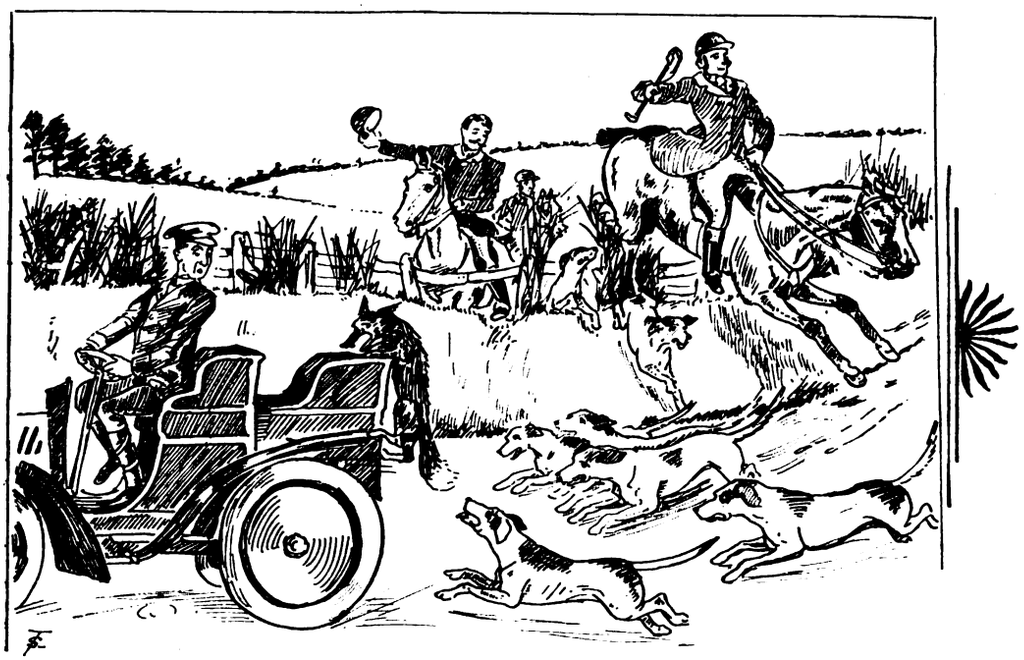
Users of Longuemare carburettors will find it a great improvement to fit a shutter (hinged) on the air inlet, close to the carburettor. It is easily made by oneself, and in my case I have gained power. The air lever can be left farther open and the shutter will actually govern my engine (Aster).—Yours truly,

THOMAS HALLEWELL.

HIGH SPEED ON THE ROAD.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—On my way back from a trip on my motor-bicycle into Bedfordshire yesterday, I had come down Barnet Hill and was just getting to the top of the rise where the new park is, when a huge towering car came past me with the roar of an express train at a speed I should calculate of close upon forty miles an hour. I was myself travelling about fourteen miles per hour, and it came past me so fast that it was impossible to read the back number. The car was enveloped in dust and it was impossible to see through the cloud it raised behind for fully a minute, which in itself constituted a serious danger to other traffic. The occupants appeared to be dressed in light fur coats. At the time (Sunday afternoon about 5.5 p.m.) there was a good deal of cycling, motor and other traffic on the road, and it was simply miraculous that the car got through without an accident. I asked two or three cyclists and motorists if they happened to catch sight of the car's number, but they all said they could not, but a cyclist told me that the car was a sixty horse power and belonged to the proprietor of a daily journal, and that the driver was a gentleman who will participate in the eliminating contest. This is the class of driving that has brought about the present Act, and such speed at such a time and in such a place is wicked. It would, however, in this case, be interesting to know whether my informant is correct in his statement as to the owner and driver of the car in question. I hope not, as drivers or owners who use their powerful cars in this manner are the worst type of "road-hog." You can publish this letter if you like, and if I see the car again and get a chance to see its number, I shall most certainly lay information before the police. High power and speed is absolutely useless except for racing purposes, and the use of it on the road only brings stringent laws into force which operate against innocent users of the highways and the real culprits go scot free.—Yours truly,



MOTOR-CYCLIST.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—May I have the use of your columns to bring forward a suggestion to prevent the wicked and reckless behaviour of some motor-car drivers? It is common knowledge that the worst offenders are the irresponsible paid hands (very frequently French), and also, it must be admitted, the "trade car."

I drive fast at times (alas! I too am a victim of Sergeant Jarrott) but always carefully, and the criminal recklessness round corners at cross roads, or when children are about, that is seen makes one wonder the police are so tolerant! My suggestion is that all private owners, careful drivers, should themselves take the numbers and report to the police of the district and, say, to the Automobile Club, any wanton driving. This would make all drivers careful, if their own brethren "gave them away," as at present a policeman is the only person some are afraid of, and in this way much might be done to avert the animosity felt by many of the public, and in some cases, it must be admitted, justifiably, to all motorists, when it was seen that there was a determination on the part of reasonable drivers to put a stop to the scandal which has caused so many fearful accidents, always, or nearly so, from the twin causes, recklessness and carelessness.—Yours truly,

H. ELLIOT PYLE.

"Sanctuary." From the Experience of a Member of the Eridge Hunt.

DELIVERY VANS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—In November last the firm by whom I am engaged purchased a motor-van. The car in question is a 16-h.p., constructed to carry 30 cwt. at speeds up to fifteen miles an hour, for six months, but up to the present has proved a failure, as the list of mishaps I enclose will show. We were thinking of having twelve cars and do away with the horses and carts we are at present using, but I am afraid this has knocked it on the head. You cannot wonder at business people not using cars instead of horses when they see and have trouble the same as this; it is only ruining an industry, and not only giving themselves a bad name, but other makers "who build a good car" also.—Yours truly,

J. G.

QUERIES *RE* WOLSELEY CARS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I should hesitate before admitting such variation in running as Jehunior" describes to be due to variation in the quality of the petrol.

Digitized by Google

It is hardly likely that anything like stratification can take place in the tank under running conditions, and with almost any good spray carburettor the ill effects of heavier spirit are negligible, except sometimes as regards ease of starting. With light inlet springs, however, irregularities due to sticking of valve stems are more noticeable, and they are best kept free by the use of a little graphite on them, conveniently applied by mixing with petrol. It is always an advantage to be able to regulate the air from dashboard, and an addition to this effect is advisable; but if the existing air inlet is fully open, and this is insufficient, it looks as if the jet may have been unduly enlarged. It is hardly likely to have been sent out in this state, though I have known this happen on more than one foreign car. The new automatic carburettor of the Wolseley Company regulates by a vertical piston valve with side slots, somewhat similar to that of the Krebs, but actuated by the pressure of the exhaust on the diaphragm. This should give regulation both to the speed of the engine and the charge it is taking. The new silencer is certainly an improvement, but the gain in this direction cannot be very large, except as regards silence.—Yours truly,

R. W. B.

1904 MERCEDES CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—With reference to the statements made in the technical press during the last few weeks, we should esteem it a favour if you publish the following letter we have received from M. Jellinek-Mercedes giving particulars of the Mercedes cars that we have bought from him, as follows:—

Translation.—"In reply to your letter of the 7th April, I inform you that the whole of the 18-h.p. 1904 carriages with motors giving on the brake about 28-h.p. are manufactured in the new factory at Unterturkheim, near Cannstatt. The 24-28-h.p. and the 35-h.p. are only made in very small numbers. Your carriages are of the 18-h.p. 1904 with motor giving about 28-h.p. on the brake; your 28-32-h.p. giving about 34 to 35-h.p. on the brake; your 40-45-h.p. giving about 45-h.p. on the brake.—(Signed) Jellineck-Mercedes."

In order to still further enlighten the public, we append a complete list of the cars turned out from Cannstatt other than racing cars, with cylinder capacity and brake horse power.

It should be noted that what is known as the 1903 type has the valves on the top of the cylinders, while that known as the 1904 type is similar to the 1902 type with the valves at each side of the cylinders.

It should also be mentioned, however, that none of the 24-28-h.p. or 35-40-h.p. were made in 1903, that they were all made this year and are really the 1904 cars.—Yours truly,

J. E. Hutton, Ltd.

[The enclosed list is confirmatory of that given in our Correspondence columns (page 162) last week.

To the Editor of *The Motor-Car Journal*.

Sir,—With reference to the letter of Mr. Harrington Moore, I am quite prepared to accept the letter that he states he holds, subject, however, to his accepting mine, which I am prepared to show him.

The letter he owns denies mine, I admit, but mine also denies his. I think, therefore, that very little heed need be taken of the statement made by either letter, as seemingly they are somewhat recklessly written, but I would suggest that Mr. Harrington Moore uses his own judgment, and I would ask him whether the 18-h.p., which is 5 mm. less bore than the 24 h.p, would give the same power on the brake? I think he will agree that there is a very grave mistake here.

In France the new so-called 18-h.p. is called 20-26-h.p., which is getting somewhat nearer the mark.

As regards the somewhat cutting remarks as to where my firm get their Mercedes cars from, I would suggest to Mr. Harrington Moore that in all probability the cars that he is selling come through the same source, although he is not aware of it, and the friends whom I have the honour of being in business with probably hold more of the Mercedes stock than he cares to state, although he may know it.

I would suggest that Mr. Harrington Moore writes to Monsieur Jellineck, and he will probably receive an answer to the effect that my statements are correct and that the Cannstatt Company cannot deliver any goods until next autumn.—Yours truly,

D. M. Weigel.

Dust Laying.—In answer to H. L. P., full particulars of Westrumite can be obtained from Westrumite Ltd., Dacre House, Victoria Street, Westminster.

The Balmforth Steam Boiler.—Replying to Messrs. J. Mowlem and Company, Limited, the Balmforth boiler illustrated in our issue of the 9th inst. is made by Messrs. T. Balmforth and Company, Engineers, Luton.

Messrs. Wallis and Watson, of Trinity Street, Leeds, have been appointed sole agents for Yorkshire for the Duryea cars.

CLUBS AND ASSOCIATIONS.

YORKSHIRE.

On April 9th the first meet of the Yorkshire Automobile Club took place at Aberford, where about fourteen cars arrived, their passengers including Messrs. Tempest, Milner, Mr. and Mrs. Jessop, Mr. and Miss Armitage, Mr. and Mrs. Hepper, Mr. Kirk, and Mr. Faiers. Tea was taken at the Swan Hotel.

On Saturday last the meet was at Ilkley, with headquarters at the Middleton Hotel. There was an excellent muster of Yorkshire members to meet the members of the Burnley and District Club, and in all there was a gathering of about sixty persons.

GLOUCESTERSHIRE.

The April general meeting of the Gloucestershire Automobile Club was held at Gloucester. There were present the president, Mr. Algernon H. Wyatt, the hon. treasurer, Mr. F. M. Bostock, and the hon. secretary, Mr. A. Arthur Dale, and a large attendance of members. The President, in opening the proceedings, alluded to what the club hoped to accomplish in the future. After the reading of correspondence by the secretary, a list of gentlemen desiring to become members of the club was presented.

The hon. secretary next read the committee's report. The report was received. The hon. secretary also read his report of the meeting of the Motor Union, which he had attended as one of the club's representatives upon the general committee of that body. The president then addressed the meeting upon the matter of the inconvenience to motorists from unrolled metal left on the highway overnight. He gave instances of his own and others' experience of the danger, referring also to the risks which motor-cyclists ran when suddenly encountering an unrolled stretch of road. He moved the following:—"That this club desires to call the attention of the Highways Committee of the County Council to the unsatisfactory condition in which the roads are left overnight, and more particularly from Saturday to Monday, in several districts in the county where repairs to roads are being carried out, by reason of the roadmen leaving an unnecessarily large quantity of loose stone on the highway, and respectfully requests that steps may be taken to see that all metal placed upon the highway is rolled in before work ceases for the day." The motion was seconded, and after a few remarks of entire approval, the question was put to the meeting and carried unanimously. The President also brought forward two other motions relating to the lighting of vehicles. The first suggested the adoption of a bye-law by the city of Gloucester and the boroughs of Cheltenham and Tewkesbury similar to that in force in the county. The second, which was to be addressed to the County Council, was in the following terms:—"That owing to the increasing number of motor-vehicles on the highway at night this club is of opinion that it would add to the safety of all users of the road if the bye-law at present in force in this county relating to the lighting of timber wagons were extended to every vehicle on the highway at night time." Upon the motion being seconded, a short discussion took place. Put to the meeting, the motions were carried unanimously.

LINCOLNSHIRE.

The third annual dinner of the Lincolnshire A.C., held at the Saracen's Head Hotel, Lincoln, on Saturday, was a success. There were quite a hundred present, many of whom came on cars. Mr. E. H. Arnott drove from town on a 15-h.p. Napier; Mr. Ross Browne, Nottingham, drove his 24-h.p. Georges Richard; Mr. J. S. Sandars drove his 12-h.p. Siddeley, Mr. A. A. Padley had his new De Dion, Mr. C. H. Seely, M.P., was on his 12-h.p. Daimler, Mr. Parsons Wright was on his 6-h.p. Regal, Mr. G. Linnell (Market Deeping) was on his 10-h.p. Wolseley, Mr. Husband (Crowland) was on his 8-h.p. Wolseley, Mr. C. A. Moring was on his 12-h.p. National, Mr. G. Godson was on a 6-h.p. M.M.C., and Mr. C. Nainby, Mr. C. Holland, Capt. J. A. Cole, and Capt. Lyall, with other members, drove parties over.

Sir Hickman Bacon, Bart., presided, and after the loyal toasts gave "The Houses of Parliament.'

In response, Mr. C. H. Seely, M.P., urged that the Parliamentary party had done what was possible in respect to the Act, and he thought that after all there was not a great deal to complain about. Though motorists had not got all they desired, neither had anti-motorists, and he believed that the fact that now all motors were easily identified would prevent the hostility against motorists, because it was easy to ascertain who were responsible for wrongdoing and the actual offender could be bought to book. Apart from the pleasure side of the movement he thought it would affect such engineering centres as Lincoln and be a great benefit to the city. The commercial side was indeed important, and he would impress upon them that the country which was proceeding at the pace of a horse was severely handicapped as against the country where they went at the pace of motors.

Mr. J. D. Sandars, a vice-president of the club, in giving "The county and city magistrates," gave some reminiscences of his experiences with police and magistrates, but outside his own county, where he was never molested. He thought that was because the police and magistrates endeavoured to administer the law sensibly. When, however, the roads were used for "world's records," even in the early hours of the morning, prompt and decisive action was taken and action that did a lot of good. They were fortunate in being able to be on such good terms with the authorities in the county, and he was sure the members appreciated that fact and would do nothing to imperil the trust placed in them.

Digitized by Google

Mr. C. A. Moring, in giving "The Club," said it was the most distinguished of all the provincial clubs. In proposing "The Visitors," Capt. J. A. Cole referred to the extraordinary growth of the club, and the efforts it had made in several ways. As for the dust nuisance, he was pleased to say that a Lincolnshire surveyor was experimenting with some new material and was sanguine of being able to almost entirely eliminate dust.

Mr. Rees Jeffreys gave an entertaining speech, but before doing so apologised for the absence of other London automobilists. He said that Colonel Mark Mayhew was busy that day in the weighing-in of the cars for the Gordon Bennett, and so was Mr. Cordingley, who had determined to run down. He was pleased to say that as a result of the weighing-in there would be three makes in the tests, the Napier, the Darracq, and the Wolseley. He urged them to assist the commercial side of the movement, which would be of great benefit, and the use of motors as 'buses and the like would do a lot of good in finally breaking down the remnant of hostility.

Capt. Mitchell Innes, who also responded to "The Visitors," commented on the excellent relations existing in the county between the police and the magistrates, and he was sure, from what he had seen, that much of that was due to the way the club had gone to work, and the influence and care it had exercised. He had been giving his superintendents practical acquaintance with, by taking them on their rounds, so that they could be able to properly judge both sides.

MIDLAND.

THE opening run of the Midland Automobile Club was held on Saturday last at Stratford-on-Avon. Nearly forty members were present, several of whom subsequently went on to Alcester. The roads were in good condition.

The club will hold a Whitsun meet on the 21st, 22nd, and 23rd May. A special tariff has been arranged with the management of the hotel.

GLASGOW-LONDON RELIABILITY TRIALS.

FOR the Glasgow to London Reliability Trial for touring cars, organised by the Western Section of the Scottish Automobile Club, the following entries have been received:—

Description of Car.	Starting Order Number	Name.
I.—CLASS A.		
6-h.p. Vauxhall ...	8	P. C. Kidner.
6½-h.p. Cadillac ...	21	Anglo-American Motor-Car Co., Ltd.
6-h.p. Light Wolseley	26	Rennie & Prosser, Ltd.
II.—CLASS B.		
12-h.p. Gladiator ...	2	Thomas Shaw, Ltd.
10-h.p. Argyll	4	Hozier Engineering Co., Ltd.
10-h.p. Rykneild ...	7	Rykneild Engine Co., Ltd.
12-h.p. Richardson ...	9	J. R. Richardson & Co., Ltd.
12-h.p. Eagle Light ...	12	Eagle Eng. and Motor Co., Ltd.
12-h.p. Arrol-Johnston...	13	Mo-Car Syndicate, Ltd.
12-h.p. Siddeley ...	17	Siddeley Autocar Co.
12-h.p. De Dion ...	22	J. W. Stocks.
16-h.p. Maxim ...	24	The Lond. Gen. Automobile Co., Ltd.
16-h.p. Crouan	28	F. W. H. Garner.
8½-h.p. Humber ...	29	Humber, Ltd.
III.—CLASS C.		
16-h.p. Sunbeam ...	1	John Marston, Ltd.
14-h.p. Renault 1904 ...	3	Roadway Autocar Co., Ltd.
12-h.p. Argyll	5	Hozier Engineering Co., Ltd.
16-h.p. Argyll	6	Hozier Engineering Co., Ltd.
16-20-h.p. Martini ...	10	H. H. P. Deasy and Co., Ltd.

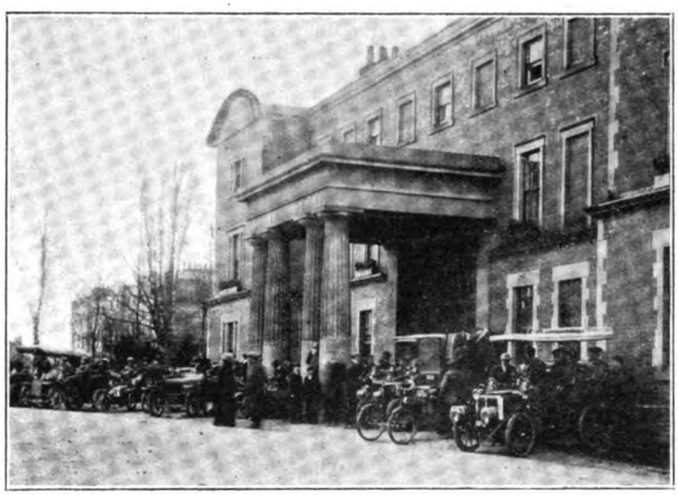
18-h.p. James & Browne	20	James and Browne, Ltd.
18-h.p. Baudouin-Dechamps	23	J. J. Leonard and Co.
20-h.p. Thornycroft ...	25	Thornycroft Steam Wagon Co., Ltd.
18-h.p. Siddeley ...	27	Rennie and Prosser, Ltd.



THE POLICE AND MOTORISTS.

AT the Christchurch Police Court, Charles Pooss, a cycle and motor-car engineer, of the Triangle, Bournemouth, was summoned for having driven a motor in Castle Street, Christchurch, on the 1st April, at a speed which was dangerous to the public. Defendant pleaded not guilty, and, in the course of his evidence, said that when last served with a summons the officer had said "I will have you again soon." The Superintendent of Police observed that, under these circumstances, after such imputation against the constable's character, he would ask the Bench to adjourn the case until another constable could be called. The Bench decided to adjourn the case until the next sitting of the Bench—April 25th.

AT the Hailsham Petty Sessions, William Clee, of Bexhill, was summoned for driving a motor-car at a greater speed than twenty miles an hour on March 27th.—Mr. Lawson Lewis appeared to prosecute, and Mr. F. P. M. Schiller (instructed by Mr. Alan F. Harvey), for the defence. Defendant pleaded not guilty.

Mr. Lewis, in his opening statement, said that on Sunday, the 27th March, Sergeant Allcorn and P.C.'s Waghorn and Upton were on the Dicker-road timing motor-cars, and about 3.15 in the afternoon defendant came past in a motor-car, registered No. D 446. P.C. Waghorn started the "machine for timing motor cars" over a measured furlong, which the car covered in 15 secs., giving a speed of 30 miles per hour. P.C. Waghorn, of Lewes, gave evidence of using the electrical "timing machine," and generally supported Mr. Lewis's statements. Mr. Schiller cross-examined witness as to the watch and apparatus, from which it appeared that the watch was started by Upton, after a warning bell had been rung, and stopped by Waghorn on the car passing him; the watch being started and stopped by the pressing of electric buttons. Sergeant Allcorn also gave evidence. He stopped the car, jumping over a four-foot-six hedge, and putting up his arms in the middle of the road.

Mr. Schiller, for the defence, urged that the watch was no evidence at all, as it had been held that it must be shown by certificate that the watch was accurate. Secondly, the margin of error in stop-watches was very large, especially when they were placed near an electrical instrument. The magnetisation made them wholly and utterly unreliable. The constables were no doubt trying to do their duty with an

The Joint Meet of the Leicestershire, Nottingham, and Derbyshire Clubs at Ashby-de-la-Zouch.

ingenious but incomplete device. He urged that on the preliminary point the evidence failed.

The magistrates retired to consider the point, and on returning decided against Mr. Schiller, who formally asked for a case to be stated. The Bench, after retiring to consider their decision, announced that in their opinion the car at that point was going over 20 miles an hour. They imposed a fine of £5, and costs 12s.

Formal notice of appeal was given.

MR. MOFFAT FORD, of Shaftesbury Avenue, was before Mr. Plowden at Marylebone, on Tuesday, to answer a summons for driving a motor-car in Bayswater Road at a speed exceeding twenty miles an hour on the 2nd inst. Two constables said they stood a quarter of a mile apart in the Bayswater Road on the afternoon in question. By arrangement a signal was given, and both the officers timed the defendant, who was driving a motor-car, with chronograph watches as he passed over the distance named. One watch registered 33½ sec., and the other 34 2-5 sec., or about twenty-six miles an hour. The defendant cross-examined the constable at some length, and then said he should be able to prove that the method adopted by the police in testing the pace at which motor-cars were running was not to be relied upon. Mr. Swindley examined the two watches, and they were fairly correct "in the ordinary way," but he did not consider the methods of the police as good scientific timekeeping. Mr. Plowden said that unless the witness could prove that the calculations of the police in this case were wrong, his evidence was valueless. In giving his decision, the magistrate said he had to decide between the defendant's eighteen miles an hour "metaphorically speaking," and the constables' watches. The methods of the police might be capable of improvement, but for the present they held the field. He saw no reason to doubt either the watches or the constables. They might be wrong as to a fraction—one could not reach perfection in these matters—but they

Digitized by Google

were very much nearer than the man who, "metaphorically speaking," said he was travelling at a speed just within the law. He fined the defendant £3, with 2s. costs.

THE case at the West London Court in which Charles Ashley was summoned for driving a motor-car beyond the statutory speed of twenty miles an hour was again adjourned on Tuesday.

Mr. Wontner appeared for the police, and Mr. Staplee Firth defended.

Two police officers stated that over a measured distance of 220 yards they timed the defendant's car and found it to be going at the rate 28 miles an hour. The policemen did not stand at the end of the 'track," but some 20 yards further down, and Mr. Firth argued that under such circumstances a correct record could not have been registered.

The defence raised by Mr. Firth was that the timing was quite inaccurate, and that the car, which belonged to Dr. Lawrie, of Harley-street, and was bringing the doctor and a party from Sandown Park races on the day in question, was only going 15 miles an hour.

Mr. Mervyn O'Gorman and Mr. Cozens-Hardy, judges for the Automobile Club, stated that, with Col. Crompton, R.E., they had made a speed test of the car over the same measured eighth of a mile along Kensington Road, and found that the highest speed it attained was 19·7 miles an hour.

CASES DISMISSED.

THE adjourned summons against John Rabling, of Guildford Street, Russel Square, W.C., for driving a motor-car at Surbiton at a greater speed than twenty miles an hour, has been dismissed at Kingston, Rabling, who swore that his speed did not exceed eighteen miles an hour, being given the benefit of the doubt. The chairman added that if the charge had been one of driving to the common danger the defendant would have been heavily fined, as to drive at a speed of eighteen miles an hour on a Sunday afternoon along the Portsmouth road at Surbiton was very dangerous to the public.

AT Hexham Petty Sessions, last week, Dr. J. A. Jackson, of Hexham, was summoned for driving a motor-car on the highway at the parish of Newbrough and failing to stop when signalled to do so by Supt. Appleby. Sup. Appleby, Deputy Chief-Constable of Northumberland, said that on Sunday, March 13th, he was driving a dogcart from Haydon Bridge to Hexham. When a little to the east of Bush Cottages he observed a motor-car approaching. It was emitting vapour freely, and as he had a young mare in the trap, and he was afraid that the animal would be alarmed, he held up his right arm as a signal to the motor-car, which slackened speed. When within sixty or seventy yards of the car he again held up his hand, but the car still came on, and when the mare got opposite to it she swerved, and an accident was just avoided. The car was not stopped as required by section 6, article 4, of the Local Government Board regulations. The defence was that no signal was given, and that the car was slowed down to allow the mare to pass. Dr. Jackson, Dr. Smurthwaite, of Newcastle, and Miss J. A. Jackson, who were also in the car, denied seeing Superintendent Appleby make any signal to stop. The case was dismissed.

BEFORE Mr. M'Connell, K.C., Robert Forsyth, a motor-car driver, was indicted for having, by the wanton driving of a motor-car, caused grievous bodily harm to Mrs. Amy Ryder, wife of a cabdriver living at Park Walk, Chelsea. At the close of the evidence for the prosecution the jury thought that although the matter might be one for a civil court, any negligence of Forsyth was not sufficient to substantiate a criminal charge. They therefore acquitted the accused, and he was at once released.

CONVICTIONS AGAINST MOTORISTS.

Andover	Reckless driving	£5 13s.
,, ...	Travelling above legal limit	£1, etc.
Guildford	No number	10s.
Epsom	Leaving car unattended	6s. 6d.

Brentwood	No light	£3, etc.
Petworth.....	Reckless driving	10s. 6d., etc.
Cheltenham	Reckless driving	£3, etc.

* Licence endorsed in addition to fine imposed.

A POINT FOR DEALERS.

AT the Leeds Police Court, Thomas Walker, jun., was charged with a breach of the Motor Car Act. Mr. Dalton (Deputy Chief Constable) said that on the afternoon of Sunday, March 20th, the defendant was seen driving a motor-car in Great George Street. The car bore the general manufacturer's identification mark—"U.M. 14"—but Mr. Dalton explained, this mark could only be used under two conditions—conditions which applied to new cars for trial after completion, or cars on trial by intending purchasers. This particular car was not being used under either of the conditions, and was therefore unregistered. This was the first case in Leeds under the new Act. The maximum penalty for a first offence is £20, but the Bench imposed in this case a fine of £2, including costs.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to THE EDITORIAL DEPARTMENT, MOTOR-CAR JOURNAL, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, APRIL 30, 1904. [No. 269.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

THE Motor Volunteer Corps is gaining ground, and during the present visit of the King and Queen to Ireland the members of the corps who are resident in Ireland have been assigned the important and honourable duty of acting as a Guard of Honour and escort to their Majesties, and of conveying their staff. This is the first time the corps also has been given such a distinction, and it is interesting not only as providing a new use for a popular branch of the service, but as evidence of the Royal concern for the future of automobilism.

◆ ◆ ◆

Dashwood Hill.

A REMINDER of the old days on Dashwood Hill, when the Premier lunched *al fresco* while the cars rushed up the hill and down again, comes in the report of the hill-climbing contest just held by the Oxford and District Automobile Club. The police have evidently softened their manner towards motorists in allowing such an event to take place, and we hope they will also recognise that, when proper organisation is maintained, there is nothing so very dreadful in such a competition. The course selected by the Oxford club was from the cross roads at the bottom of the hill to the gate at the top, a distance of 930 yards, with an average gradient of one in eleven. In the most severe portions it is one in eight. There were three classes. In that for cars costing about £250, Mr. Biscoe was first on his 10-h.p. Talbot in 2 min. 47 1-5 secs., and in that for cars costing less than the figure already named, Dr. W. J. Turrell's Eagle runabout made the ascent in 2 min. 10 2-5 secs.

◆ ◆ ◆

West Ham Club.

ALTHOUGH one of the newest, the programme of the West Ham Motor Club for the coming season is the longest we have seen. About eighty runs for Thursdays, Saturdays, and Sundays have been arranged up to and including October 30th. Although this is practically a suburban organisation, it has already attained a large membership and secured the active support of several leading men in the borough. The idea is to foster and encourage skill in the manipulation, care and control of the automobile, and "to arouse a wider interest among persons, already motorists, in the general efficiency of their vehicles." The club has attached itself to the Motor Union, and under the captainship of Mr. G. Davis, with Mr. A. C. Davis as hon. secretary, promises to become a useful factor in the popularisation of motoring in the eastern suburbs.

◆ ◆ ◆

Marine Motoring.

ON Whit Monday, the season on the Norfolk Broads opens with a regatta. This will be held on Oulton Broad, and among the new events will be a competition for motor-boats not exceeding thirty feet overall. The Marine Motor Association rules have been adopted for the contest, and a handsome challenge trophy has been offered by Mr. Maudsley Brooke, which will be known as "the Brooke trophy," the competition for which will be an annual event. From what we can hear, there is already a good list of entries, and this contest will give a new zest to the opening of the season on the Broads.

◆ ◆ ◆

In the Sky.

NOT only is the motor-boat season commencing, but the receipt of the programme of the Aero Club reminds us that great doings are likely to take place in the skies during the coming season. The Committee have arranged for members to make ascents in the new club balloon of 45,000 cubic feet capacity. Opportunities will be given for private ascents with friends at any time. The first meet of the club, which will have its headquarters at the Crystal Palace, will be on Saturday next, May 7th, and a programme of the fixtures for the season can be obtained from Mr. E. O. Pope, secretary, at the club room, 110, Piccadilly, W.

◆ ◆ ◆

Motor May-Day.

THE Motor May-day will, this year, take place on the last day in April, owing to May 1st falling on a Sunday. A parade of motor-vans will assemble this (Saturday) afternoon at 3 o'clock on the Thames Embankment, immediately to the east of Charing Cross Railway Bridge. After being judged, a procession will be formed, which will proceed down Victoria Street and Grosvenor Place to Hyde Park Corner, where it will be disbanded. We understand that close upon 100 vehicles are anticipated, which speaks well for the growth of the motor-van industry since the early days when practically every heavy motor-vehicle could have been got into the Minor Hall at the Motor-Car Exhibition at Islington.

◆ ◆ ◆

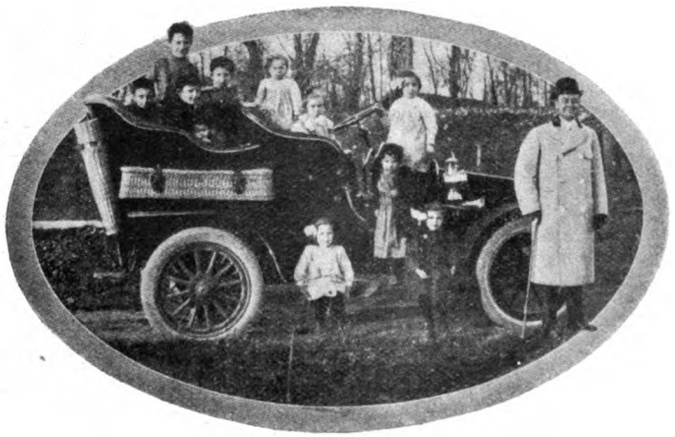
Beyond Experiment.

THERE is no doubt that the commercial aspect of automobilism will have to be even more closely considered than has hitherto been the case. The number of motor-vehicles in use for the transport of goods, the conveyance of produce, and municipal work is increasing every week, to the undoubted advantage of British industry, which leads in this particular branch of the business. Fortunately the firms engaged in the manufacture of these heavy vehicles have been able to study the problem from a practical point of view, with the result that local authorities, as well as the great distributing houses, recognise that heavy motor traffic has got beyond the experimental stage.

◆ ◆ ◆

Educating the Public.

THE idea of an annual demonstration of the advance that has been made is worthy of encouragement by all users of such vehicles. In London a few hundred motor-vans can be scattered about the various suburbs without making any appreciable impression on the minds of the public. But when such vehicles are brought together in parade the importance of the transition now being wrought becomes apparent to the man in the street, and conviction as to the utility of the innovation is



Digitized by Google

hastened. Just as the early meets of the A.C.G.B.I. were useful in familiarising folks with the outline and appearance of automobiles, so will a succession of May day parades do much to popularise the heavier form of motor traffic.

◆ ◆ ◆

13.

THIRTEEN motorists summoned for various alleged offences have appeared at the Haywards Heath Petty Sessions. In court was a display of the methods and the men by whom they were captured. The electrical apparatus used by the police was produced, fully explained, and worked upon the solicitors' table. The police operating the apparatus were Sergeant Suter, P.C.'s Waghorn, Huntley, and Rummery. Mr. Lawson

Mr. John Farson, the President of the Chicago Automobile Club, believes in educating the American youth to the joys of motoring. The above illustration shows a party of youngsters on their return from a ride in Mr. Farson's Winton car.

Lewis appeared in support of the summonses, and Major Lang, Chief Constable, was in court—an array of force showing how determined the police were to secure verdicts. Their solicitor commenced by saying that proceedings had not been taken unless the motor-cars had exceeded a speed of twenty-five miles an hour, and in measuring the furlong several yards had been thrown in, so that it could not be said there was a possibility of mistake. Three licenses were endorsed and not a motorist escaped penalty.

◆ ◆ ◆

Birmingham and Motor-'buses.

A CORRESPONDENCE eulogising motor 'buses as against tramcars has broken out in the Birmingham newspapers, and should be useful in pointing out the merits of the automobile to the local authorities of other Midland towns. Everywhere it is being recognised that the old-fashioned 'bus must go, that the motor vehicle has more adaptability, occupies less space, secures greater speed, and is, in every way, an advantage. Under these circumstances, and having regard to the connection of the Midlands with the motor-car industry, we look to makers of cars to assist those who are now doing something to popularise the motor-'bus with the public.

◆ ◆ ◆

Up Porlock Hill.

APROPOS our paragraph concerning the famous Porlock Hill, it may prove useful to our readers to know that there are two methods of performing the ascent. One is, of course, by the old road, the other by the comparatively unknown new road. In the former instance, the condition of the ground makes the ascent a somewhat fearsome task. The new road, which is only open on payment of a toll, offers a stiff but gradual climb from the level to the inclined plane. The going is, however, fairly good. It is a glorious climb, the road, perilously narrow, following a zig-zag path amidst scenery which reminds one of Switzerland. The view of the Bristol Channel and the run across Exmoor are superb. Mr. Louis Vincent accomplished the journey on a 10-h.p. Lanchester in the company of Mr. Gilbert Fabian and Mr. A. H. Vincent, in the course of a tour in Devon and Cornwall, without a hitch. The Automobile Club might with wisdom follow the example of the C.T.C. in the way of guide posts, as in the case of the Porlock Hill the existence of the new road is only known to a few, and Mr. Vincent informs us he learned of it through the courtesy of a member of the Devon and Exmoor Staghounds. Should this paragraph meet the eye of any of the members of the "Hunt," they might accept his apologies for the stampede which his presence caused among the animals, and which is thus conveyed through our columns.

◆ ◆ ◆

A Census of Cars.

A PARLIAMENTARY return will shortly be issued showing the number of motor-cars (distinguishing motor-cycles from other cars) registered by each registering authority in the United Kingdom under the Motor-car Act of 1903 up to the first of April, and the number of licences under the Act granted to drivers under the same Act, distinguishing between cycles and other motors. Since we gave a complete return of the first month's registration, no effort has been made to keep a tally of the automobiles in use, and the figures that have lately been published are mere matters of conjecture. Some interest therefore attaches to the new return, the issue of which will be awaited with considerable curiosity.

◆ ◆ ◆

A 2,000 Mile Run.

ON Saturday midnight Mr. Cecil Edge started on a two-thousand mile run on a 15-h.p. Napier. The ride is undertaken to specifically try under severe conditions the new synchronised Napier ignition, the new Napier carburettor, and the new system of building up cylinders with copper jackets

The Napier starting on its 2, 00-mile run.

formed by an electrical process. Mr. Edge will be relieved at the wheel from time to time by Mr. F. G. Cundy, but both of them will remain on the car throughout the journey, which will consist of a run from the Automobile Club, Piccadilly, *via* Land's End and John o' Groat's back to Brighton, and then to the Automobile Club. It is in no sense a speed competition, but purely one to test various parts of the motor-car in a way that will, if it is possible to make them fail, do so. They will run without attention from start to finish.

Digitized by Google

Discretion Wanted.

THE police will have to temper justice with discretion, or they may ultimately find themselves in difficulties. The other day a constable in the East End, in the officious discharge of his duty, watched the driver of a motor-van go into a house of refreshment. There was no extraordinary delay, but, filled with enthusiasm for his calling, he determined on a charge. Fortunately the driver had taken every precaution against the motor being started, so that the scheme of Sir Robert availeth nothing. As will be seen from the report elsewhere, the case was rightly dismissed.

◆ ◆ ◆

Lady St. Lawrence.

AMONG lady drivers of motor-cars is Lady Geraldine St. Lawrence, whose photograph we have pleasure in reproducing herewith. On her 12-h.p. Darracq she has travelled over 5,000 miles since February of last year, touring about Bournemouth, Eastbourne, and the south coast, as well as through Kent and Hertfordshire. From her place at Windsor she generally comes to London by motor-car, rarely indeed falling back on the train, which she regards as a somewhat primitive form of locomotion. The present car is her ladyship's second automobile, and she has rapidly developed into one of the most enthusiastic of lady motorists.

Lady Geraldine St. Lawrence on her Darracq Car.

◆ ◆ ◆

Motor-car Literature.

ALREADY the number of books devoted to the automobile has assumed fairly formidable proportions, and of the making of these there is apparently no end. The third edition of Messrs. Lewis and Porter's "Law Relating to Motor-Cars," published by Messrs. Butterworth and Company, has just reached us. As we hinted on the publication of the first edition of this handy volume, it gives a lucid idea of the state of the law with regard to the motor-car. Not only are the Acts of 1896 and 1903 given, but the regulations of the Local Government Board are also included in the volume, which has a useful index. In view of the many cases which have been before the courts during the last few weeks, the work is one which should become quickly popular among motorists.

No Costs to the Police.

AT length Mr. Lane, K.C., has concluded the hearing of the case against a motor-car driver which Mr. Staplee Firth has stoutly defended on three or four occasions. Two police-constables swore that, standing twenty yards below the end of a measured distance of two hundred and twenty yards, they timed the car with stop watches and found it was going at the rate of twenty-eight miles an hour. Mr. Firth, for the defence, called witnesses to prove that according to their opinion the car was not travelling more than fifteen miles an hour. Moreover, an expert test of the capabilities of the car was made by Colonel Crompton, R.E., Mr. Cozens-Hardy, and Mr. O'Gorman, and they stated that the highest speed attainable was nineteen miles an hour. The magistrate, in giving his decision on Monday, remarked that the circumstances in which the police had to conduct such trials must involve a very considerable margin for error. He was bound to say he agreed with a remark dropped by Mr. Firth, to the effect that such methods pursued by the police must give rise to great embarrassment. He thought the weight of evidence, however, in this case rested with the police, and he therefore convicted. A fine of £3 was imposed, his worship refusing to grant costs to the police.

◆ ◆ ◆

Useful Defences.

ALTHOUGH the police secured a verdict they did not gain their costs—a poor sort of victory, in which their position was most unpleasant throughout. Motorists who take a bold stand against the police in such cases have to waste much time and sacrifice more than the public knows; but they are rendering good service to their fellow automobilists, and are to be congratulated even when they are defeated on such terms as were inflicted in the West London court.

◆ ◆ ◆

Duty Free Alcohol.

THE Society of Chemical Industry met recently in Burlington House, London, to hear a paper by Mr. Thomas Tyrer, a past president, on the need of duty-free alcohol for industrial purposes. There is an over-production of spirit from grain for whisky, and owing to the surplus supply

Digitized by Google

some Scotch distilleries have had to shut down. This surplus, it is contended, could be advantageously used by our manufacturers, if the Government would grant a similar privilege to that extended by the German Government to the manufacturers in the Fatherland and free spirit from duty for industrial purposes. A movement is growing in America to remove excise restrictions, so that the makers of commercial articles can compete with the other nations, and it is claimed by English chemists that the removal of existing restrictions on raw material and surplus spirit would be of great advantage to our national commerce.

◆ ◆ ◆

A Fenland Compromise.

MOTOR-CAR drivers are not likely, after all, to be excluded from the main road from Spalding to Crowland after dark. As this runs along a bank, it was considered that the driving of motor-cars at night would be a highly dangerous proceeding, and it was proposed to prohibit the motor traffic. With certain restrictions, however, as to lights—one being placed at each end of the road, and one in the middle, so that they shall illuminate the notice boards—and a speed limit of ten miles an hour, the special committee of the Holland County Council now recommend to the Local Government Board that the road in question shall be open to motorists as to other vehicles. This is a compromise which should be fairly satisfactory to all parties; for, although local drivers might object to the closing of such roads, they are certainly somewhat dangerous to strangers unaware of the proximity of the drains that still exist in the Fens.

◆ ◆ ◆

In the Park.

IN the House of Commons Mr. Bull has asked Lord Balcarres whether he was aware that in some of the roads in Hyde Park motor-cars were not allowed, but that such roads were only indicated by a regulation in small type on a general notice board, and whether, to avoid constant mistakes by motorists coming for the first time to the park, he would cause conspicuous notice boards to be placed at each end of these prohibited roads stating clearly that motors were not allowed. The First Commissioner of Works has made inquiry, and, according to Lord Balcarres, he regrets that he cannot agree that the present arrangement is unsatisfactory. There are constables on duty at either end of the prohibited road. They have experienced no difficulty, and are much more efficient as a warning to motorists than any notice board. Such, at least, was the official view.

◆ ◆ ◆

The Eliminating Trial.

INTEREST in the Eliminating Race to decide the British team for the Gordon Bennett contest is being intensified as the day draws near. The following is the order of the competitors' positions in the race to be held in the Isle of Man on May 10th:—Mr. Stocks, Napier; M. Edmond, Darracq; Mr. Hargreaves, Napier; M. Hemery, Darracq; Mr. Earp, Napier; Mr. Muir, Wolseley; Mr. Edge, Napier; Mr. Girling, Wolseley; Mr. Rawlinson, Darracq; Mr. Jarrott, Wolseley; and Lieut.-Col. Mayhew, Napier. On Wednesday five hundred yeomen were sworn in by the Manx magistrates, to police the roads for the Gordon Bennett Eliminating Trials in the Isle of Man. They took the oaths of allegiance to the King and the Governor of the Island. On Thursday next the Governor of the Island, the Council, and the members of the House of Keys will go in motor-cars for the historic ceremony of promulgating the motor-car law on Tynwald Hill.

◆ ◆ ◆

In Norway.

MR. AND MRS. C. J. GLIDDEN, of Boston, U.S.A., who are now in London, have visited four thousand cities, towns, and settlements on his automobile. Apparently his most serious troubles have been in the north of Europe. The serious restrictions which were sought to be imposed in Norway prohibited anything like motor-car touring in the country. One was that they must send a man ahead on horseback to say that they were thinking of approaching a certain place. Another was that notification should be sent to the sheriff of each place of the exact time when they would pass through. Then they were expected to publish in the newspapers several weeks in advance the route of the proposed journey. There were other foolish regulations too numerous to mention. Mr. Glidden was turned off and drove through Sweden instead. There they had four in the car, having taken an interpreter on board. North of Stockholm, for a thousand miles, the people had never seen a motor-car before. Mr. Glidden was the first person who had ever crossed the Arctic Circle in one. The Norwegians will be sorry for their opposition to the automobile sooner or later.

◆ ◆ ◆

Blackheath Club.

THE Blackheath Automobile Club was formed at a meeting held on Wednesday. The following were appointed to the committee: Dr. J. Strickland Goodall, Messrs. L. Beadle, H. Cunis, A. Duckham, L. C. Lambert, H. Norfolk and S. Norfolk; treasurer, Mr. W. O. Bedford, R.N.; hon. sec., Mr. A. Roberts, Madgelands, Beaconsfield Road, Blackheath, S.E. The inaugural run will take place to-day (Saturday). Local motorists will assemble at 2 o'clock in Beaconsfield Road, Blackheath, round the small Green, opposite Ingleside Grove, where they will be marshalled. The cars will then proceed to Crown Point, Seal Chart, near Sevenoaks, by any route at drivers' option. Tea will be taken at the Sir Jeffery Amherst Hotel at 5 o'clock, the return being commenced at 6.30 o'clock p.m.

◆ ◆ ◆

Australian Advance.

THE first motor-car to travel the Bega district of New South Wales caused a mild sensation. Mr. Levy, representing Messrs. Hoffnung and Company, of Sydney, has travelled in this car through the Milton district. Then from Nelligen up the Nelligen mountain on to the tableland, making from Braidwood to Cooma, and through Monaro, and down the Big Jack Mountain, which is considered the steepest grade in the southern district. Hills and mountains were negotiated quite comfortably, and this is an important step towards dispelling the idea that motor-cars could not traverse the hilly roads in the Coast district. The question of providing a motor-car to convey the mails between Cooma and Bega is now being considered by the Federal postal authorities, consequent upon the agitation of the Bega Vigilance Association, and the recommendation of the New South Wales Railway Commissioners, who suggested a motor-car service some time ago to accelerate the mail service to Bega, which would mean a saving of twenty-four hours between Bega and Sydney.

A MOTOR-CAR service from Ballater to Balmoral, *via* the Bridge of Gairn, Abergeldie, Crathie, Inver, and Bridge of Dee, is being started.

AS we go to press we learn that there is a probability of another alteration in the course for the French Gordon Bennett eliminating contest.

A GOLD medal for motoring and sporting clothing has been awarded to Messrs. Alfred Dunhill, Limited, at the Crystal Palace International Dress, Clothing and Textile Exhibition.

SNAPPING of a chain and punctures delayed Mr. Cecil Edge in reaching Inverness, but repairs were effected without stopping the engine. On Wednesday afternoon he passed south through Carlisle on his way to London, where he was due early on Thursday morning.

DURING the period from March 23 to April 20 the London Council registered 261 motor-cars and 294 motor-cycles, making the total number of cars and cycles registered in London 2,914 and 2,063 respectively. The total number of licences and general identification marks issued is 7,195 and 247 respectively.

THE SIDE-SLIP TRIALS.

WITH THE COMPETITORS ON MONDAY.

MONDAY morning broke fine and bright, about as unpropitious for side-slip trials as could well be, had it not been for the occasional efforts of district authorities to provide a suitable surface with the aid of water-carts. But neither competitors nor Observers objected, and our contentment was great when the ever urbane technical secretary indicated the luxurious Roi des Belges tonneau of a fine 15-h.p. Panhard as our abiding-place for the day. Its tyres and non-skidders looked sensible, and the driver correctly, as it turned out, expected no trouble from them. But we cannot help a suspicion that he was aware that, in default of the ubiquity of Sir Boyle Roche's bird, a car that completes its journey rapidly and uneventfully is not the best place from which to see the incidents of a trial, and a whisper connecting our vehicle with "two o'clock on Sunday morning," from some who had been on last week's runs was somewhat disturbing.

Few participants seemed to have a much better idea of time than a Surrey policeman, and it was long after ten before most of the cars had started, these including a 10-h.p. Georges Richard with the L'Empereur link covers, the Billet, the Parsons, the Wilkinson, and the Vivian, whose driver, we were glad to hear, was able to take part in the run in spite of his bad spill on Saturday. There were also the mechanical devices, the Sainsbury, showing some wear on the cover from the forked blades, the Nicholson, somewhat similar in principle but retractible at will, and not touching the tyre, and the two devices which depend on trailing metal discs; also a posse of motor-bicycles, the riders of which, with their observers on cars, seemed to have a good deal of mutual anxiety.

Shortly before eleven we got off, and made good running through the traffic, several sudden stops on wet tramlines demonstrating the advantage of roughed tyres, and after passing the Nicholson 12-h.p. Star running steadily, and the Parsons stopped by the roadside, at half-past eleven, we began to indulge in hopes of getting back to the club to lunch.

Alas! it was not to be. At Colnbrook we overtook a long procession of carts, in close order, and when half way along perceived a cart entering the narrow passage left at the other end, fifty yards ahead. Stopping immediately, we expected it to do the same, but the carter, who seemed to have been making experiments prompted by Dr. Ormandy's recent paper, whipped up and tried to pass by driving on the path, colliding with our off Bleriot, which was not strong enough to stand the strain, and driving our car twelve feet back. One of the spectators proved to be the local police superintendent, who after much difficulty succeeded in eliciting the carter's name, which, with the subsequent formalities, detained us some time.

Ten minutes after starting further trouble began—the pump leather was nearly gone, and before reaching Slough had quite disappeared. Fifty minutes in that interesting old town, while a bootmaker repaired damages; meanwhile the cars we had passed went by with looks of complacent sympathy. Finally we got on the move again, but not for long; at the Yew Tree Inn, on the Slough-Beaconsfield road, the engine went on strike, and a steep hill intervening between that place and Beaconsfield, there was nothing for it but another overhaul, which revealed valves entirely gummed up, the result of lubricating them with oil. When the eight had been attended to (possibly six and eight-cylinder engines may have their drawbacks) we got off again, a Wolseley and the "Billet"-tyred car with its bicycle having passed us in the interim, as well as the big motor omnibus which plies on that road, whose offers of assistance we politely refused. We were now going, though feebly, just managing to surmount the danger-boarded hill; but matters improved a little, and, with another short stop or two, we got home without a breach of the law. Here we found the Billet, reporting little except the breakage of one securing wire, and the loss of its attendant bicycle, which we were unable to give news of, and having business which did not allow of a possible midnight return, turned over the car to another Observer for the second round, and waited for the further arrivals at the garage. The first proved to be the Georges Richard, with L'Empereur covers, which had done its two rounds without a hitch, at a good legal average, while a little later the Benz-Parsifal with Vivian treads turned up, but it was only its first lap. The driver, however, was unequal to another round, as we heard, after his accident last week, and had to retire. Further waiting brought no news for some time, and we left with the fate of those on the road still undecided.

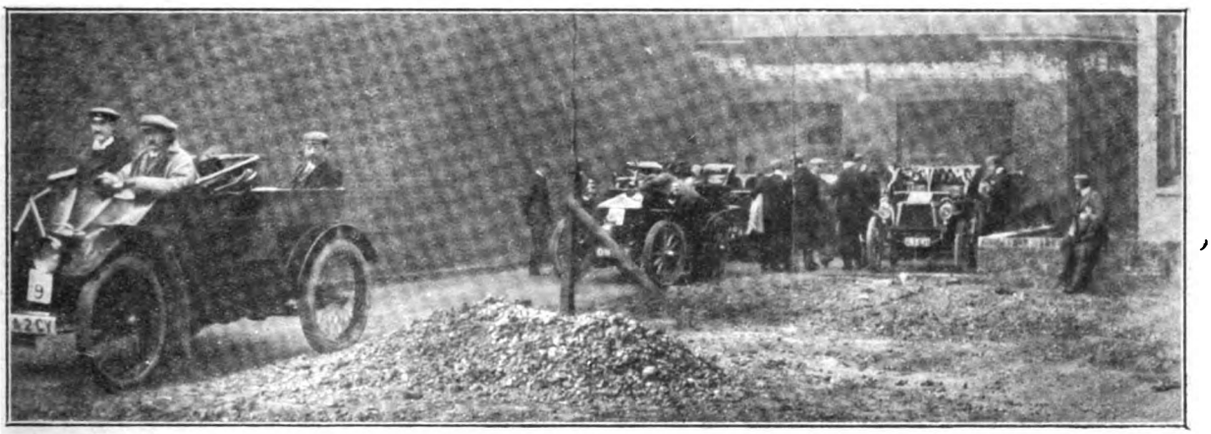

Photo by The Cars leaving the "Locomobile" Garage. [*Mr. A. E. Perman*

◆ ◆ ◆

MR. W. MAITLAND EDWARDS withdrew from the Side-Slip Trials because his own car broke down at the last moment. Mr. Eadie very kindly lent him a Royal Enfield car, which went through the trials admirably, but the tyres were smaller than the tyres for which Mr. Edwards had made his non-skids, so that he had to hurriedly rush through a pair of other covers to fit these smaller tyres in about three hours. The result was that they were so imperfectly constructed that they would not stand the wear and tear on the road that they were required to do. Thus it will be seen that the reason of withdrawal was simply faults caused by hurried construction, and had nothing to do with the design. Owing to there not being time to make another pair of covers with which to complete the road journeys, the Edwards is not available for the actual side-slip contests.

◆ ◆ ◆

THE Midland A.C. entertained the officials connected with the A.C.G.B.I. side-slip competition to a dinner at the Grand Hotel, Birmingham, on Thursday of last week. A large party were present, including the president of the club—J. Broughton Dugdale—Sir J. H. Macdonald, W. Ballin Hinde, Alfred Bird, J. Holder, Rees Jefferies, Basil Joy, T. C. Aveling (hon. sec.), E. A. Stephens, C. P. Type, Hamilton Barnsley, Dr. Wingfield,

Digitized by Google

Major Lindsay Lloyd, H. Luff-Smith, A. Johnson, Pinsent, Lawrence and E. C. Lord. Dinner over, an adjournment was made to the motor garage to inspect the various non-slip devices. Ample assistance was given by the club members in piloting the competing cars through the Birmingham streets, and additional services were rendered by Mr. E. A. Stephens, the following day, in carrying members of the Press and also piloting the car through Coventry *en route* for Nottingham. The Wolseley Co. also sent a special car over to Coventry for this purpose.

THE hill-climbing contest of the Herefordshire Automobile Club has been postponed from the 3rd to the 10th May, the day of the Gordon Bennett race.

WE learn that a public service of motor-cars is to be inaugurated early next month between Wimbledon station and the Polytechnic estate. A 15 minutes' service will be maintained in both directions.

WHILE a motor engine was proceeding to a fire at Liverpool, the wheels skidded on the tram lines, causing it to swerve violently against an electric standard. Several firemen were thrown off and badly injured, while the motor was partially wrecked.

THE COST OF OPERATION.

ACCORDING to a popular idea motor-cars are an expensive luxury—"the toys of the rich." The great attention which is now being paid to cars for "men of moderate means" has, however, done much to remove this impression, and with the rapidly growing number of vehicles available at a popular price, queries as to the cost of running and maintaining the same are frequently being received. The cost of keeping a motor-car may be divided up into several factors, as follows: Cost of operation, maintenance and depreciation. A complete account of the cost would, of course, also include interest on investment. It is this combined cost of operation, maintenance, etc., that especially interests the user and prospective owner. Any one of the separate items is of little value, especially the item of operating cost, which is always small as compared with the figures of maintenance and depreciation.

It is, of course, too early for much information on this subject to be available, as to figure the average cost per mile during the life of a vehicle the latter must be run till it is completely worn out, or at least so far run out that its further use is commercially impracticable. Few vehicles have reached this state, and those that have are to-day out of date, and it would be unfair to draw conclusions as to the cost of keeping an up-to-date vehicle from the cost of keeping these.

Photo by] The Side-Slip Trials.—The Motor-Cars and Cycles Preparing to Start on Thursday of last week. *[Argent Archer.*

ANOTHER motor-car trip from San Francisco to New York is to be attempted during the coming summer. The run is to be undertaken by Mr. B. Holcomb, who will drive a 30-35-h.p. Columbia petrol car built by the Electric Vehicle Company, Hartford, Conn.

THE other day we had an opportunity of going over the large and well-equipped motor repair works which have lately been established in Croxted Road, Herne Hill, S.E., by Messrs. F. Garner and Company. Not only has plant been installed for the repair of all kinds of cars but a motor-body building department has been added, while storage accommodation is available for about twenty cars. Needless to add, a supply of petrol, motor oils and accessories is kept on hand.

MR. ANDRE A. GODIN, the British agent for the Dinin ignition accumulators, has just issued two useful pamphlets relating to these batteries; one refers to accumulators filled with acid for motor-cars, and the other to batteries filled with solidified electrolyte for use on motor-cycles. The booklets have been specially prepared to give all information to motorists who use these batteries. They give full details respecting the treatment and charging of accumulators as well as many useful hints of a general nature. Users of Dinin accumulators would do well to obtain a copy of the pamphlets, which will be furnished gratis.

A factor of great influence upon the expense will always be the care of the owner. In this connection we would, states the "Horseless Age," quote M. Michelin, the tyre manufacturer, who states that 60 per cent. of the tyres returned to his factory for repairs or to be exchanged have been injured solely through the carelessness of the drivers. Excessive speeds are most trying to all parts of the mechanism—a fortunate condition in one respect, as it is bound to put a check to the speed craze. The careful owner who avoids excessive speeds, the ruts and obstructions of the roads, and who forestalls as much as possible all accidents by proper attention to the lubrication and regular inspection of all parts subject to wear or liable to come loose through the vibration, will, in all probability, succeed in running his car at a much smaller cost and with more general satisfaction than one who does not take these precautions.

We have given accounts of the cost of operating cars in several previous numbers. As this factor is dependent upon so many variable conditions, it is, of course, desirable to have the experience of many users, aud we take this opportunity of stating that we are always glad to receive communications bearing on this subject for publication in the *Journal*.

THE OPENING MEET OF THE SCOTTISH AUTOMOBILE CLUB.

[By Our Special Correspondent].

A SARCASTIC Southerner once remarked "Glasgow was a first-rate place to get out of," and if there was a sly hit at its grey streets and many chimneys, it is very true from the point of view of the ease with which its citizens can readily transport themselves by road, rail, or river to the most beautiful and romantic parts of the country. This never came home to me more vividly than on Saturday last, when in quest of the owner of a fast car with whom I was to attend the opening meet of the Scottish Automobile Club at Callender.

Leaving Glasgow early in the forenoon, we had a capital run north, *via* Cambernauld and Denny, and past the famous field of Bannockburn into Stirling. The day was dry and clear, and as we approached Stirling the scene was very fine—the Castle Rock and Wallace Tower in front, while the clear outline of the Ochils stretched to the right and the snow-clad peaks of the nearer Grampians were conspicuous to the north and west. We sped gaily right through the busy county town, up the banks of the Forth, and along one of the best motoring roads in the country, straight, level and wide for several miles, into Doune. We smiled as we remembered an incident that happened here on a fishing excursion with a friend on one occasion. He had toiled all day and had still an empty basket when a man hailed him, and, after inquiring as to his success, shared a full basket of fine trout. Our companion at the inn door later in the evening pointed out the man to "mine host" as the keeper who gave him the fish, and was aghast when told that his benefactor, whom he had tipped with half-a-crown, was a peer of the realm and a large local proprietor. We could fancy the mirth at his lordship's dinner table that evening.

A pleasant run on the switchback road along the Teith brought us to Callander in good time for lunch, and at the Dreadnought Hotel I found we had been anticipated by many cars. Many well-known motorists were to be seen. Mr. Adams, the chairman of the Western Section, was just getting out his Wolseley, Mr. R. J. Smith, the honorary secretary, Mr. John Ross, Councillor McFarlane, Edinburgh, Mr. Hugh Reid, Mr. Lobnitz, and Mr. Holms Kerr being among the well-known figures, and we noticed the Compte Louis de Clerq, wearing the badge of the French Club, on a pure white Gillet-Forest car. It was quite a representative gathering, comprising about fifty cars, and as they all were well laden, well nigh 200 ladies and gentlemen.

After lunch we spent a pleasant hour talking petrol with friends and examining the vehicles. There was a wide range—Panhards, Daimlers, De Dietrich, Darracqs, Wolseleys, Napiers, Humbers, Talbots, Peugeots, and, as is to be expected among over a score different makes, a goodly show of Glasgow Argylls, Albions, and Arrol-Johnstons, as well as one—to us—new Glasgow car, the St. Vincent.

The advent of so many vehicles created quite a stir in the little tourist resort, and a number of the visitors, of whom there are few at present, inspected them during the afternoon. Callander is an ideal place for a meet. It is central and is accessible from both Glasgow and Edinburgh, both of which cities were well represented on Saturday, is at the gateway of the Highlands, and the rugged grandeur of the surrounding Bens give an impression of solitude and majesty which is difficult to reconcile with a breakfast near Glasgow Bridge two or three hours before.

Some of the party left early, to go further north and return to the city of St. Mungo by Glen Ogle, Glen Falloch and Loch Lomond. We took the hill road to Thornhill to Aberfoyle and found there again quite a small motor meet, many having elected to visit the Clachan for tea, and there, in the Bailie Nicol Jarvie Hotel, the experiences of the day were discussed. There was really not much to discuss. The days of breakdowns are over. On Saturday we scarce heard of a tyre trouble, and let me here say this that was not the fault of certain of the road authorities. For five miles we drove over certainly a bye-road, new metal patches, and up one place we had to go right through a stretch like an open quarry. If these are the County Councils, who have received no encouragement from Mr. Graham Murray for their restrictive proposals, coals of fire for automobilists could be better represented than by undressed macadam.

My host landed me safely at my door just as darkness set in, and I was able before leaving him to congratulate the Club on the success of their opening meeting, and to drop a hint that I would not object to be a regular guest. The policy of the Club in arranging their runs to such and to so many parts of the country must have much value in accustoming the rural population to motor traction, and have a powerfully educative influence generally.

A Trio of Motoring Doctors—Dr. Du Beauvais, Dr. Sharp and Dr. Gilpin—at the Meet of the Lincolnshire Automobile Club at Grantham.

AT a meeting of the Derbyshire County Council, the Highways Committee reported that consideration had been given to the provisions of the Motor Car Act, 1903. Returns had been obtained from various local authorities, from which it appeared that the number of posts required for the county under section 10 of the Act was about 2,000, and the probable cost of erecting such posts would vary from 10s. to 20s. each. The Committee recommended that no action be taken with regard to the posts for at least one year.

THE HIGH-TENSION IGNITION SYSTEM FOR PETROL MOTOR-CARS.

By J. W. Frings.

(*Continued from page* 178).

ACCUMULATORS.—On the other hand, accumulators with careful use, improve with each successive charge and discharge, and may reasonably be expected to give some years' constant service. The internal resistance of an accumulator being extremely low—practically nil, in fact—it is very necessary that great caution should be used to avoid short-circuiting it, *i.e.*, the resistance of the coil should always be included in the external part of the circuit for the current to traverse. All accumulators, as was inferred under "Ampere," are constructed to charge and discharge at a certain rate. A certain number of hours is necessary to permit the chemical reactions in the paste to be effected without danger of damage to the grids, or plates, and if these changes are hurried, either in charging or discharging, beyond a certain limit, the rapidity of the reactions forces the paste out of the grids and the latter buckle and bend under the stress. The voltage of the accumulator, as well as its discharge rate, is more constant than that of the dry battery, so that whenever a convenient means, at a reasonable cost, of recharging exists the accumulator is to be preferred. An accumulator which consists of two separate cells connected in series should show a voltage of about 4·4 when fully charged, its ampereage capacity depending, of course, on the size of the plates. As the charge is withdrawn from the battery the voltage falls, but not in proportion, as will be shown. Assuming the charge to be thirty ampere-hours, it will be found that one half that charge may be withdrawn with only a fractional fall in voltage, say to 4 volts, but after that point has been passed the fall in voltage is far more rapid, till it drops to 3·8 or 3·5, at which figure the battery may be considered to have been discharged as far as is advisable. Many authorities contend that it is best to withdraw no more than 25 per cent. of the total charge from the cells before recharging, but with care 75 per cent. of the charge may be withdrawn if the cells be recharged immediately. If it is desired to leave accumulators out of work for some considerable time, they should be fully charged before being put aside, and it is desirable, in any case, to give a small recharge, whether working them or not, at intervals not greater than a month. There is a constant tendency on the part of the cells to discharge themselves automatically, and when this is not neutralised, by recharging, sulphating of the plates—an inimical reaction of the paste—occurs, which interferes seriously with the capacity of the cells until remedied by continued charging at a low rate. The normal discharge rate through a well-constructed coil, which, by its resistance, reduces the discharge, will be about half an ampere, so that if a battery of 40 ampere-hours capacity be used with this discharge rate, and one half or rather more of the total charge be withdrawn, the accumulator will work the ignition system, with continuous discharge, for 40 hours or more. But as there are intermissions—breaks in the continuity of the current supplied for ignition purposes—probably nearly double this number of hours' work could be obtained. In the construction of the accumulators it is necessary to have spaces between the plates for the electrolyte to function as one of the elements of the cell, and herein lies the possibility of short-circuiting internally, by undue vibration as well as excessive discharging. When the paste, which, in forming the cells, is forced into perforations in the lead grids under great mechanical pressure, drops to the bottom of the cells or lodges between the plates, it forms a bridge for the passage of the current and destructive discharge. In justice to the makers it must be said that the accumulators as usually made stand wonderfully well the enormous shocks and incessant vibration to which they are subjected on motor-vehicles. Recent advances in construction have been made by "armouring" the plates, *i.e.*, protecting them from the possibility of dropping paste particles, occasioning a short circuit, by sheets of finely perforated celluloid closely attached to the plates, the perforations allowing a free circulation of the electrolyte. The greatest danger of injury, buckling the plates by external short-circuiting, is, however, only partially obviated by this armouring, and the experiment, too frequently made, of endeavouring to ascertain what charge, if any, remains in the battery by connecting the terminals with a stout wire or good conductor should never be indulged in. Neither should an amperemeter—an instrument for measuring current strength—be coupled direct across the terminals of an accumulator, affording as it does a path of practically no resistance, in other words, a short circuit, and allowing the accumulator to discharge itself at many times its correct discharge rate.

The Induction Coil.—This is perhaps the least understood of the various items of the ignition system. Its particular function is to "create," by induction, a high-tension discharge across the gap at the sparking plug. The coil itself consists of at least four important elements, and, in the case of a trembler coil, of an additional one, the vibrator, or trembling contact breaker. The four elements which comprise the coil proper are the iron core, the primary and secondary windings and the condenser. The primary circuit consists of a number of turns of fairly stout insulated wire wound spirally and in superimposed layers around a bobbin within which is placed the core, the latter, when the current is allowed to circulate in the primary, becoming a powerful electromagnet. The passage of a current through a coil of wire creates a magnetic field throughout its immediate vicinity. Such a coil is termed a solenoid, and possesses all the properties of a permanent magnet with the important difference that the magnetism is wholly under control, and ceases entirely when the circuit is opened. The strength of the magnetic field, and consequently of its inductive capacity, is proportional to the number of turns of wire and the ampereage of the current which is flowing. If, whilst the current is circulating in the turns of a solenoid, a mass of iron is introduced within the coil, it is found that the intensity of the magnetic field is increased enormously, this being due to the fact that iron has less magnetic resistance than air, or a greater conductibility for the lines of magnetic force, in the ratio of one to two thousand. If the core be a solid piece of iron, "eddy" currents are produced in its mass, so that it is usual for the core to be constructed of a bundle of soft iron wires, each lightly insulated from the other, and the whole pressed into a cylindrical form. As has been said, the strength of the magnetic field is proportioned to the number of turns and strength of current circulating in the solenoid, so that it is advisable to have as many turns as possible, without opposing too much resistance to the current flow in the primary circuit, the complete path of which embraces the whole of the low-tension wiring—the lightly insulated conductor—and which passes in turn from the battery through the primary windings to, and through, the interrupter and switch and so back to the battery. It is now obvious that whenever the primary circuit is closed an extremely powerful magnetic field is created in its vicinity. Whenever a magnetic field is introduced into a solenoid an induced current of contrary direction is created in that solenoid, and with each make and break in the generating circuit a reversal of direction is given to the induced current in the adjoining solenoid. The potential difference of such induced current is directly proportional to the number of turns and inversely proportional to its proximity to the locality of greatest intensity of the magnetic field. It follows, then, that in order to secure the highest efficiency in the secondary discharge—in which current strength (ampereage) is of no importance compared with difference of potential (voltage)—this result will be best obtained by a great number of turns—many layers of very fine insulated wire wound around the primary coil as closely as efficient insulation of turn from turn, as well as of layer from layer, will permit.

(*To be continued.*)

Mr. Lambert, of S. R. Bailey and Lambert, Limited, has been ordered by his doctor out of England for a few months. In future all business of the firm will be transacted from Pelham Street Garage, South Kensington, W.

GORDON BENNETT RACE NOTES.

THE course for the British Eliminating race has been finally decided. The start will be from the level, at the Quarter Bridge, and the finish will be on the level in front of Mrs. Fuller's house, on the road leading from Bray Hill, past the foot of Brunswick Road, to the Quarter Bridge. The "control" places include Ballasalla, Castletown (from the railway station to the Malew Road), Ramsey (from the Windmill to Mayhill), and the sharp turn at Watterson's (Tromode, near Douglas). By the permission of Mr. Oates, Cronk-ne-berry, several nasty corners have been removed from the course on the approach to Douglas, by the road from Cronk-ne-Mona to Watterson's Tromode. This improvement in the road will be permanent, and makes one of the advantages which all classes of horsed vehicular traffic will derive from the arrangements for the motor races. For the purpose of providing stands to view the race, the Town Council have secured all the fields between the foot of Bray Hill and the Quarter Bridge.

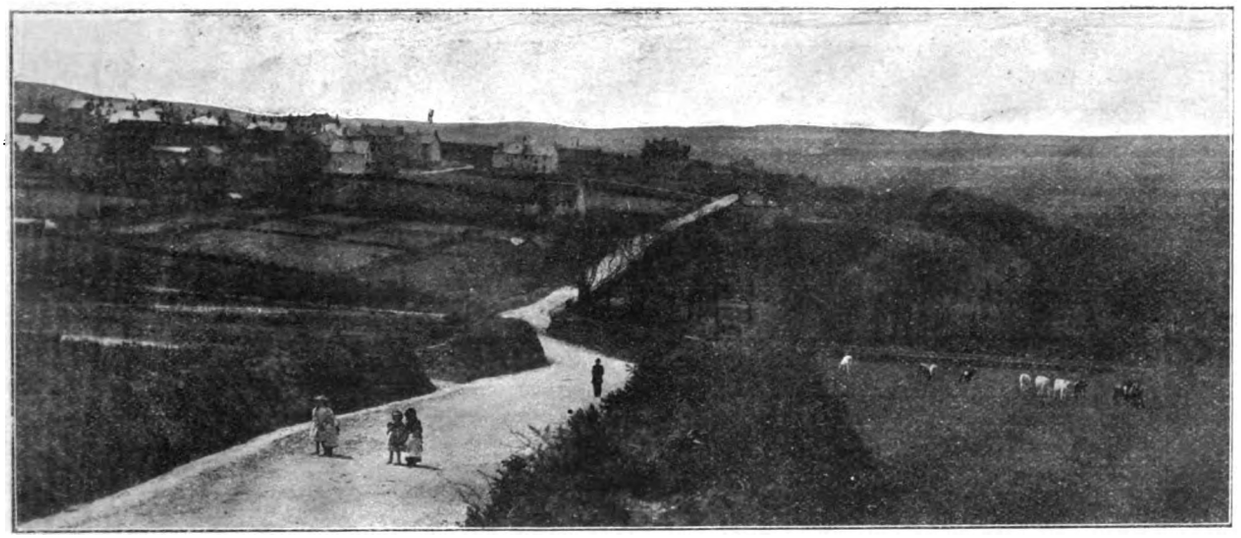
◆ ◆ ◆

THE Mayor of Douglas has declared that all the dates are now positively fixed—the 10th of May for the British eliminating trial over the course already fixed; the 11th of May for the hill climbing contests; and the 12th of May for speed tests. Subject to arrangements for barricading, etc., being made with the Douglas Town Council, the speed tests will be along the Douglas Bay Promenade. The venue for the hill-climbing contest has not been fixed, according to latest advices.

◆ ◆ ◆

MANY persons anxious to have the best view of the races are wondering what point of the course to occupy. Snaefell will certainly be a favourite place, there will be plenty of room and to spare, and, if it be a fine day, Pen-y-Phot will be hard to beat for a comprehensive view. The Keppel Gate will be another good point, and, it should be added, there will be electric cars running to Snaefell at all hours of the day. Mr. J. Cunningham intends to erect near the Bungalow a number of bell tents for parties who desire to spend the night there, to be in readiness for the morning. Mr. R. M. Gardiner, the manager of the Electric Railway Hotels, is making most elaborate arrangements at the Bungalow for providing any number of people with refreshments; so that, next to Douglas, the bulk of the sightseers will probably be in the neighbourhood of Snaefell.

◆ ◆ ◆



THE services of a score of trained ambulance men have been secured. These will be distributed over the course in squads of four each, under the charge of a properly qualified medical man. The ambulance corps is recruited entirely from the Onchan Branch of the St. John Ambulance Society. According to present arrangements there will be five stations on the course, viz., the house of Mrs. Clucas, Spring Valley, near Douglas; the Victoria Road Board School, Castletown; a house adjacent to the Ballacraine Hotel, St. John's; the Municipal Buildings, Ramsey; and the Bungalow, Snaefell Mountain.

Widening the Road and Easing the Curves at Cronk-ne-Berry.

THE ELIMINATING COURSE IN THE ISLE OF MAN.

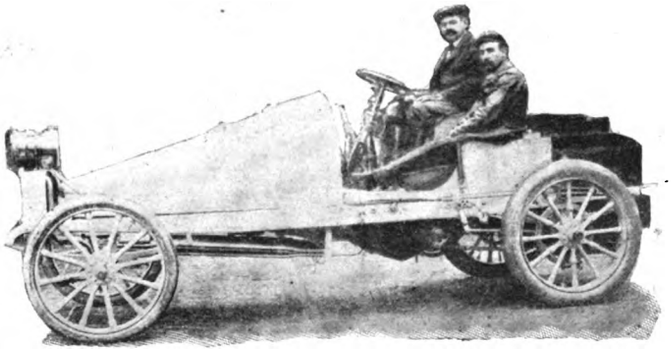
Digitized by Google

THE 1904 Gordon Bennett race is apparently to be well supported by Royalty. In addition to the Kaiser, the Grand Duke of Mecklenburg-Schwerin, the Grand Duchess Anastasia, Prince and Princess Friedrich Leopold of Prussia and Prince-Friedrich Karl Hohenlohe have notified their intention to witness the event.

◆ ◆ ◆

THE Continental-Caoutchouc and Gutta Percha Company are prepared to furnish particulars of the route, hotel accommoda-

M. Clement, junr., on the Clement-Bayard Racer.



tion, and any further information required by English Automobilists going over to the race. An Automobile Guidebook for Germany is being issued by the company.

◆ ◆ ◆

ANOTHER chance is to be given motor-car builders in the United States to be represented in the American team in the Cup race, the racing committee of the A.C.A. having announced that the entry list for the American team has again been thrown open and would remain open until May 1. The reason given for the re-opening of the list is that the withdrawal of the Sampson car left a vacant place in the team. It is understood, however, that the real cause is that the Winton Company desired to make an entry. The old and new entries must be submitted to the committee on May 1st.

◆ ◆ ◆

OF the twenty-nine cars entered for the French team, eighteen will have side chain transmission, viz., Mors, De

M. Pelzer on the Serpollet Racer [*L'Automobile.*

Dietrich, Hotchkiss, Georges Richard-Brasier, Gobron-Brillie, three each, Clement-Bayard one, and Turcat-Mery two; eight cars—Darracq and Panhard three each and Clement-Bayard two, will have cardan shaft transmission, while the three Gardner-Serpollet cars will be driven by a single chain. The latter will have six-cylinder engines. All the petrol cars will have four-cylinder vertical motors.

◆ ◆ ◆

As mentioned above, two of the Clement-Bayard cars will be of the cardan shaft driven type. One of them, with M. Clement, junr., at the wheel, is illustrated herewith. The four-cylinder engine is rated at 80-h.p., the cylinders being 155 mm. bore by 160 mm. stroke. The Clement-Bayard chain-driven racer is a more powerful car, having an engine developing from 100 to 120-h.p. It is not yet completed, and there is a doubt as to whether it will be ready in time.

MOTOR-CYCLING NEWS.

A CUP of the value of £200 has been offered by the Italian sporting journal "Verde e Azzurro" for a motor-bicycle event during the coming season. It will probably be allotted to the Milan-Venice contest in July.

◆ ◆ ◆

PROFESSOR HUGH L. CALLENDAR will read a paper on "The Indicator Diagram of a High Speed Motor" before the members of the Auto-Cycle Club on Wednesday next. The diagrams will be displayed on a screen, and the apparatus by which they are obtained will be shown in use on a motor-cycle.

◆ ◆ ◆

UNDER the auspices of the Motor Cycle Union of Ireland, a hill-climbing competition—the first of the season—took place at Bangor, County Down, on the 16th inst. There were fifteen entries for the event, which was over a 750 yards course. The results were:—McFarran, 2¾-h.p. Bat, 1; Stewart, 3-h.p. Centaur, 2; McStay, 2¾-h.p. Riley, 3. The winner's net time was 42 3-5 sec. A protest was afterwards laid against the winner owing to a discrepancy in his entry form, it being discovered on weighing the competitors that McFarren scaled about 12 lbs. lighter than his entry. He was consequently disqualified, the first place being awarded to Stewart, McStay being second and Vincent third. On Saturday last the members of the Union held a run from Dublin to Portmarnock. The object of the outing, apart from being an official opening to the season, was to test the suitability of the silver strand at Portmarnock for the speed trial which the Union intends to promote during the year.

◆ ◆ ◆

AT a meeting of the Metropolitan District Association of the Cyclists' Touring Club last week, Mr. A. Candler read a paper on the motor-bicycle. The author considered that a novice should be satisfied with a 2-h.p. engine. Fifty pounds would, in his opinion, buy a first-class machine with the necessary extras and accessories. The outlay for a year's riding of 5,000 miles would not exceed £10 for fuel and repairs. The rear tyre should last about 5,000 miles, and the front one nearly double that distance. A very liberal allowance for depreciation added to the out-of-pocket expenses showed that a penny a mile was an outside estimate of the cost of motor-cycling. Experience had showed him that, with regard to touring, it was easy to run a hundred miles a day for a fortnight on end, devoting only twenty minutes to half an hour daily to oiling up and ascertaining that everything was in order.

◆ ◆ ◆

SO far forty-four entries have been received for the twenty-four hours' run to Edinburgh which is being organised by the Motor-Cycling Club. The competitors will meet at the Red Cross Hotel, Paternoster Square, E.C., at 8 p.m., on Friday, May 20th, and must be prepared to move to the starting point (G.P.O.) at 9.45 p.m., where they will be despatched at intervals of thirty seconds. The first will leave at 10 p.m. The order of starting will be in accordance with the receipt of entry. The programme and time table are as follows:—Biggleswade, check by giving up ticket, no need to dismount unless petrol is required. Grantham, control and check, no rider to leave before 3.45 a.m. Arrangements will be made here for early breakfast, and for filling petrol and oil tanks, and also lamps (oil or carbide) at reasonable charges. Tuxford, check by ticket. Wetherby, control and check, no rider to leave before 8 a.m. Durham, control and check, no rider to leave before 11.30 a.m.; lunch will be served here. Alnwick, check by ticket. Berwick-on-Tweed, control and check, no rider to leave before 3.30 p.m. Dunbar, check by ticket, no need to dismount. Levenhall (Musselburgh), control and check, no rider to leave before 7.40 p.m. Finish, North British Hotel, Edinburgh, close to G.P.O.; check. Riders can obtain petrol at the following places: Biggleswade, Grantham, Wetherby, Durham, and Berwick-on-Tweed.

A FULL list of agents for Pratt's motor spirit will be sent to anyone dropping a postcard to the Anglo-American Oil Company, 22, Billiter Street, E.C., the sole importers.

THE "BROOKE" 15-20-H.P. CAR.

ONE of the surprises of the recent Show was the new four-cylinder 15-20-h.p. car exhibited by Messrs. J. W. Brooke and Company, Limited, and illustrated in Fig. 1. The frame is of pressed steel with an internal supplementary frame to carry the engine and one end of the gear box. The secondary frame consists of a light but strong channel section. The engine

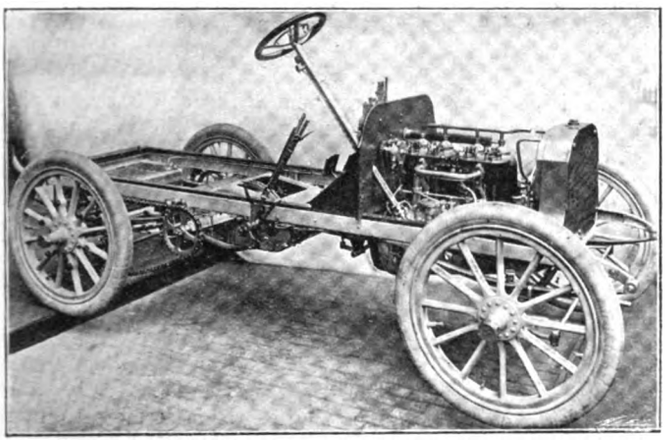

Fig 1.—Chassis of Brooke 15-20 h.p. Car.

is placed longitudinally on this and is supported by four feet, the whole being under a neat bonnet. The front of the latter is filled by a honeycomb radiator, a current of air being drawn through it by a belt-driven adjustable Blackman fan. The front and back ends of the frame both taper to form the spring hangers, the back springs being spread to obviate the rolling motion noticeable in narrowly-hung cars.

A view of the engine showing the inlet valve side is given in Fig. 2, from which it will be seen that the four cylinders are cast in two pairs, the water jacket also surrounding the valves. The latter are all mechanically-operated and interchangeable; they are located on the opposite sides of the cylinders, being driven by separate cam shafts; the induction cam shaft also operates the

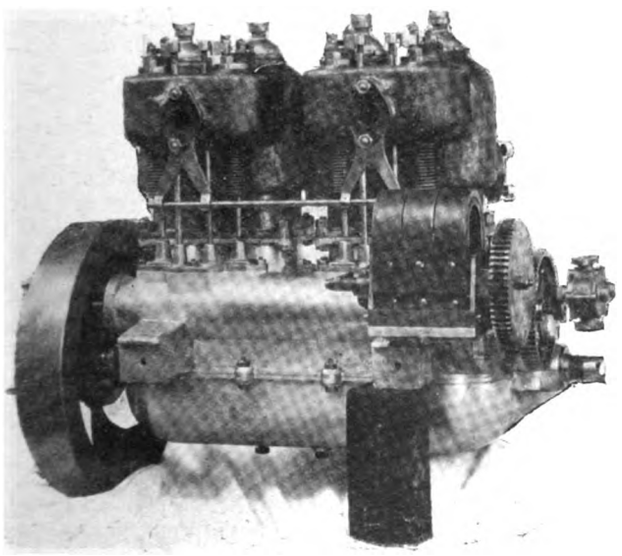

Fig 2.—The Brooke 15-20 h.p. Four-Cylinder Motor.

magneto tappets. The cylinders are 3 5-8 in. bore by 4¾ in. stroke, the normal speed being 900 revolutions per minute. Ignition is by low tension magneto, the magneto machine being driven by fibre wheels on an extension of the induction valve cam shaft; the igniters are placed immediately over the inlet valves and are operated by vertical shafts which obtain a bearing in the main cylinder casting. The ignition advance is obtained by raising or lowering the actuating rod, and as these work inside the crank chamber on discs formed on the cam shaft with steel cam plates securely screwed to them, they are consequently always working in oil. High tension ignition is fitted as an auxiliary; the contact breaker is of the regular "Brooke" type, driven by a chain and placed on the dashboard; the sparking plugs are fitted immediately over the exhaust valves. Each cam shaft has three bearings; the crank shaft has two large end main bearings with an additional bearing between each crank. A gear driven pump is fitted on an extension of the exhaust camshaft and is self-contained with the engine. The inlet for the water is at the bottom of the jackets and the outlets are formed by cones on the highest spot in each cylinder. The flywheel, of large diameter, is bolted to a flange on the end of the crankshaft and contains the internal friction clutch, which when in action gives no end thrust. A fan is formed by the arms of the flywheel to exhaust the hot gases from under the bonnet.

The carburettor used on this car is an automatic one of special design and combined with the Brooke patent governor; a sectional view of it is given in Fig. 3. A. is the float chamber of the standard type, B. being the jet and P. the outlet of the gases to the motor. The hot air enters at F. and the additional air is admitted according to the requirements of the motor by the disc valve D^1, which works in the casting D.; the tension of the spring underneath the valve D^1

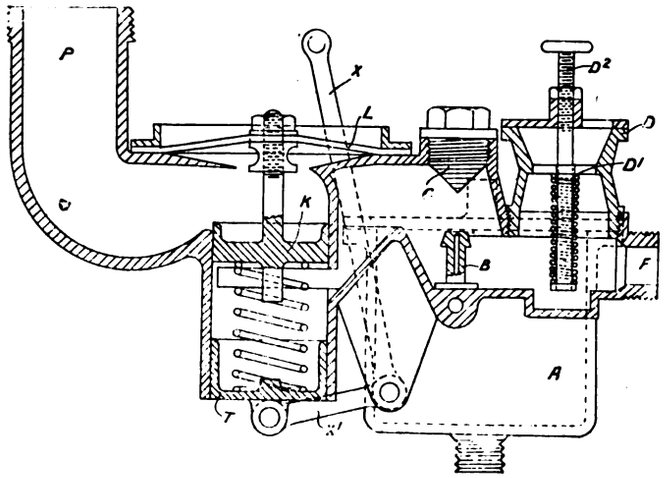

Fig. 3.—Section of Brooke Automatic Carburettor.

is regulated by means of the spindle D^2. This constitutes the carburettor portion of the device; the governing is effected by means of the piston K., the gases passing over the jet and through the slots, and thence through the angular pieces in the piston K. The tension of the spring underneath the latter is regulated by another piston T., which in turn is controlled by the levers X^1 and X. from a rack on the steering wheel, so that the tension of the spring on the piston K. can be regulated as desired, and consequently the speed of the engine governed. L. is a leather diaphragm to which is attached the piston K. by means of a rod cast in one piece with it. At a high rate of speed the engine is creating greater suction than at a low speed, and consequently the passing vacuum caused in the pipe P. has the effect of causing the leather diaphragm and the piston to fall and so close the ports admitting the mixture.

The power is transmitted to the gear box through an internal leather-faced clutch contained within the flywheel. Between the clutch and the gear box is a flexible joint which compensates any want of alignment between the two and permits the clutch to be detached without disturbing the engine or the gear box. The latter is similar in many respects to the gear-box fitted to the standard Brooke cars, but, instead of a chain, a propeller shaft and bevel wheels have been fitted, and the three-point suspension has been adopted. The gear box proper consists of five parts—the top and bottom halves, the two arms to

Digitized by Google

the sprockets and the bevel pinion bearing. The gear box can be dropped right out of the car in less than ten minutes, the only operation necessary being the uncoupling of the propeller shaft and the slackening away of the nuts on the three suspending points. Three speeds forward and one reverse are fitted, all actuated by one lever and operated by a circular cam inside the gear box, a section of which is given in Fig. 4. The forward speeds are all obtained by chains of 1 in. pitch running in thin oil, the desired pair of chain wheels being made to transmit the power by means of claw clutches. The reverse is obtained by means of gear wheels. The system has been in use now about

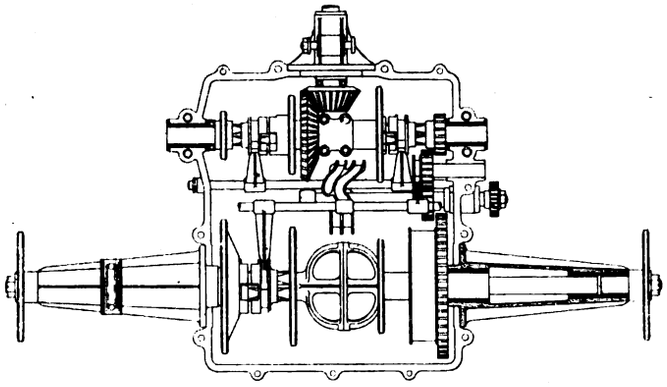

Fig. 4.—Sectional Plan of Change-Speed Gear on Brooke 15-20-h.p. Car.

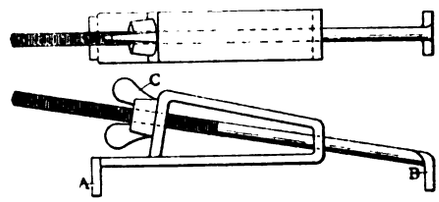
three years on Brooke cars, and after 17,000 miles on a vehicle weighing 23 cwt. the chains were found not to have lengthened, owing no doubt to the favourable circumstances under which they run. The bevel gears have ball thrusts fitted to them; the bevel pinion bearing is lubricated by a ring, the oil being kept at a constant level automatically from the gear box, a similar arrangement being provided on the sprocket shafts. From the differential shaft side chains transmit the power to the rear road wheels; the chains used are only 1 in. pitch, a very small size for so large a car; they have, however, special large rivets and a high breaking strain, and are claimed to be very silent in operation.

The control is from the steering wheel, two racks being provided therein, one for the throttle and one for advancing or retarding simultaneously the magneto and high tension ignition. Two switches are provided on the steering column casing, one for the magneto and one for the high tension, so that either can be used at will, or after starting on electric it can be switched off and the magneto switched on without the driver having to leave his seat. The hand brake is arranged on the same quadrant as the speed lever, and not only applies the metal to metal brakes on drums on the rear wheels, but also can be adjusted to withdraw the clutch if desired. The two pedals are of large size, and of the "push away" type. The left pedal operates the clutch and the right one a metal to metal brake within the gear-box. An accelerator pedal is also being fitted to control the governor in addition to the throttle control on the steering wheel. The dashboard is of the Mercedes type with inclined foot rest, and is fitted with coil, lubricator and pressure indicator. The coil is provided with both isolating and short-circuiting push buttons, and the lubricator is on the Dubrulle system worked by the pressure of the exhaust gases. The exhaust box is placed at the rear of the gear box and is fitted with a dust preventer. The petrol tank, which has a capacity of 9½ gallons, is located at the back of the car, with a large filling plug in an accessible position. The differential gear runs inside the gear box, and is constantly exposed to the action of the oil bath. The sprocket spindles are in one piece from the differential to the sprocket pinions, so that everything is cased in. A large inspection cover is fitted to the top of the gear box; it is fixed by catches instead of bolts, thus facilitating examination. The wheel base of the chassis is 7 feet 8 ins., and the gauge 4 feet 6 ins.; this, in conjunction with the long springs, makes it an exceedingly smooth-running car, which reflects much credit on its designer.

SOME USEFUL NOTES.

FEW things are more annoying or more difficult for the motorist to deal with than a water-circulating pump which persistently leaks. Such a pump is almost hopeless, because the defect can usually be traced to faulty designing, owing to the bearings not being long enough. When this is the case, the pump being driven by chain or frictional contact with the flywheel of the engine has the driving pressure applied at one point, thus causing the pump spindle to bear against opposite ends of the bearing. Now, the shorter such a bearing is the greater the wear will be, and so soon as this reaches an appreciable amount a permanent leakage will set in. This can only be cured by rebushing or lining the bearing, which would have to be repeated at very short intervals.

◆ ◆ ◆



INSTEAD of a long plain bearing, many pumps are fitted with a stuffing box and gland. Asbestos, tow, or other material is packed into the stuffing box and the gland is tightened up to make a water-tight joint around the revolving spindle. The stuffing box is the cylindrical chamber formed upon the body or cover of the pump. It is bored out considerably larger at its outer end than the diameter of the spindle, and is provided with an internal screw thread. The gland is simply a long sleeve fitting over the pump spindle. It is screwed to fit into the stuffing box, and is provided with a hexagonal head so that it may be tightened up with a wrench. Even the best of pumps will leak in time through the bearing becoming worn. When this occurs the best packing to use is one composed of alternate rings of rubber and hard fibre, which should be a good fit over the spindle. If the pump runs at too high a speed for the rubber rings to stand up to, then alternate the fibre rings—which should be at least one-eighth of an inch thick—with asbestos cord.

◆ ◆ ◆

THE Longuemare carburettors are made in so many sizes that it is often difficult to ascertain which is the right one to adopt. It may, therefore, be useful to mention that the most suitable carburettor for use with a certain engine is that which has a gas outlet pipe slightly larger than the admission port of the motor. Thus in the case of an engine having a gas inlet 39 or 40 mm. diameter, the carburettor having an outlet 41 mm. diameter should be adopted, while for motors with gas inlets of 20, 21, or 22 mm. diameter the one having a 22 mm outlet should be selected.

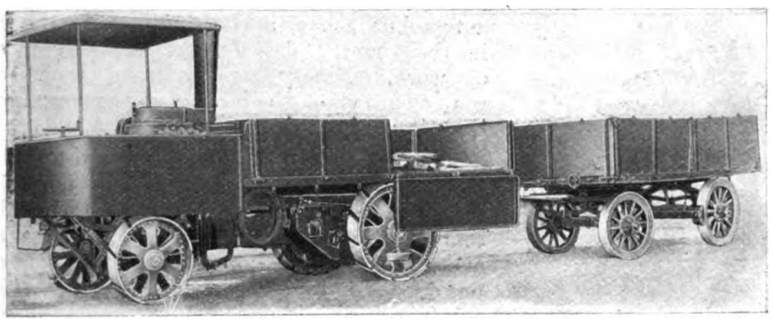
◆ ◆ ◆

THE accompanying sketch shows a little device which will be found useful in putting on automobile chains. The chain can be put on the two sprockets, and by the use of the device the ends may be brought together with ease. After the chain has been placed round the chain wheels the lugs A and B

are put through the end links, and the thumb nut C is screwed up until the connecting links are in such a position that the connecting bolt may readily be fixed in position.

IT is proposed to hold, under the auspices of the Aeronautical Institute, a series of trials of screw propellors, designed for aeronautical purposes. At first, only rotary propellors, and those up to about four feet in diameter, will be tested. For this purpose, the Aeronautical Institute will provide a motor of from ¼ to ½-h.p., together with all the other necessary apparatus except the actual propellors.

Digitized by Google



HERE AND THERE.

AN automobile club has just been formed at Novarra, Italy.

MR. A. E. MAJOR, of Reading, has purchased the well-known Serpollet car, the "Easter Egg."

THE West Surrey and Reading Automobile Clubs will meet at the George Hotel, Odiham, to-day (Saturday) at 4.30 p.m.

WE illustrate herewith a new Colonial type of steam wagon with trailer, recently introduced by the English Steam Wagon

Company, of Hebden Bridge. The vehicle is designed to carry five tons, and to haul three to four tons on the trailer. The general details of the boiler, engine, and system of transmission of the English steam vehicle were dealt with in the *Journal* of Nov. 28th last. As will be seen from the illustration, both the wagon and the trailer are fitted with sheet metal removable sides and ends to enclose the load.

THE Scottish Motor Garage Company, Ltd., of Glasgow, have entered a 12-16-h.p. Renfrew car for the Glasgow to London Reliability Trial. Its number will be 30.

A PROPOSAL has been made for the Motor Volunteer Corps to be provided with a machine-gun, which, it is suggested, may be carried with the gun attachment on a motor-car.

THE Clyde Cycle and Motor Car Company have opened a large garage at their depot in London Road, Leicester. It possesses every convenience for automobilists who desire to store their cars, including a complete repairing shop.

CONFIRMING our statement last week with reference to more motor-'buses being placed upon the streets of London, Mr. R. S. Tilling, at the annual meeting of Thomas Tilling, Limited, stated that £1,000 had been set aside for experiments with a motor vehicle which he thought would answer their requirements.

IN the report of A. W. Gamage, Limited, to be presented at the seventh annual meeting on Wednesday next, reference is made to the acquisition by the company of a building site adjoining the present premises, with a frontage of ninety-five feet to Holborn and a depth of 153 feet. This will cause the Black Bull Tavern, where Dickens gathered local colour for "Martin Chuzzlewit," to disappear, thus removing another of London's old landmarks.

A NEW tail lamp, designed to show not only a red light to the rear, but also to illuminate the number plate, has been introduced by Messrs. J. and R. Oldfield, of the Refulgent Lamp Works, Birmingham. The lamp, which is known as the "Dependence," is provided with double side lights, one of which illuminates the plate while the other throws a light on to the off-side, thus enabling the driver by a turn of the head to at all times assure himself that the tail lamp is burning.

A MEETING of the Birmingham Motor Express Company has been held, when it was resolved that the capital be increased from £5,000 to £20,000. It was also reported that additional cars would be placed on the Hagley road route the second week in May, and that the Watch Committee have granted the application of the company to work a quarter of an hour's service to Harborne.

THE Motor-Car Owners' Co-Operative Association will in future be known as Glaskin and Company.

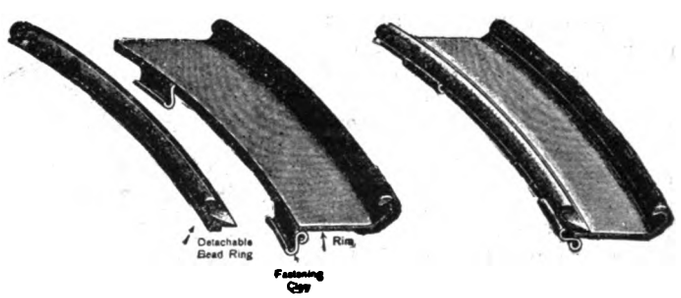
THE Motor Improvements Company, Limited, has been registered with a capital of £5,000, to manufacture and deal in motors, motor-cars, etc.

THE Elsworth Automobile Company are adding to their showrooms in Manningham Lane, Bradford, a department devoted exclusively to motor clothing and accessories.

LADY CURZON, who is staying at Deal, paid a visit to Walmer Castle on Monday, driving over in her motor-car.

THE Wolseley Tool and Motor Car Company, Ltd., are, we hear, about to invade the American market with "Wolseley" cars.

A COMPANY has just been formed in Venice with a capital of £12,000, to be known as La Societa Veneziana di Automobile Nautiche.



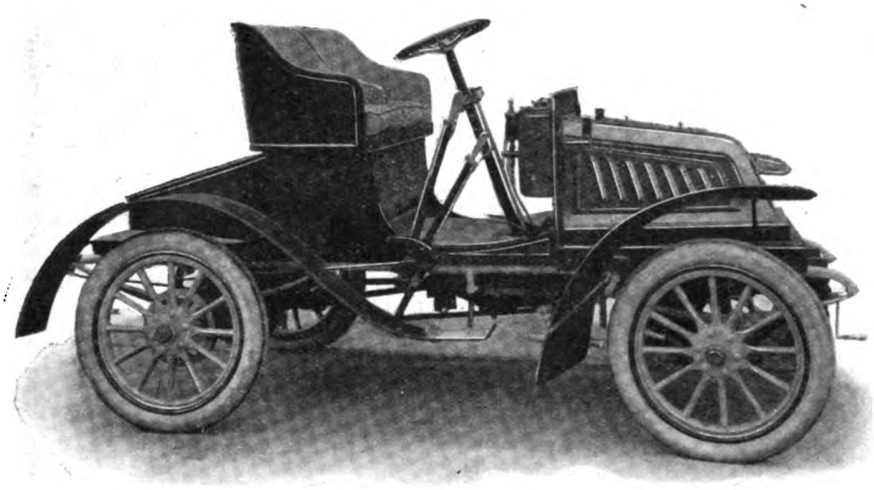
FROM the Continental Caoutchouc and Gutta-percha Company comes a new price list of "Continental" motor sundries, including repair patches, garters, jacks, tyre levers, etc.

TWENTY-NINE entries have, so far, been received for the Belgian Circuit des Ardennes. Mr. S. F. Edge and Mr. C. Jarrott are among those who have entered for the event.

THE Cadillac cars of the Anglo-American Motor Car Company, Limited, are, we learn, now being fitted with Clincher rims and Dunlop double-tube tyres 750 mm. by 85 mm.

"AHOY" is a liquid metal polish which the makers, the Hansa Chemical Works, are advising motorists to use on the brass work of their cars.

WE had an opportunity the other day of inspecting a new two-piece rim for pneumatic tyres which has recently been introduced by the Harburg and Vienna India Rubber Company, of Harburg, Germany, and London. The arrangement, which is designed to permit of the easy attachment and detachment of the beaded edge type of motor-tyres, is illustrated herewith. It will be seen that to one edge of the rim small hinged clips or claws are attached at intervals. Eight of these clips are fitted to the usual sizes of motor-tyre rims. The detachable ring, which is in one piece, has, in addition to the usual bead to receive the edge of the tyre, another small groove into which the ends of the clips fit. The more the tyre is inflated the greater the grip of the clips on the detachable ring, while even with a deflated or punctured tyre there is no danger of the



clips losing their hold on the ring, so the latter cannot come off accidentally. The new two-piece rim has already met with a favourable reception on the Continent, and, in view of its simplicity, should also quickly become popular in this country. The makers claim that it permits a tyre to be fitted on to a rim in less than two minutes, and this without using any tyre levers or other tools. All that is necessary is to fix the tyre and detachable ring in position and turn up the hinged clips so that the ends of the latter engage the groove in the ring, as seen in the right-hand illustration. The rim is made to suit all the well-known makes of beaded-edge motor tyres.

A NEW weekly illustrated journal for motorists has just made its appearance in New York under the title "Motoring and Boating."

UNIVERSAL AUTOMOBILES, LIMITED, is the name of a company registered to carry on the business of manufacturers of and dealers in motor-cars, etc.

The Anglo-French Mot Syndicate's 6-h.p. Mercury Simplex Car. (*See issue April 16th, page 157.*)

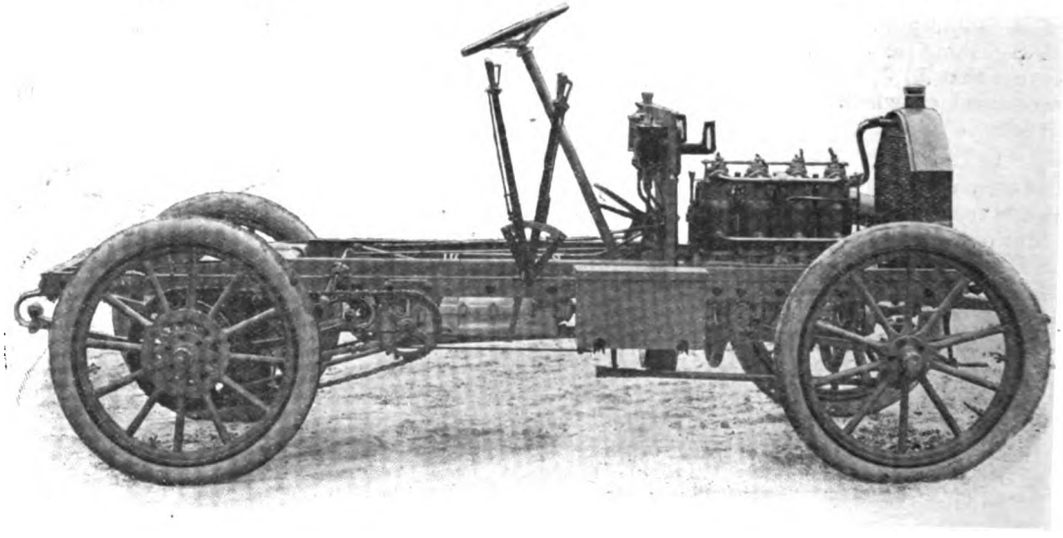
AN experimental plant for testing the power and efficiency of automobiles has been installed in the mechanical engineering laboratory of the Worcester Polytechnic Institute, at Worcester, Mass., U.S.A.

A PUBLIC meeting to advocate railway motor omnibus services in the Farnham and Haslemere districts was held at Wrecclesham Schoolrooms, near Farnham, on Wednesday. Mr. A. Harris, of the Farnham Potteries, is taking a lead in the matter.

LIEUT. the Hon. A. V. Verney-Cave and Messrs. Lindsay Bury and F. J. Frost, Motor Volunteer Corps, were engaged under the General Officer Commanding the Western District on a Staff ride in the neighbourhood of Bournemouth, at the end of last week.

ONE of the saddest aspects of motor driving is, says the writer of motor notes in the "Bystander," that "if one starts with a vehicle of low horse power it is absolutely certain that, sooner or later, its owner will desire to discard it for a car with more power and with a greater turn of speed. This has, in the ordinary course of nature, just happened to a neighbour of mine, who set off to the Crystal Palace recently, with a cheque in his pocket, where we happened to foregather, and spent some instructive hours "havering" with the various stallholders. Several times did he make the Sydenham pilgrimage, but the cheque remained—a blank. Then I met him later, at the Agricultural Hall, and in a corner of the gallery he suddenly met his fate. Merely a naked *chassis*, and, after a searching inspection by one of our best-known motor, *dilletanti*, the draft was drawn to pay for this identical and attractive skeleton."

THE Harrow District Council has decided to urge the Middlesex County Council to obtain powers, under the Motor Traffic Act, 1903, to close the road at Grove Hill, on which the recent accident occurred, to motor-cars.



ORDERS have been given for a second Mechanical Transport Company (to be numbered the 78th) of the Army Service Corps to be formed at Aldershot on the 1st of May. The first Mechanical Company (the 77th) is stationed at Chatham.

THE Young Men's Christian Association's automobile school at Boston, U.S.A., the first in the country, has finished its first session of work. Ninety certificates of proficiency were awarded, on the basis of written examinations in lecture and shop courses.

THE poetry of motion has its most exhilarating expression in the rhythm of motoring, remarks an American worker, who considers that if you have never sat at a steering wheel and enjoyed the delight of directing a safe and powerful car over beautiful country roads, drinking fresh air and feeling the thrill of a new life, you cannot realize how splendid a pleasure you are missing.

"KELLY'S CUSTOMS TARIFFS OF THE WORLD" has just been published by Kelly's Directories. Hitherto these have appeared in the same firm's "Directory of Merchants, Manufacturers and Shippers," but owing to the growing size of that volume the tariffs are now, for the first time, issued in a separate book which extends to seven hundred quarto pages with two closely printed columns to the page. Every care having been taken to ensure accuracy, the work will be of undoubted value to all commercial men.

AT Gamage's, in Holborn, a lamp called the "Zanardini" is now on view, in which there are no rubber bags to cause trouble. All the parts are get-at-able, and it is possible to turn the gas off and on constantly till the carbide is used up, as the water is driven out of the carbide chamber immediately the light is turned out. At a trial of motor lamps held by the Rhone Automobile Club in March, this lamp took the first prize and also won the gold medal of the Automobile Club of France in April, 1903. The front of the lamp is elliptical, the reflector parabolic, and the general ensemble sufficiently striking to attract visitors to the idea.

Chassis of 24-h.p. Prunel Car. (*See issue April 2nd, page 106.*)

CONTINENTAL NOTES.

The Bordeaux "Automobile Week."

THE programme of the Bordeaux "Automobile Week," which is to extend from the 8th to the 14th May, has just been issued. On the first day there will be a series of motor-boat races; on the 9th, a competition of touring cars, with an excursion to Medoc. The touring test will be continued on the 10th, on which day there will also be a run to the Sauternes district. On the 11th, an exhibition of cars and flying machines is to be arranged; on the 12th, a balloon and flying machine competition; and on the 13th and 14th, a trial of heavy motor-cars, including delivery vans and public service vehicles.

A new Spirit for Motor-cars.

LE COMPAGNIE DES ALCOOLS FRANCAIS have recently introduced a new alcohol fuel for motors, which they have named "Motoral," and which they claim will increase the power of high speed motors by fifty per cent. There is a certain proportion of water in the alcohol, which, it is claimed, gives rise to the increased power. When the charge is fired, the water is, it is stated, converted into high-pressure steam, which softens the force of the explosion and prolongs the action of the same on the piston. "Motoral" requires a larger air supply to the carburettor than petrol, while it will work equally well with a ten per cent. addition to the latter.

A Novel Motor-Cycle Competition.

THE Moto Club of Marseilles is organising a somewhat novel form of competition for motor-cyclists to be held in June next. It will be known as a "Rallie Postal Moto-cycliste"; each competitor when ready to start will draw a sealed envelope from a bag. In the envelope will be found instructions to proceed to a certain post-office in the district and bring back a letter from the poste restante. Thus the competitors will not know the journey they are to make until the moment of starting. The prize will be awarded to the rider performing his task in the shortest time.

Dispatch Carrying by Motor-Cycle.

SOME interesting trials of dispatch carrying by motor-cyclists were held last week under the auspices of the Austrian Ministry of War. As a basis of the tests, it was presumed that the telegraph and the railway services had broken down, and that the main roads were held by the enemy. The riders had, therefore, to make use of bye-roads, and in case of breakdown of the machine, it was understood that the journey must be continued, not by motor-car, or motor-cycle, as these would probably not be available in time of war, but by ordinary vehicles or bicycles. Two messages were sent at different times; the first one was in charge of two riders who conveyed it from Vienna to Kaumberg; here it was handed over to another couple of motor-cyclists, who hurried along with the dispatch to Hadersdorf. From this place to Laa another relay had charge of the message, and still another back to Vienna; the total time occupied in covering the 300 kilometres being 8 hours 29 minutes. The second message was sent over the same course, but in this instance only one rider had charge of it on each of the different stages. The dispatch was, however, successfully delivered round the circuit in 9 hours 33 minutes.

A Consumption Test at Marseilles.

THE Automobile Club of Marseilles is organizing a "Circuit au Bidon" for the 15th May. Before starting each car, with its full load of passengers, will be weighed and then given half a litre of spirit for each 100 kilogrammes. The course is from Trets to Pourcieux, and then almost to Aix, whence the cars will return to Trets. The winning car will be that which covers the longest distance on the petrol supplied.

The Paris-Bordeaux-Paris Motor-Bicycle Reliability Trial.

OF the sixty-eight entries which were received for the 1,200 kilometre reliability trial for motor-bicycles organised by the Autocycle Club de France, fifty-nine faced the starter at 6 a.m. on Friday last week. The riders were sent off in pairs at two minute intervals from St. Mande, the last being despatched just before 7 o'clock. The day's destination was Tours, a distance of 258 kilometres, forty-eight riders completing the journey. The first to reach Tours was Foulon on a Bruneau chain-driven machine, he arriving at 2.23 p.m., Olieslagers on a Minerva being second at 2.31 p.m. An early start was made on Saturday, the first of the forty-eight riders being sent off for Bordeaux at 5.5 a.m., amidst a heavy shower of rain. The distance to be covered was 342 kilometres (214 miles); a stiff day's journey, especially in view of the heavy roads, and it is not surprising that a number of competitors had to give up. The first to reach Bordeaux was Olieslagers (Minerva), who arrived at 4.56 p.m.; Kuhling on a Gobron-Minerva coming next at 4.59 p.m. At 10 o'clock on Saturday night only twenty-eight of the competitors had arrived.

Alcohol Exhibition at Vienna.

THE International Alcohol Exhibition was opened on Thursday last week at the Rotunda, Vienna, by Archduke Franz Ferdinand. Only Austria-Hungary, France, Germany, and Russia are taking part in the show, which is intended to illustrate the rapid development of spirit as an article for motor power, lighting, and heating. The Rotunda presents a marvellous collection of entirely new branches of industry which have sprung up within the last few years. The increased use of alcohol opens new prospects to agriculture, and it is thought that the losses which agriculture has sustained within the last thirty years by American competition may be compensated for by the production of spirit from potatoes. The French section has been well supported by automobile manufacturers in France, among the cars

Touring on the Continent.—A Stop at Laibach, Austria.

represented being C.G.V., Gardner-Serpollet, Renault, De Dion, Mors, De Dietrich, Clement-Talbot, Panhard, Darracq, Chaboche, Peugeot, Krieger, Brouhot, Gobron-Brillie, and Tony-Huber.

Speed Trials and Racing at Arras.

THE programme of the races at Arras in connection with the exhibition which is to be opened in that town on the 19th May has now been drawn up. In the afternoon of the 25th there will be a series of standing mile and flying kilometre speed trials on the Arras-Douai road; a kilometre hill-climb on the Doullens hill will be held on the 26th; a five-kilometre race will be run off on the 27th; while on the 28th there will be a touring competition from Arras to Touquet, via Boulogne.

Motor-Boat Racing.

THE entries for the second annual contest for the Gaston Menier Cup so far number nine, three of which are English. The trophy is to be competed for in Trouville roadstead on Sunday, August 21st, the distance to be covered being three miles. The French entries are:—M. H. Fournier, Hotchkiss; Georges Richard, Trefle à Quatre II.; M. Clement, Bayard; M. Legru, Gardner-Serpollet; and M. Dubonnet. The English competitors comprise a Napier, a Hutton, and a Thornycroft boat, while Germany will be represented by a Mercedes.

WE learn that the Southport Tramways Company has made arrangements for storing, cleaning and repairing motor-cars at its depot at Churchtown, Southport.

CORRESPONDENCE.

ACCUMULATOR CHARGING FROM PRIMARY BATTERIES.

To the Editor of *The Motor-Car Journal.*

Sir,—Can you assist me with any hints on the charging of accumulators? I have a four-cell Peto and Radford charging battery fitted with an adjustable wire coil resistance, but when newly charged, as per directions, I find that with the full resistance interposed there is still a current of about eight amperes, which is more than double the charging rate of my cells. What I wish to know is whether I can connect two cells in series, and let the full eight amperes through, so allowing four to each, which is the full charging rate; or if not, how can I reduce the current? Thanking you in anticipation.—Yours truly,

C. R. W.

[When a good primary battery is made up with fresh solutions, it gives its maximum voltage, and therefore offers a low opposing electromotive force to the primary battery, an excessive rush of current being the result. To overcome this difficulty, it is best to connect up three instead of four cells of the primary battery to the accumulator. This can easily be done, as the battery mentioned by C. R. W. is provided with separate terminals to each cell. After some little time the voltage of the cells will fall, and the voltage of the accumulator will rise, causing a fall in the strength of the current, in which case the fourth cell can be put in and the accumulator left until it is charged. C. R. W. in his query asks if he can connect two cells in series, but evidently two cells in parallel is meant, as it is only by connecting them thus that the current can be divided between them. This, however, would not help, as by so doing the opposing voltage is reduced. Connecting three cells up is the best method, and the resistance can be used to obtain exact regulation of the current.]

GENUINE DE DIONS.

To the Editor of *The Motor-Car Journal.*

Sir,—I desire to call attention to the fact that no De Dion Bouton 6 or 6½-h.p. car has been made with a three-speed gear, and cars thus described cannot be genuine De Dions. As such advertisements are frequently inserted in the motor papers, I shall be obliged if you will insert this letter to warn intending purchasers to make sure, before buying a car as a De Dion-Bouton, that it is really our make throughout, and not merely fitted with a De Dion-Bouton motor. We are always pleased to advise anyone on the subject if they will send us the number of the motor. This number is stamped on each half of the crank case on the right hand side when facing the timing gear.—Yours truly,

De Dion-Bouton, Limited.

VARYING VALVE LIFT.

To the Editor of *The Motor-Car Journal.*

Sir,—I notice in your account of the "Utile-Simplex" car you state that the exhaust valve has a variable lift. Surely this is detrimental to engine and valve on account of the back pressure caused when the valve has anything less than full lift. It is very noticeable with a small engine how soon it overheats (with consequent slower running) when the valve is not getting the full lift, and this must be considerably greater with an 8-h.p. engine. Would it not be a better plan to adapt a variable lift to the inlet valve, as this in itself answers the purpose of a throttle very well, and I have been surprised how much quieter the engine runs when the inlet valve is getting little or no lift. Having less distance to travel, the valve shuts with much less noise. Running the engine in this way with the ignition set, the speed can be varied from about 200 to 2,000 r.p.m. by simply giving the inlet more lift, this allowing a greater charge of gas to enter the cylinder. By giving exhaust valve less lift to obtain slower running you only over-heat the engine, but by leaving exhaust lift set, and giving less lift to inlet valve, the engine not only runs quieter but keeps much cooler; at least this is the effect on a 1¾-h.p. air-cooled engine, and I fail to see why it should not be so with a larger engine. I shall be glad to hear other readers' opinions on this subject.—Yours truly,

A 2,708.

A TRIP TO GERMANY FOR THE GORDON BENNETT.

To the Editor of *The Motor-Car Journal.*

Sir,—I propose travelling by road to Homburg for the purpose of witnessing this year's Gordon Bennett race, and shall be glad to hear from motor-cyclists desirous of joining in what cannot fail to prove a most interesting tour from every point of view. In laying my itinerary before you, I should like it to be clearly understood that I propose neither the shortest nor the most convenient route, but rather one leading throughout past picturesque country and rich in historical associations. Starting from London on June 11th, my route will be as follows:—London, Croydon, East Grinstead, Uckfield, Lewes, and Newhaven. After crossing, Dieppe, Neufchatel, Rouen, Pont d'Arche, Bonnières, Nantes, St. Germain, and Paris. So far the road has followed the Seine Valley, now it runs up that of the Marne as follows:—Meaux, Chateau-Thiery, Epernay, Chalons-sur-Marne, Verdun, Metz (then up the Valley of the Moselle), Luxemburg, Treves, Coblenz (or, alternatively, up the Valley of the Nahe), Saarlouis, Kreuznach, Bingen; from either Coblenz or Bingen up the Rhine to Mainz, thence across country through Hoechst to Homburg. The total distance to be covered by road is approximately 620 miles, for which I allow five days, thus providing an ample margin for sightseeing and all eventualities, and arriving in Homburg in time to go over the course previous to the race. I do not consider it advisable that those taking part in this tour should keep together, as this is always attended with difficulty in the case of motor-cyclists. My suggestion is, therefore, that by following the same route and meeting at predetermined halting places each noon and night, the desired result would be attained. Riders would soon sort themselves out and find companions of identical tastes in the matter of pace, wayside halts, etc. It is needless to point out the inadvisability of any but experienced riders taking part in a tour such as I have proposed. A working knowledge of French and German is also desirable. Those whom the matter interests will oblige me by addressing their communications to the Automobile Club.—Yours truly,

M. T. Tuchmann.

STEAM CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—As a user of paraffin burners I think what I have to say will interest "Locomobile" and "Steamer." I have tried most of the known makes of burners and also some of the unknown, but have, at the present time, a burner made by the National Burner Company that takes up no more room than the fire-box fitted to ordinary American steam-cars, being very similar in outward appearance. This burner is fitted with a pilot light and can be left for hours, ready to start at a moment's notice. I have run my car now 4,000 miles with this burner, and the average consumption of oil is one gallon for every twenty to twenty-five miles, with four passengers up.—Yours truly,

Superheat.

To the Editor of *The Motor-Car Journal.*

Sir,—In reply to "Locosurrey's" letter, I would strongly advise him to have a car fitted with a "flash" boiler if he intends using it for touring. The life of a flash boiler depends largely on the efficiency of the appliance fitted for regulating the proportion of fuel and water, as, in the event of this proportion becoming disturbed, the boiler obviously becomes either cold or unduly overheated.

In the case of the Miesse car this depends on the driver's judgment. The Serpollet system of oil and water pump having a constant proportion of stroke is a very good one, but inefficient working of either of the pumps at once disturbs the proportions of fuel and water, and causes trouble. When I was choosing a car, this was a point I gave considerable attention to. I finally purchased a Relyante steamer, which is built somewhat on Serpollet lines, but special attention and care has been paid to the design of the pumps to insure a constant efficiency. I have now driven about 3,000 miles, and never had the slightest trouble with my generator.—Yours truly,

J. L.

To the Editor of *The Motor-Car Journal.*

Sir,—I should feel greatly obliged if you could give me the names and addresses of makers of motor-cars or lorries which use paraffin or kerosene as a fuel instead of petrol. I am looking for a type of vehicle for use in the tropics, where petrol is both expensive and difficult to deal with. If any of your readers have had experience of the working of such engines I should be glad to know their views.

I have seen an extract from a foreign paper stating that a car with 8-h.p. engine of Leatch make, has been doing well in the Straits Settlements, but I cannot trace the firm who made it.—Yours truly,

F. H.

[Steam cars using paraffin as fuel are made by Turner's Motor Manufacturing Company, Limited, Wolverhampton, and the Cremorne Motor Manufacturing Company, Lots Road, Chelsea, S.W., both of which concerns will no doubt be glad to furnish particulars of their vehicles. We have no knowledge of a car known as the Leatch.—Ed. M.C.J.]

"PUMPING" MOTORISTS.

To the Editor of *The Motor-Car Journal.*

Sir,—As an example of the method which the police apparently are adopting of "pumping" motorists for their line of defence before taking out a summons, the following may be of interest and serve as a warning to others who may be the subject of this disgraceful practice.

At the end of last month a police officer in "mufti" called on me and informed me that a constable had reported the number of the car I was driving in the Essex Road, N., at 10.15 p.m., on the 22nd of the month, as belonging to a car which was not provided with a light so as to illuminate the number plate on back of car nor showing a red light in the opposite direction I was travelling. This being the first information about this matter I had from the police, I asked why the constable had not called out so as to draw my attention to it at the time. I was shown a copy of the report, and nothing suggested that the constable had made the slightest attempt to draw my attention to his assertion.

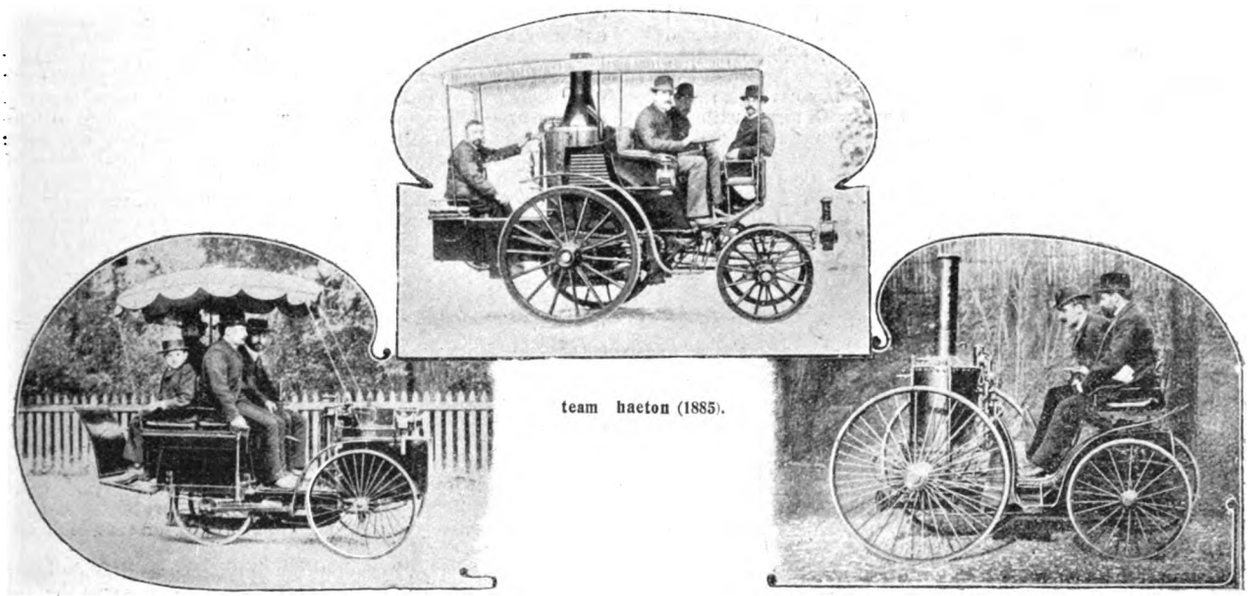
I further explained that the lamp was alight a short distance before and after the place where the constable was supposed to have seen the car, and that I had not been down to light it in the meantime, and that I had a friend with me at the time who would be able to bear out my statement.

Digitized by Google

In response to some further question, I said the constable had, no doubt, made a mistake owing to the bright electric light in the road having "killed" the smaller light of the lamp, and so, according to his report, he had not noticed the two red lights produced by the front lamps and showing towards back of car. This served to strengthen my opinion. The gentleman in "mufti," who said he had come to inquire into the case, was most civil, and thought I would probably hear no more about it as my explanation seemed very feasible and satisfactory. A few days after I, however, received a summons and, in consequence, had to appear at the North London Police Court, only the offence about not illuminating the number board being mentioned.

In defending the case I asked for the report, of which I had seen the copy, to be produced, as this would prove that the constable had overlooked the red lights and therefore would be more likely to overlook the number illuminating light, the latter being more the colour of the stronger light illuminating the road. This report could, however, not be produced in court, and upon questioning the constable he declared to have seen the two red lights before mentioned. After having raised a few more points the magistrate, however, considered the evidence sufficient to give me the benefit of the doubt and dismissed the case. The next day I heard that a similar inquiry had been made by the police in a case where the owner is accused of having driven above the legal limit; the inquiring "gentleman" left after having given a similar satisfactory opinion as in my case and a few days after a summons was served.—Yours truly,

F. WIEDEMANN.



is a gross exaggeration, as it would lead one to infer that the others of the party were unable to render any, which is not the fact. The reports were evidently constructed by a sensation-mongering reporter, probably because the owner of the car refused, shortly after the occurrence, to supply any information to an interviewer, in the idea that he would thus prevent horrors of the usual type gaining currency.—Yours truly,

WILLIAM E. MOSS, Hon. Sec.

COMPETENCY ON THE ROAD.

To the Editor of *The Motor-Car Journal.*

SIR,—Your correspondence *re* drivers is undoubtedly of the greatest interest to all concerned with the welfare of the industry, and I, for one, sincerely hope it will bear the desired fruit, viz., the weeding-out process, and give honour where it is due, and save the confusion and difficulty of trying to decide who is a genuine professional mechanician. The best men I have met with through the shops and on the road have shown the least swagger and the most consideration for their car and the other users of the road, and still upheld their own dignity with all the ability circumstances desired whenever the occasion for same arose. That a real good man is the positive cheapest there can be no argument, and to make a good man, on a piece of well-made, fairly complicated mechanism, dealing with the laws of speed and gravitation, and the unlevel surfaces of the various roads, carrying the lives of his employer and family and the other users of the road in his hands, having to contend with the nervousness of various horses, pedestrians, excited children, irate old gentlemen, foolish dogs, greasy sets, etc., and still keep going at a good speed, and as cool and

team haeton (1885).

A Steam Quadricycle (1885). A Belt-driven Steam Ca (1883).

SOME EARLY DE DION STEAM CARS.

TYRES AND CARBURETTORS.

To the Editor of *The Motor-Car Journal.*

SIR,—As a user of the Louguemare carburettor I would be very pleased if Thomas Hallewell would give fuller information as to fixing a shutter on the air inlet. The carburettor inlet pipe on my 12-h.p. car is fixed on to the exhaust pipe and is perforated round same. My air lever has no regulating rod to dashboard, and I have to regulate the air lever under the bonnet before starting, and it makes not the slightest difference whether the air lever is half open or wholly open as to the running of my car, no matter when running the engine free or when on the road.

If you or any of your readers can give me any information as to what should be done to improve matters I will take it as a great favour. I could easily have a rod on to the dash if this would assist, but my opinion is that the carburettor is not getting sufficient air. R. W. B. states that the jet may have been unduly enlarged; will he explain where said jet is to be found and how best to correct error? A hint on how to best get gear box wheels to mesh when changing speed will be of great assistance. I can change from lower to higher speeds all right, but when coming down, should I wait a second or should this changing be done quickly?—Yours truly,

MACK SICCAR.

SENSATIONAL REPORTING.

To the Editor of *The Motor-Car Journal.*

SIR—As there may be some inquiry respecting the accident to a Liverpool motorist, reported in the daily papers as having occurred on the Cat and Fiddle road last Sunday, I am glad to tell you I am authorised by the owner and driver of the car, who is a member of the Liverpool Self-Propelled Traffic Association, to write you.

To say that the gentlemen of the Imperial Yeomanry who kindly went for assistance "found the lady unconscious and apparently dead" pleasant as sitting on a chair, he wants all his faculties on board, which must mean, first, *prevention* by forethought and foresight in a degree that can only be got by absolute experience of a long-standing practical acquaintance with the nature of the metals and parts under his control. Second, *cure* (should it be needed), and how to turn, fit, forge, or braze or solder a spare part with makeshift tools anywhere from home, and so save being stuck fast, and this *promptly*. This means resource and mechanical ability of no small order. That is why men who possess these qualities can always get a job straight away at a works, with a greater freedom than usually offered in private, with not so many often reverse-opinioned persons to please, and also why menial duties, such as house or garden, are uninteresting and objectionable.—Yours truly,

W. C. READ.

DECAUVILLE CARS.—Mr. J. W. Hicks writes:—"I shall be glad if any of your readers would give me their experience of Decauville 10-h.p. cars.

THE "KOSMOS" TREADS FOR PNEUMATIC TYRES.—A correspondent enquires for the name of the English agent for these treads.

RADIATORS.—Mr. Frank Morriss, of King's Lynn, writes:—"In the last issue of the *Journal* I notice a description of a radiator made by the Coventry Plating and Presswork Company, Limited. May I be allowed to state that I made a radiator on this principle as far back as the end of 1902, and, indeed, exhibited the same at Cordingley's Show in 1903? I enclose you an illustration of one of my radiators, which are made in any shape desired and of various dimensions, suitable for cars of any horse-power. This type of radiator, when properly constructed, is most efficient and far stronger than the usual honeycomb type. Care must, however, be exercised in the design; it took me some time to arrive at the correct proportions, but I can supply a radiator of this type suitable for any car."

INTERNAL-COMBUSTION MOTORS.

By Dugald Clerk, M. Inst. C.E.

—♦—

The annual "James Forrest" lecture at the Institution of Civil Engineers was delivered on the 21st inst. by Mr. Dugald Clerk, M. Inst. C.E., who chose as his subject one that he is well qualified to deal with, viz., "Internal-Combustion Motors." Mr. Clerk covered the whole ground of gas and oil engines, but we have confined our abstract to those portions dealing with petrol and alcohol motors which are of particular interest to motorists.

During the past twenty-five years engineers have applied internal-combustion motors to all manner of uses in powers ranging from the tiny ½-h.p. motor to the huge 2,000-h.p. engine. They have adapted the motors to the consumption of many different kinds of inflammable gases and vapours, and they have continually increased both mechanical and thermal efficiency until, at the present time, these motors compete with steam in almost every field. For small and moderate powers their advantages greatly outweigh those of steam. Light hydro-carbons had been early utilised in these motors, but it required the advent of the motor-car, with the beautiful small high-speed engines originated by Daimler, to make petrol consumption a matter of commercial importance. The production of these petrol engines is now conducted in all countries on a very large scale indeed, and the desire to utilize local inflammable material has led to the use of alcohol in similar small motors specially arranged for that fuel. Much has been done, but more still remains to be done before finality can be said to be even approximately attained.

Much difference of opinion still exists on physical and chemical points of the highest abstract scientific interest; but all are agreed, so far as practice is concerned, on certain main features. These leading features are: initial compression of the working fluid, exposure of the flame to the smallest area of cooling surface for the shortest time; and the use of the lowest flame temperatures consistent with high available pressures. In many cases motors deviate somewhat from these understood requirements; generally not from ignorance on the part of the designers, but from some stern practical necessity. Some of these matters, both practical and scientific, will be here discussed. Development has followed two main lines. First, improvements relating to the motor itself, including changes in the thermo-dynamic cycle, followed in the treatment of the working fluid and the inflammable gas within the motor by the modification of such details as admission valves, igniting devices, governing methods and water and air-cooling systems. Starting-gear has also been carefully studied, and, both from the thermo-dynamic and the mechanical point of view, it may be safely said that these motors have attained a great measure of perfection. Secondly, parallel with the improvements relating to the motor itself have proceeded those relating to means of generating the inflammable gaseous or vapour fuel intended to operate the motor. These improvements have related to the economical production of ordinary coal-gas, to the effective production of producer-gas from anthracite, bituminous non-caking coal, coke and other solid fuels, to the treatment of heavy and light hydro-carbons and alcohol to produce an effective inflammable vapour, and to the purification and collection of blast-furnace gas, coke-oven gas and natural gas.

Car motors are very commonly made of the inverted vertical type, and they run at speeds of from 600 revolutions up to and even over 1,200 revolutions per minute. In these engines the cylinder and combustion spaces are well water-jacketed, and now both inlet and exhaust valves are usually positively operated. Ignition is effected electrically, sometimes by a magneto machine and sometimes by accumulator and induction coil and jump spark. Many varied types of engines, however, are now used for motor-car purposes, and it cannot yet be said that the motor-car engine has attained fixity of type, although for the present the inverted vertical engine is in the ascendant. Considerable variations in the construction of motor-car engines may be expected within the next few years. The magneto appears destined ultimately to supplant all other modes of ignition.

The present position of the theory of the internal-combustion motor is in the state of that of the steam engine at the time of Watt, before the accurate determination of the properties of steam. As Watt knew of the latent heat of steam but did not know all its properties accurately through a considerable range of pressures and temperatures, so engineers now know of a similar absorption or suppression of heat existing in gaseous explosions without knowing accurately its causes or proportions under all the various conditions of practice. It is perhaps in this task of settling the data for an accurate standard engine of comparison that the physicist and chemist can assist the engineer most effectively. So far, by following the broad lines indicated, heat efficiencies have improved from 15 per cent. to 30 per cent.; and, without doubt, further improvement in efficiency will be made, but with present knowledge it would be impossible to say that the next twenty years would carry us from the 30 per cent. efficiency of to-day to, say, a 60 per cent. efficiency. That efficiencies can be increased much further cannot be doubted.

Gas-engine constructors have noted that among all uncertainties there emerges one certain fact, that the higher the compression—or rather, the smaller the compression space relatively to the cylinder volume—the greater the economy to be obtained from the engine. They have seized upon this fact, and the past twenty-five years of English and continental practice have shown steadily increasing compression. Improvement in this direction may be considered as due to bettering the conditions of the thermo-dynamic cycle; but another line of improvement is also open, and that line is to reduce the heat losses to the lowest possible point. All internal combustion motors suffer large heat-losses because of the contradictory requirements of the practical cycle. The cycle requires a charge of working fluid first as cold as possible, then compression of that charge without heat loss or gain, then combustion producing high temperatures, succeeded by expansion, also without heat-loss or gain. In an ordinary internal-combustion motor of medium size these opposite conditions follow each other in the same cylinder at intervals of about one-sixth of a second, and in a high-speed petrol motor at from one-twentieth to one-fiftieth of a second. It is, therefore, impossible to arrange cylinder conditions to minimise heat-flow, because any attempt to keep surfaces hot to prevent heat-loss at once introduces heat into the working fluid at a time when it should remain cold. Some heat-loss, therefore, from the hot gas to the relatively cold walls is unavoidable. This loss, however, becomes naturally less and less with increase in the dimensions of the engine. With engines of similar proportions, the surface exposed for cooling flame increases as the square, while the capacity of the engine increases as the cube. From this it follows that the larger engines should lose less heat proportionately than the small ones.

As a rule it may be taken that gases which are rich in hydrogen are highly inflammable, and pre-ignite readily. Such dangerous mixtures can only be compressed to a moderate degree without risk. It has been found, for example, that in petrol engines the compression can be carried higher than in heavy oil-engines, and that with some kinds of heavy oil compression must be lower than with other kinds. On the other hand, it appears that, with alcohol as the inflammable material, compressions can be carried very much higher than with petrol. At present the engineer knows, from previous experience, that, if he carries his compression beyond a certain limit for a certain gas, he will at once make his engine relatively unworkable by frequent pre-ignitions. The great limiting element in all internal-combustion motors, so far as high compressions are concerned, is this one of pre-ignition. They are due to many causes; sometimes to a small incandescent part of metal or to a porous surface of metal within the cylinder; sometimes to a hot piston end; sometimes to an over-heated exhaust-valve; possibly to charred matter of carbon deposited in the cylinder. In all cases, however, pre-ignition occurs owing to the tendency of these engines to be over-heated.

Definite chemical information is much wanted on the ignition points of various gaseous mixtures when treated under internal combustion motor conditions in fairly large volumes. Experiments, such as chemists sometimes conduct, in narrow glass or metal tubes are of little use in considering this question of pre-ignition. Such experiments, if made, would require to be performed with comparatively large bodies of material exposed for definite fractions of a second to certain graduated temperatures.

This is found to be the case, but it is also found that in engines above certain dimensions the reduction of cooling surface can be pushed too far. This is due to the fact that an engine piston has to compress an inflammable mixture to high pressure before ignition occurs at all. If the products of the previous combustion be not entirely removed, then in a large engine the temperature remains so elevated that the initial or suction temperature of the engine is raised and at high compressions pre-ignitions occur.

This question of pre-ignition limits the engine designer in many ways, and it becomes absolutely necessary to preserve the inflammable mixture during compression at a temperature below its igniting point. Any inflammable mixture only requires to be sufficiently compressed to ignite without any other means of inflammation. Unfortunately the conditions of maximum economy in engines are also conditions which favour pre-ignition. In small motors pre-ignitions are rare and are not dangerous; in large engines they are unfortunately somewhat frequent, unless mean pressures be kept down and extensive cooling adopted, and when they do occur they are somewhat dangerous. It is unfortunate, also, that no exact knowledge exists as to the temperature of ignition of different gaseous mixtures, and the engineer has been obliged to accumulate very considerable knowledge of the subject by the simple process of pushing his compression with each gaseous fuel as high as he dare without producing pre-ignition. If with any fuel he produces pre-ignitions, then he at once alters his compression space and other parts, so as to reduce the compression.

With regard to vaporizing devices for using petrol, petroleum and other hydro-carbons, great progress has been made, and the advent of the motor-car has brought into the field a large number of able engineers entirely untrammelled by any considerations of precedent. Their efforts have resulted in extremely interesting constructions, which are highly successful in vaporizing and applying these fuels to the use of the motors. The question of carburettors for light oils presents many interesting scientific peculiarities, part chemical and part physical, which require minute investigation. Alcohol, too, has been pressed into the service, and its properties, chemical and physical, supply a fresh series of problems for the chemist, the engineer and the physicist. Remarkable results have been obtained in Germany by the use of alcohol. Professor Meyers' recent tests with alcohol engines prove astonishing efficiency to be obtained from this substance. It may be said, however, without exaggeration, that the whole world is now alive to the possibilities of the internal combustion motor, and the progress will be more and more rapid. These motors have almost fulfilled the expectations of those engineers who—like myself—have devoted a large part of their lives to their study and advancement. They are looking forward now to the completion of the work begun so many years

Digitized by Google

ago, and expect, at no distant date, to find the internal-combustion motor competing with the steam engine even in its latest form, the steam turbine, on sea as vigorously as it does at present on land.

CLUBS AND ASSOCIATIONS.

WEST SURREY.

THE annual general meeting of the West Surrey Automobile Club was held at the Lion Hotel, Guildford, on the 19th inst. Those present included Colonel Fairtlough, chairman; Messrs. E. and F. Baring-Gould, Buttemer, Crothers, Noble, Pullman, Ponsford, and Tessier. The accounts, showing a balance in hand of £13 on the year, were passed, and the committee for the current year were elected as follows: Colonel Fairtlough, Messrs. W. G. Crothers, Wilson Noble, J. F. Ponsford, E. E. Pullman, A. C. Tessier, and R. W. Buttemer.

The Club is taking active steps towards assisting in the laying of several trial patches of Westrumite in the neighbourhood, which it is hoped will lead to a considerable diminution in the dust nuisance so peculiarly obnoxious on the chalk and sand formations.

The first run of the season took place on Saturday, when Mr. J. H. Knight kindly entertained members to tea at his residence at Farnham. Eight cars, besides those of several visitors, took part, and the interest of the proceedings was added to by an exhibition of Mr. Knight's car built by himself in 1895, and the first petrol car made in this country.

LINCOLNSHIRE.

THIS club held a very successful meet at Grantham on Thursday, the 21st inst. Eighteen cars and cycles arrived at the George Hotel shortly after 4 o'clock, and their arrival was watched with considerable interest. It was an exceedingly pleasant afternoon for motoring, and many ladies took part in the trip. Some of the cars came from places as far distant as Gainsborough and Market Rasen, while others were present from Lincoln, Boston, Bourne, and Stamford. Mr. G. Linnell's car—a 12-h.p. Wolseley—which brought a party from Market Deeping, proved an attraction, as did also the Richardson cars. The array of motors in the hotel yard was inspected with considerable interest by many of the townspeople who assembled to witness the meet. The motorists also included Mr. H. T. Pilley and party (Boston) on an 8-h.p. Peugeot, Mr. B. Smith (Horbling) on a 12-h.p. Richardson, Mr. G. Garnett and party (Gainsborough) on an 18-h.p. M.M.C., Mr. F. Richardson and party (Sibsey) on a 10-h.p. Wolseley, Mr. and Mrs. Padley (Market Rasen) on a 6-h.p. De Dion Dr. and Mrs. de Beauvais (Ancaster) on a 7½-h.p. Daimler, Capt. and, Mrs. Lyall (Grantham) on a 7-h.p. Panhard, Mr. and Mrs. Jevons (Market Rasen) on a 9-h.p. De Dion, Dr. and Mrs. Sharpe (Brant Broughton) on a 12-h.p. Richardson, Dr. Gilpin and party (Bourne) on an 8-h.p. Peugeot, Mr. C. Nelson and the Rev. Wardle Hall (Lincoln) on a 4½-h.p. De Dion, Mr. C. J. E. Parker and party (Grantham) on a 10-h.p. Panhard, Mr. H. D. Tryon and party (Stamford) on a 10-h.p. Pick, Mr. R. M. Wright and Col. Harding (Lincoln) on a 12-h.p. Darracq, Mr. Wilkinson (Lincoln) on a 3-h.p. Ariel cycle, Dr. Benson (Market Deeping) on a 3½-h.p. Royal George cycle, and Dr. Stanton (Market Deeping) on a 1½-h.p. Royal George cycle. The motorists and their friends had tea together at the hotel, and commenced the return journey shortly after half-past five o'clock.

WOLVERHAMPTON.

SATURDAY was the opening run of the season of the Wolverhampton and District Automobile Club, the place selected for a visit being Newport, Salop. On reaching Wrottesley Park, where the cars assembled, a photograph was taken, amongst the seventy present being Mr. Trevor F. Young, 18-h.p. "Star"; Mr. T. T. Mills, 8-h.p. "Sunbeam"; Mr. F. Platt, 6-h.p. "De Dion"; Miss Smith (Oaken), 12-h.p. "Sunbeam"; Mr. S. R. Rhodes, 16-h.p. "Ariel"; Mr. G. Evans, 10-h.p. "Wolseley"; Mr. W. Evans, 20-h.p. "M.M.C."; Mr. Scott, 7-h.p. "Panhard"; Mr. Rochelle, "Gladiator"; Mr. F. Jenks, 8-h.p. "De Dion"; Mr. Arnold Mills, 7½-h.p. "Wolseley"; Mr. J. W. E. Stirk, 12-h.p. "Sunbeam"; Mr. W. G. Owen, 10-h.p. "Wolseley"; Mr. W. H. Evans, 10-h.p. "Wolseley"; Mr. Herbert, 5-h.p. "Humberette"; Mr. J. O. Evans, 10-h.p. "Wolseley"; Mr. A. E. Price, 6½-h.p. "De Dion"; Mr. J. Barnett, 24-h.p. "Wolseley"; Mr. B. Payne, 4½-h.p. "De Dion"; Mr. Edward Lisle, 12-h.p. "Star"; Mr. Percy Bayliss, 7-h.p. "Panhard"; Mr. E. Bayliss, 8-h.p. "Wolseley"; Mr. E. Lisle, jun., 7-h.p. "Star"; Mr. Lewis, 8-h.p. "De Dion"; Mr. T. Cureton, 12-h.p. "Sunbeam"; Mr. Louis Connolly, 4½-h.p. "De Dion"; Captain W. H. Haden (Siddeley), 7-h.p. "Star." In addition to the motor-cars, Mr. W. H. Jenks had a motor-cycle, and later on Mr. C. F. S. Boyes also joined with his motor-cycle, on which he has ridden 2,000 miles.

Leaving Wrottesley Park, the cars were soon on the Holyhead road, and making their way to Newport. Motorists must feel they owe a deep debt of gratitude to the Staffordshire County Council for the splendid way in which that body looks after the main roads. The Holyhead road was left at the Junction at Kingswood, then up the hill, over Kingswood Common, and the cars were in Shropshire, going through the village of Albrighton, and then on to the village of Tong, made famous by Charles Dickens in "The Old Curiosity Shop." There was a good view of Tong Castle. The motor-cars stopped in front of the Royal Victoria Hotel, Newport, and soon there was a collection of them close to one of the gates leading to the parish church, for the residents of the Salopian town to look at. Soon after tea the return journey was commenced.

THE STORAGE OF PETROLEUM.

MESSRS. BRADBURY AND COMPANY (Limited), motor-cycle manufacturers, of Oldham and Farringdon Avenue, E.C., have been summoned for having on their London premises 4½ gallons of petroleum which was found to exceed the proper flash point allowed by the Act. When the inspector under the Act called at defendants' premises in Farringdon Avenue on the 8th April he seized four drums of spirit. When tested it was found to give off inflammable vapour at 4 degrees above freezing point. Professor Redwood had no doubt that it would give off an inflammable vapour at zero Fahrenheit; 73 deg. was the legal limit. For the defence it was submitted that the company had acted in ignorance, but were perfectly willing to adopt what measures might be suggested. They took the greatest care. Mr. Alderman Smallman imposed a penalty of £10 and £4 4s. costs.

CASES DISMISSED.

THE journeys of two motorists returning from Tarporley races were interrupted by the police at the foot of Luddington Hill—which is described as a steep and dangerous incline, about three-quarters of a mile in length—who appeared before the magistrates at Eddisbury. One of these, John Taylor, of The Hollies, Gatley Road, Cheadle, was said to have come down the hill at a speed of 28 miles an hour. The constable who made the statement admitted that the car was stopped within ten or twelve yards, and the magistrates were satisfied that it was under control and dismissed the case.

THE first case under the Motor Car Act at the East Grinstead Petty Sessional Court has just been heard. Herbert Burbidge, of East Grinstead, was summoned for two offences at Forest Row on April 9th—one for failing to produce his license as the driver of a motor-bicycle under the conditions of the Act, and the other for using a motor vehicle with a registration mark fixed thereon in accordance with the Act, but which was not easily distinguishable by the police by night. Defendant explained that the bicycle was brought over from Crawley for him to try before making a purchase. He rode to Forest Row, and was mending the engine for nearly an hour. He told the constable he had no

Digitized by Google

driving licence, but secured one a few days afterwards. The lamp was an acetylene one, and he had previously turned it down while the bicycle was stationary. When he turned it up it did not burn well, and the letters were not brilliantly illuminated. The Bench decided that the case should stand over for investigation, and just before the Court rose the Chairman said they had considered the circumstances, and thought that defendant had been rather indiscreet, but that the offences were committed more or less in ignorance. The case would be dismissed.

EDWARD A. HELLMUTH, of Mona-terrace, Chiswick, appeared to answer a summons as the driver of a steam motor-vehicle for leaving the motor without taking due precaution against it being started in his absence. Constable 23 K R on the evening of April 8 saw the defendant, who was driving a light locomotive, pull up at a coffee-house in the Mile-end Road. He made up the fire and then adjourned to the coffee-house, and afterwards admitted that he had left no one in charge. During the whole time the engine was under steam. The defendant said he did take precaution against the motor being started. He screwed down both brakes and put the engine out of gear. He also locked the top gear so that it was impossible for anyone to start it. He put the valve in mid gear to prevent it going backwards or forwards. Had all the levers been moved it would not have started. The magistrate observed that the defendant appeared to have fulfilled the regulations, and apparently did all that he was required to do. The summons would be dismissed.

LETTERS OF IDENTIFICATION.

BELOW we give the letters of identification for the English and Welsh county boroughs.

Bath	F.B.	Lincoln	F.E.
Barrow-in-Furness	E.O.	Liverpool	K.
Birkenhead	C.M.	Manchester	N.

POLICE TRAPS.

AT Wallop (near Andover) P.S. Barton, of the Hants Constabulary, is becoming a rival of Sergeant Jarrett. He has devised a trap on the main road leading from Andover to Salisbury.

ON the Portsmouth Road, at Surbiton, the police have a measured quarter of a mile.

THE police trap at Bolney, on the Brighton road, during the first three days of April resulted in thirteen summonses.

CONVICTIONS AGAINST MOTORISTS.

Camborne	Furiously riding motor-cycle	2s. 6d.
Hanley	Unlicensed car	20s., etc.
Halifax	No light at rear	5s., etc.
Winchester	Driving to common danger	£5, etc.*
Ashton	No light	2s., etc.
Birmingham	No number	10s., etc.
Andover	Reckless driving	£1, etc.
Farnham	Failing to stop after an accident, contrary to Section 6 of the Motor Car Act	£5.

* Licence endorsed in addition to fine imposed.

COMMITTED FOR TRIAL.

AT Epsom Police Court on Monday Emile Richard, a motor engineer, of Tottenham Court Road, W., was charged, on remand, with the manslaughter of Frank Parkinson Job, while in charge of a motor-car on the Brighton Road, at Belmont, on April 4th. Mr. William Lewis, from the Public Prosecutor's Department, prosecuted on behalf of the Treasury, and Mr. Symons defended. The accused, when arrested, said that he had to choose between a motor-cycle and the cyclist, and he alleged that the motor-cycle did not leave him enough room to pass. The accused had a French driver's licence, but did not possess an English driver's licence. He was committed for trial, bail being allowed.

DEBATEABLE MATTERS.

IN the course of a paper read before the Society of Arts on Popular Motor-cars on the 20th inst., Mr. Mervyn O'Gorman gave the following list of debateable matters on which the public have various views :—

Engine :	(i.)	Multiple	*v.*	Single cylinders.
	(ii.)	Vertical	*v.*	Horizontal engines.
	(iii.)	Small enclosed	*v.*	Large flywheels.
	(iv.)	Racing bonnets and cellular radiators	*v.*	Unobtrusive bonnets and gilled tubes.
Frame and Gear :	(v.)	Valves in pockets	*v.*	Valves in cylinder head
Control :	(vi.)	Spray carburettor	*v.*	Surface wick and others.
	(vii.)	Induction supply of gas	*v.*	Pressure supply.
	(viii.)	Side chains	*v*	Direct drive, live axles (this fashion has lately received the order of right-about turn).
	(ix.)	Four-speed sliding gear	*v.*	Two-speed of any other type.
	(x.)	Governing by throttling the inlet	*v.*	Throttling exhaust, hit and miss, altering mixture, &c.
	(xi.)	Long wheel base	*v.*	Springs properly damped.
	(xii.)	Heavy	*v.*	Light cars (here the turn is coming.)
Body :	(xiii.)	Ornate Carrosserie	*v.*	Simple and smooth bodies.
	(xiv.)	Wheel Steering	*v.*	Tiller steering.
	(xv.)	Racing results	*v.*	Reliability trial results.

MESSRS. H. MILLER AND COMPANY, LIMITED, of Birmingham, send a copy of their new catalogue. In glancing through this we notice that twenty-seven designs of cycle and motor lamps are illustrated, so that the firm is in a position to meet practically all classes, from the humblest motor-cyclist to the motor autocrat. There are too many lamps to describe in detail, the designs embracing patterns to burn either acetylene gas, petroleum, ordinary vegetable oil, or candle. In addition to lamps, Messrs. Miller and Company have added a spec ia chemical department to their business, and are in a position to supply burning and lubricating oils. These are put up in special tins enamelled in colours, which make an attractive display for the trade. They also supply repair outfits, cements, and non-inflammable solution, and are making a speciality of ordinary carbide.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to THE EDITORIAL DEPARTMENT, MOTOR-CAR JOURNAL, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non-compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

The Editors do not hold themselves responsible for the opinions expressed by their correspondents, or for statements and facts which do not appear in the editorial columns.

The Editors and Publishers beg also to state that they will accept no responsibility for unsolicited contributions, even if used, unless payment for same is directly specified in forwarding, and the terms arranged before publication.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, MAY 7, 1904. [No. 270.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

IT would appear that May-day parades of automobiles are likely to become a familiar feature in all the big centres of population. Not only was there the motor-van parade in London on Saturday last, but the Automobile Club of America has also made a beginning in having a May-day parade of automobiles, the date, however, being fixed for the first Saturday in the month, owing to the 1st inst. falling on a Sunday. The Mayor of New York will probably head the procession, and many public men have promised to take part in the event. The display is to be practically confined to motor-cars for touring and pleasure purposes, but the main point of interest is that on both sides of the Atlantic the automobile should be figuring in a parade which has hitherto been almost wholly identified with the horse.

◆ ◆ ◆

Fighting the Dust Nuisance at Wandsworth.

WE are glad to notice that Wandsworth is taking a prominent part among Metropolitan boroughs in inaugurating experiments with the view of combating the dust nuisance. The long straight thoroughfare known as Trinity Road, connecting the town with Balham and Tooting, has been selected for the trials, and the other evening men were engaged in sprinkling a stretch of the road, by means of the ordinary watering carts, with a solution of a new dust layer or binder known as Hope's Pyne Oiline. A further piece of the same road is, we understand, to be shortly treated with Westrumite for the purpose of ascertaining which preparation is the more effective and durable. Whether Wandsworth's enterprise is due to the fact that its Mayor, Mr. J. W. Lorden, has lately joined the ranks of automobilists, or to the growing automobile traffic along its main thoroughfare, which forms part of the high road from South London to Richmond and Kingston, we do not know, but the example it has set is one we strongly recommend to other Metropolitan boroughs.

◆ ◆ ◆

A Trade Distinction.

FOR the first time the automobile has made its way to the agenda paper of a trade union assembly, and at the Scottish Trade Union Congress just concluded the following resolution was submitted on behalf of the Coachmakers' Society:—"That, seeing the motor-car is a growing industry, the congress is of opinion that the structural work, apart from the power section, belongs exclusively to the coachmaking trade, and deprecates any attempt on the part of any other trade to claim or encroach on such industry." This having been seconded, it was moved and seconded by the delegate of Furnishers, that, not having sufficient information before them, the congress declined to commit itself to an opinion which might prove inimical to the interest of their trades and lead to friction between them and the congress. In the discussion which followed, the general opinion was that the resolution by the coachmakers would lead to serious disagreement among the trades, and that the object of the congress was to unite the trades and not place barriers between them. The amendment was carried by 69 against 8.

◆ ◆ ◆

In the Park.

IN the House of Commons on Monday Lord Balcarres, in reply to a question by Mr. Cathcart Wason, said that since the beginning of January there had been only one summons for excessive driving of motor-cars in Hyde Park, as compared with 108 during the whole of 1903, an improvement which is as creditable to the police as to the motorists. The limitation of speed in Hyde Park does not come under ordinary law, but under the Parks Regulation Act of ten years ago. These regulations provide that the speed should be such as the traffic requires, and that it should be reasonable.

◆ ◆ ◆

No Speed Limit.

WHILE on this point we would advise the coroner of the city of Durham not to place too much reliance upon the idea of a speed limit as affording safety to the public. In a case in which an old lady had been knocked down and killed, the witnesses agreed that a speed of six or seven miles an hour had not been exceeded. The coroner suggested that no one should travel through the narrow streets of the old city at more than four miles an hour. Even this restriction would not be satisfactory. The law should deal with cases of driving to the common danger in such circumstances, for speeds that are perfectly safe in one place are simply murderous if indulged in at another time in another place.

◆ ◆ ◆

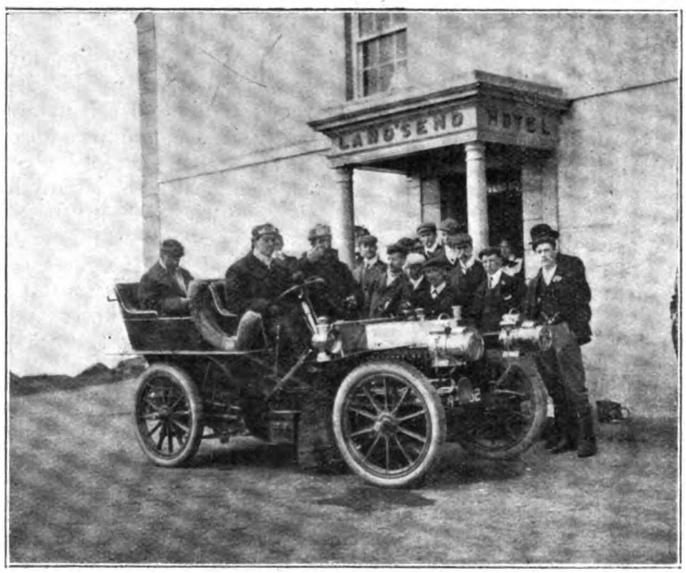
In the City.

THE Common Council of the City of London have decided to make application to the Local Government Board for regulations in pursuance of sub-section 9 of the Motor Car Act of 1903, putting its provisions into force in the whole of the City of London. This will mean that throughout the City no persons will be allowed to drive a motor-car at a speed exceeding ten miles an hour, an exceedingly reasonable suggestion, against which motorists will have nothing to say. In fact, there is really no reason for the Act to be put into operation, as the provision is already carried out by every sensible motorist. We doubt whether the traffic will allow a speed of anything like the rate suggested, and it may safely be said that the City of London will occupy a unique position in the fact that it is likely to be the only place in the United Kingdom where the Local Government Board will readily approve of the reduction of the speed limit to ten miles per hour.

◆ ◆ ◆

Motor Cycles and the Yeomanry.

IT would seem that the automobile is becoming really ubiquitous in the Army. The other day Mr. Allhausen asked the Secretary for War whether he would sanction the use of a limited number of motor-cycles in lieu of horses for despatch carrying, ordinary work, or other purposes by Imperial Yeomanry during their annual training. Mr. Arnold-Forster was sympathetic to the extent that he replied that there would be no objection to the use of a "very limited number" of motor-cycles



Digitized by Google

in the way suggested by the M.P. for Hackney, provided that the proper training of Yeomanry in the use of horses was not in any way inteferred with. On the question, however, of the owners of motor-cycles being permitted to draw an amount equivalent to the allowance to existing owners of horses, as a forage allowance, he was decidedly reactionary, and curtly answered that the proposal could not be sanctioned. We do not despair, however, for it will be remembered that when the use of the motor-car in connection with the military manœuvres was suggested, the War Office declined to treat owners of cars with anything like generosity. The good work, however, that has been done has convinced the War Office of the absolute necessity of encouraging the use of the automobile, and the cars having proved their value, it only remains for the motor-cycle to do likewise for its owner to be compensated. This is but right, for he places his machine as well as his services at the disposal of his country.

◆ ◆ ◆

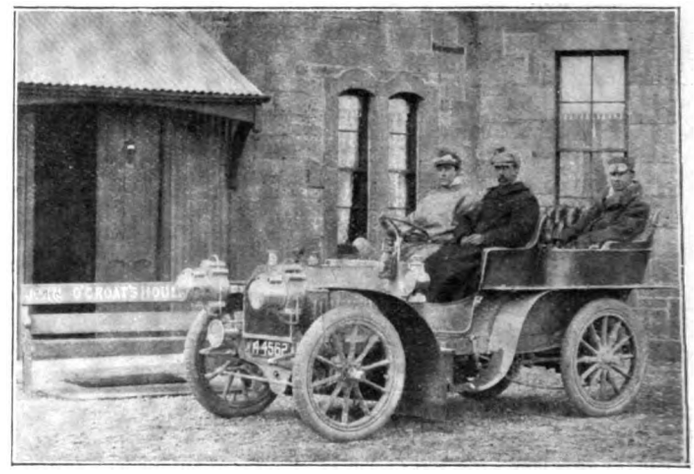
A 2,000 Miles Run.

MR. CECIL EDGE is to be congratulated on his feat in performing a run of 2,000 miles on a motor-car. Unfortunately he was not able to accomplish the task he had set out to do without a stop, but managed to break at least two world's records, and from that point of view the trip was eminently

The Napier Car at Land's End—

successful. Recently a non-stop run of 1,000 miles has been made between London and the Midlands, but Mr. Edge travelled 91 miles more than that without a stoppage of the engines. He started on April 25th from London, and arrived at Tewkesbury the next day, having first called at Land's End. On Monday he was up among the Grampians, plunging into a mountain stream, without, however, stopping the engines. Tuesday night he reached Dingwall, after having stopped at John o' Groat's sufficiently long enough for the accompanying photograph to be taken. Wednesday he got to Shap Fell, but unfortunately up the hill the cover of one of the tyres burst, necessitating a delay till another arrived. Thursday night was spent at Warrington, and on Friday morning, last week, he arrived just before 10 o'clock at New Burlington Street, London, subsequently going to Brighton and Worthing and ultimately finishing the run at the Automobile Club, having covered a distance of 2,068 miles.

◆ ◆ ◆



A Severe Test.

MR. CUNDY shared with Mr. Edge the handling of the steering wheel, and very little rest did they get during the week. The burst tyre must have been recognised by both as a providential incident, enabling them to get a little sleep while waiting for the new tyre to arrive. The trip was singularly free from incident, although three chickens, a calf, and a lamb ceased existence in consequence of the overbearing attitude adopted by the car towards these unfortunate beings. From start to finish the time occupied was 136 hours, and in going from Land's End to John o' Groat's, the distance of 865 miles, the actual running time was less than forty hours. Previously to this, the best run was that of Mr. Douglas Whitehead, who accomplished the trip in 45 hours 13 minutes. In endeavouring to demonstrate the strength and durability of an English motor-car Mr. Edge certainly succeeded, the only mishap on the car itself being the breakage of two chains, but otherwise the vehicle demonstrated the sturdy character of British productions.

◆ ◆ ◆

Alcohol for Motorists.

A NEW factor has been introduced into parliamentary life by the development of the automobile party of last year into a permanent committee, including practically all the motorists on both sides of the House. A meeting was held last week, at which Messrs. C. E. Shaw, C. D. Rose, W. Palmer, Hudson Kearley, Major Jameson, and Col. Sadler represented all shades of political feeling. They were, however, able to unite in their enthusiasm for automobilism. Mr. Scott Montagu, who was in the chair, must have felt that he presided over a body which is likely to be of considerable influence in the near future. Among the other matters discussed was the question of the duty on alcohol imported for industrial purposes, and it was decided to present a petition to the Prime Minister and the Chancellor of

And at John o' Groat's.

the Exchequer, urging that spirit imported for purely industrial and non-potable use should be received free on the lines laid down by Mr. Tyrer at the Society of Mechanical Industry to which we made reference in our last issue.

◆ ◆ ◆

The Aid of the Chemists.

THE hope of the Parliamentary Party is that the Government may consent to appoint a small committee of experts to investigate the matter and to make some definite report to the Treasury which may have the effect of securing the desired concession. If such is done, the chemists of the country, like Mr. Ormandy, will doubtless join in the movement by carrying out further experiments likely to assist the movement for the utilisation of alcohol in connection with motoring.

◆ ◆ ◆

Motor-Cars and the Post-Office.

AS was briefly mentioned in the *Journal* for the 23rd ult., the night mails between London and Epping have for some time past been conveyed by a 16-h.p. Milnes-Daimler car belonging to Mr. George Hayes, of Plumstead. The vehicle leaves Mount Pleasant, W.C., every night at 11.50 p.m., and runs *via* South Woodford, Woodford Green, Buckhurst Hill

Digitized by Google

and Loughton, short stoppages being made at each of these places to deliver mails at the sorting offices. Epping is timed to be reached at 2.8 a.m., and ten minutes are allowed for unloading the car and reloading it with local mails for the metropolitan district. The return journey, which starts at 2.18 a.m., is made *via* Chingford, where further mail bags are picked up and Mount Pleasant is again reached at 4.20 a.m. The service, which has been experimentally run for the past eight months, has proved so successful that, we learn, the G.P.O. authorities have decided to put it on a permanent basis, and have arranged a three years' contract with Mr. Hayes, who is having a new 16-h.p. van of the same type built for the purpose. The Post Office have two other motor-cars in use in the London district by way of experiment—an 18-h.p. Durkopp, which is conveying the night mails to Redhill, and a "General" light van, which is used for short journeys in the Metropolitan area. In the latter class of delivery work the automobile has proved its capabilities to the satisfaction of the postal authorities, who, we understand, are contemplating putting a number of additional cars in service at an early date.

Financial Success.

THE Board of the Hozier Engineering Company, Limited (makers of the Argyll motor-cars) have declared an interim dividend for the half-year ending 31st March at the rate of 20 per cent. per annum. The half-yearly dividend on the 6 per cent. preference shares will be paid on the same day. The dividend on the ordinary shares for 1902 was 5 per cent. and last year 10 per cent. This notable success of a British company will be gratifying to our readers and distinctly encouraging to the shareholders in the concern. Doubtless the company would assign as the chief reasons for their success the standardisation of parts, adhering to one pattern right through the season, the adoption of modern labour saving machine tools, the use of a most complete set of jig fixings and gauges, and, of course, the securing of a large market which enables them to have a continually growing production which has now reached fifty cars per month. To these factors might also be added Mr. Alec. Govan, the managing director of the company.

Photo by] The Eliminating Contest in the Isle of Man. A View of the Course Between Ballacrane and Glen Helen. *[G. B. Cowen, Ramsey.*

Cars at Cardiff.

REALLY some of the Welshmen are too tenacious in their campaign against motor-cars. We refer, of course, to the stubborn minority and not to the great bulk of the people, who readily recognise that the automobile is opening up a great deal of their beautiful country for touring purposes, and thus adding something to the wealth of the mountainside, to say nothing of the fashionable resorts along the seashore. Newport, of course, has proved obstinate, but we are glad to say that the Cardiff Cabs Committee has rejected an attempt made to restrict the speed of motor-cars to a ten-mile limit when passing through that important commercial centre of the Principality. The question arose last week on a report of the Chief Constable to the effect that the total amount of fees received in connection with the registration of cars and the licensing of drivers was £142, the details being as follows:—Cars, 42; motor-cycles, 103; car drivers, 154; cycle drivers, 50; manufacturers registered, 10; total 359. The chairman of the committee pointed out that up to the present drivers had been given a little latitude, till the working and provisions of the Act became a matter of common knowledge. If, however, any abuse of the privileges which they have been given takes place prosecutions will have to be instituted, and the chairman therefore warned motor-car drivers of the attitude likely to be taken in future. We would wish that the chairmen of all local authorities were as sensible as the gentleman who presides over the deliberations of the Cardiff Cabs Committee.

The Blackheath Club.

LAST week we recorded the formation of the Blackheath Automobile Club. It has quickly got to work and held a very successful inaugural run last Saturday. Although the day was dull and rain threatening, fourteen cars, one tandem, and two motor-bicycles arrived at the meeting place, where the photograph on page 225 was taken. A start was made about 3 o'clock for Seal Chart, near Sevenoaks, and there thirty-seven members and friends sat down to tea, which was served at the Sir Jeffrey Amherst. Subsequently some of the members took the opportunity of impromptu runs on the fine roads, and hill-climbs on the steep gradients adjacent to Seal Chart, whilst others visited the Pine Woods. A start home was made about 7 o'clock, and all who took part enjoyed the opening run and

Digitized by Google

were enthusiastic as to the future of the Club. The members taking part in the run included:—Messrs. L. Beadle (8-h.p. Regal), H. A. Cunis (5-h.p. Humberette), C. Chittick (6-h.p. De Dion), O. F. Flather (6½-h.p. Century tandem), J. H. Fraser (12-h.p. Hurst), Dr. Goodall (6-h.p. Stirling), B. Kingsworth (6-h.p. Panhard), Professor Carlton J. Lambert (6½-h.p. Talbot), F. Nichols (14-h.p. Renault), H. Norfolk (14-h.p. Renault), S. T. Norfolk (8-h.p. Renault), J. S. Prestige (10-h.p. Panhard), J. T. Prestige (14-h.p. Talbot), A. Roberts, hon. sec. (7-h.p. Daimler), and A. F. Yarrow (7-h.p. Panhard). The Club has decided to affiliate with the Motor Union, and Lord Hugh Cecil, M.P. for Greenwich, has consented to act as president.

◆ ◆ ◆

"Nervous Wobblers."

In the case at Winchester the other day when Earl Russell was threatened with the endorsement of his licence, Lady Russell described one of the witnesses as a "nervous wobbler." He was a cyclist with the same careless disregard of decision in crossing the road as some pedestrians evince. Unfortunately this is not an isolated example of the road pest, for this class of road nuisance turns up everywhere, and Lady Wimborne was the victim of an accident caused by a foolish cyclist in Dorsetshire the other day. It appears that a cyclist who was proceeding in the same direction as her ladyship's motor-car for some unaccountable reason swerved right in front of it. The driver immediately turned the car, and brought it under the bank and avoided the cyclist, who again turned into the motor, and was thrown off. There was no room to bring the car out from the bank until clear of the cyclist, and this left little room for the turn which was necessary to avoid a brick culvert, which the car struck when almost stopped. The cyclist, who, but for the prompt action of the chauffeur, would probably have lost his life, rode off without offering to render assistance.

◆ ◆ ◆

Irish Services.

In the House of Commons, on Tuesday, Mr. W. Redmond showed some solicitude with regard to the proposed motor-car services in Ireland, which have been so persistently boomed during the last few years. It was with some sort of satisfaction, however, that Mr. Wyndham was able to announce that this service would be started as soon as the necessary steps were completed for putting the roads in order in various parts of the country. Unfortunately, the Irish local authorities do not always recognise the advantage it would be to their local prosperity if they carried out their duties in connection with the roads of their particular districts. For instance, only last week, at the meeting of the Mountbellew District Council, the question of a motor-car service between Ballinasloe and Mountbellew was considered, Lord Clanbrock and others writing in support of the scheme. The County Council reported that it would require something like £1,300 to put the roads and bridges in a condition to render the service at all acceptable to the district. Immediately this was made known, the Council rejected the proposal by a large majority. Apparently the wiseacres on this estimable local body failed to see the fact that such a large amount would have to be expended in order to put the roads in a satisfactory condition indicates that they have wilfully neglected their duties in the past.

◆ ◆ ◆

The King's Visit.

It is to be hoped, however, that one result of the present visit of the King and Queen to Ireland will be the recognition on the part of the people of the wisdom of overhauling their roads with a view to putting them into a condition equally as good as those on this side of the Irish Sea. On Tuesday His Majesty went for a motor trip through the heart of the Blackwater country from Lismore Castle, where he has been staying as a guest of the Duke of Devonshire. Fortunately the roads in that particular district have had some sort of attention since the motor tour of last year. No less than five motor-vehicles took part in the trip, that of Lord Dudley being driven by the Lord Lieutenant himself. In the pilot car was Mr. Penrose, the Duke of Devonshire's agent. This preceded the canopied one, in which was His Majesty with the Duchess of Devonshire and two of the house party. In the next car the Duke of Devonshire, wrapped in a red padded coat, had the front place next the chauffeur, and in the covered body of the vehicle the Queen sat, wearing her green travelling dress, with fur storm collar. There were three open cars following, one of them driven by the Marquis of Waterford.

◆ ◆ ◆

Motor-Car Mishaps.

Accidents continue to be reported from many quarters, mostly owing to the errors of drivers of horse-driven vehicles. One of the most serious has occurred near Seaford. The car was going down a very steep hill outside the town, and apparently got out of control. It rushed down the descent, and dashed into a huge tree. The force of the impact with the tree must have been frightful. The front of the car penetrated the tree, which was a very large one, several inches, and it took some considerable time to extricate it. The wrecked car was afterwards taken away from Seaford by rail. The passengers, a lady and gentleman, were thrown a distance of twenty or thirty yards, sustaining slight injuries. The driver, however, was badly hurt, but the latest reports are that he is progressing favourably.

◆ ◆ ◆

The Inland Revenue and Motor-Cycles.

The case O'Donoghue v. Moon, in which a revenue officer appealed against a decision of the justices of Bristol dismissing an information for keeping a motor-cycle without a carriage licence, was heard in the King's Bench Division on Wednesday. The Solicitor-General, in supporting the appeal, pointed out that the Customs and Inland Revenue Act of 1888 described a carriage as a vehicle "drawn by horse or mule, or drawn or propelled upon a road or tramway or elsewhere other than upon a railway by steam or electricity or any other mechanical power." The only question, therefore, was whether a motor-bicycle was a vehicle "drawn or propelled by mechanical power." He submitted that it was, and that an Excise licence should be taken out. The matter was made still clearer by the Light Locomotives Act of 1896, which said that a "light locomotive," a definition which included a motor-bicycle, was "to be deemed to be a carriage" within the meaning of the statute. The Lord Chief Justice gave judgment, allowing the appeal, and said that it seemed to him that a machine which carried a person along the road was not the less a carriage because it contained a very uncomfortable seat, and one which shook the rider about very much.

An Automobile Club for Rhodesia has been formed at Bulawayo. Mr. A. R. Atkey, of Nottingham, was present at the inaugural meeting and gave some useful advice.

Mr. Charles Cordingley is reducing his automobile stud and is desirous of disposing of his well-known 40-h.p. Mercedes. Inquiries respecting the same may be addressed to the office of the *Journal*.

The leading tyre companies have appointed agents in all the more important centres in the Isle of Man, the principal being Messrs. J. and W. White, Prospect Hill, Douglas; Brooke and Co., Parliament Street, Ramsey; and T. W. Ratcliffe, Engineering Works, Castletown.

The track at Ladbroke Grove, W., which was originally intended to be used for the side slipping competition to-day (Saturday), will not be ready in time. It has therefore been arranged with the Locomobile Company that the trials will take place in their riding school, which has an excellent asphalte floor. The surface will be made greasy with a preparation of soft soap.

THE ELIMINATING TEST IN THE ISLE OF MAN.

ON Monday morning next, at 10 a.m., the eleven cars that will take part in the Eliminating Test in the Isle of Man will be weighed at Douglas.

THE EIGHT HOURS TRIAL.

Then on the following day (May 10th), an eight hours' trial will take place. This is intended to be:—(a) A high speed reliability trial, including: (b) Speed tests against time over half a mile on the flat in each circuit. (c) Speed tests against time in climbing a hill in each circuit. (d) Acceleration tests from rest and stopping observations. (e) Observation of the skill and suitability of the driver. (f) Examination of condition of cars at termination of trial. The course will be divided into sections, and a maximum and minimum time will be fixed for each section.

The cars will start at five minutes' intervals in the order given in last week's *Journal*. The first car will start at 9 a.m. from the railway crossing close to the Quarter Bridge, one mile west from the town of Douglas. If within one minute of the word to "go" being given a car does not start, the driver shall then move the car to the side of the road, and it will not be permitted to start until all the other cars have departed, but the driver shall proceed to make ready to start, and note will be taken of the time so occupied.

A View of the German Gordon Bennett Course at Konigstein.

Small triangular green flags signify "Drive with caution for 440 yards." Large green flags signify "Corner to be negotiated in 300 yards." Large red and green flag signifies "Stop in 300 yards." Large red flag means "Stop."

The following will be the controls:—

	Mls.	Fgs.	Minimum time. Mins.	
1. Ballasalla (inward) to Castletown (outward)	1	3	4	The town of Castletown is 1 mile 3 furlongs from the beginning of the control.
2. Foxdale (stop and start)	—		—	For the purpose of negotiating railway bridge.
3. Kirkmichael ...	0	4	2	Control extends through village.
4. Ramsey	0	4	2	Through the outskirts of the town.
5. Willaston Corner to Quarter Bridge	1	4	3	Passing through no villages but on a winding road. Outward end of the control at Quarter Bridge.

The total distance round the circuit, including controls, is 51 miles 1 furlong.

Replenishments of fuel, water, and oil can only be made within the Ramsey control, at the outward end, and at no other.

There will be two speed tests in each circuit, viz., half-mile on the flat and about 2¼ miles hill climb. The half-mile speed test on the flat will commence about one mile after passing Ballaugh Old Church. The start of the half-mile, which will be indicated by a flag marked "START" (which can be seen at some distance), will be taken flying, and the end of the half-mile will be indicated by a flag marked "FINISH," which will also be taken flying. Passing, if necessary, is permitted between Ballaugh Old Church and the end of the speed test. The Hill Climb will commence from a standing start at the outward Ramsey control, and will finish at a point 2 miles 480 yards beyond, the rise being approximately 1,019 ft. The end of the Hill Climb will be indicated by a flag marked "FINISH," and will be taken flying. Passing during the Hill Climb is permitted. After passing the end of the Half-mile Speed Test, and again after passing the end of the Hill Climb, ordinary speed can be resumed, as a car need not arrive at the next control before the expiration of the minimum time for the stage.

When a car has run eight hours, including the time in controls, it will be stopped at the finishing point at Quarter Bridge on next arriving there.

Passing will not be permitted except—

(*a*) in controls by the direction of the Control Marshal;
(*b*) on the two speed sections; and
(*c*) in the case of a car being in obvious difficulties.

In selecting the team, consideration will be given to the skill and suitability of the drivers, as demonstrated in the acceleration tests, in the accuracy of coming to rest on entering controls, in speed tests, in promptness in getting away from controls on the word to start being given, and in the general management of their cars. At the close of the Trial on the Tuesday the cars must be placed in the custody of the Club, and no adjustment, repair, or other work shall be done to them until after examination by the judges, which will not be concluded until 12 o'clock (noon) on Wednesday, May 11th. It is not necessary that the ratio of gears used in the selection trials should be the gears used in the Gordon Bennett Race, but they must not be altered during the four days in the Isle of Man, after weighing on Monday, May 9th.

HILL-CLIMBING TEST.

On Wednesday, May 11th, at 3.30 p.m. competitors will be required to take part in a hill-climbing test on a hill about one mile long near Ramsey. A competitor who does not take part in, or who is late for the hill climb may be disqualified from selection for the Gordon Bennett team, as the results of this hill climb will be taken into consideration in making the selection.

ACCELERATION AND SPEED TRIAL.

On Thursday, May 12th, at noon, competitors will be required to take part in an acceleration and speed test on the Parade at Douglas. The cars will be timed from a standing start in order to test acceleration, and after a run of a quarter of a mile will be timed over a flying kilometre.

THE Sligo Motor Service Company has been registered with a capital of £750 to run motor or other cars, vehicles, or engines for the conveyance of passengers or goods between Sligo and Rosses Point, and between Sligo and Bundoran.

EARL RUSSELL has entered into the necessary sureties for the purpose of appealing to the Hants Quarter Sessions against the decision of the Winchester justices fining him £5 and costs for driving to the danger of the public at Kingsworthy.

AT a meeting of the Aberdeen County Road Board, a discussion took place in regard to a letter from the Secretary for Scotland, in reply to the application by the County Council for the restriction of motor-car traffic on certain roads in the county. Mr. Graham Murray was of opinion that such restriction should not be imposed until it was seen how the statute operated. By ten to seven votes, however, it was resolved to recommend the County Council to reaffirm their former deliverance on the subject.

Digitized by Google

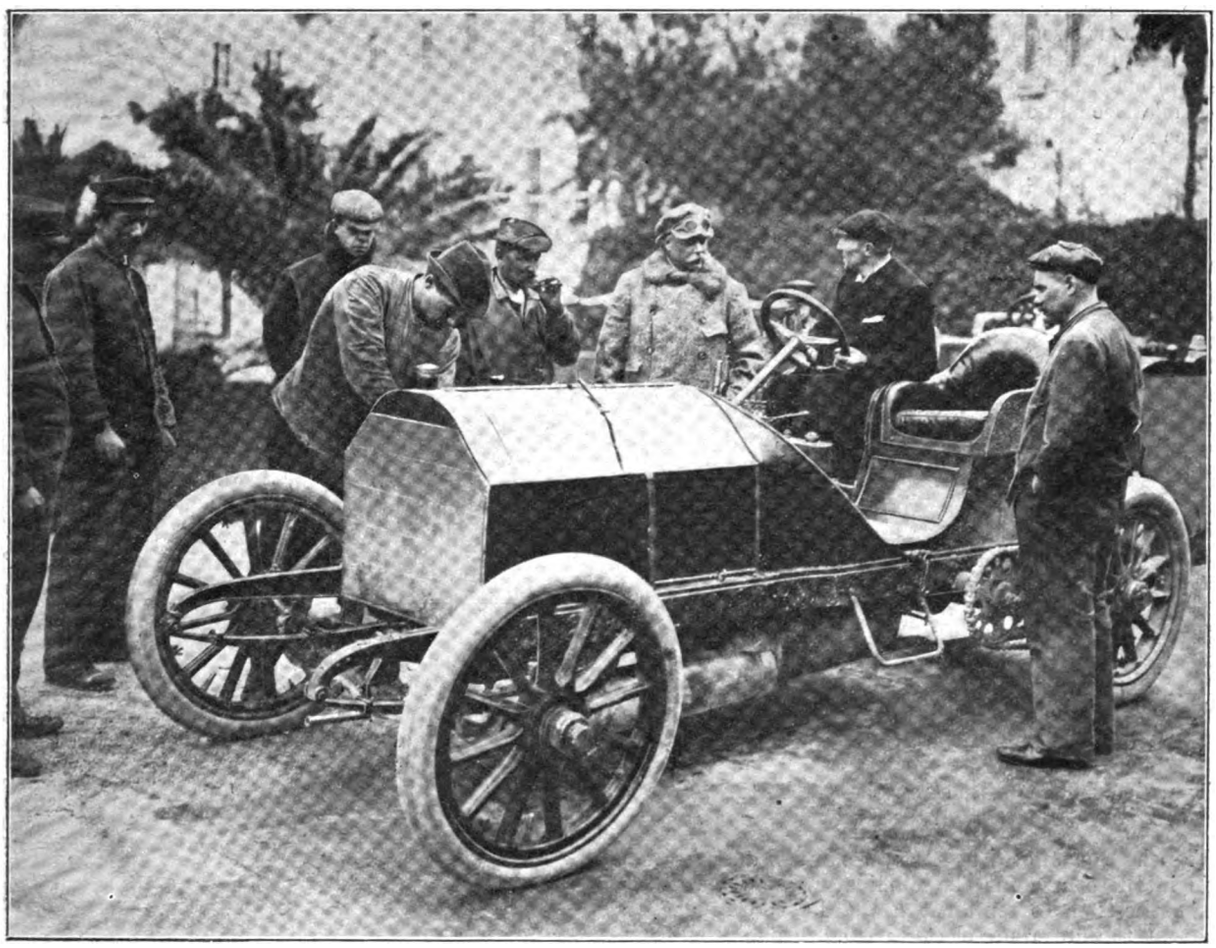
GORDON BENNETT RACE NOTES.

DR. DAVIES, who had charge of the ambulance classes in Ramsey, has been appointed Hon. Police Surgeon by his Excellency the Lieut.-Governor during the races, and there will be an ambulance station at the Municipal Offices. Dr. Davies has been asked by Col. Freeth, who has the matter in hand, to secure the services of some half-dozen certificated ladies who attended his classes, and these will be supplied with the Red Cross badges. Stretchers and bearers are also to be provided.

◆ ◆ ◆

BOTH the Manx Northern and the Isle of Man Railway Companies have generously agreed to suspend all traffic on the day of the race, a matter of no small importance, inasmuch as the course is intercepted by railway lines at four separate points.

◆ ◆ ◆



THE German Automobile Club has issued a warning to motorists that in the interests of the safety of the general public they must adhere to the police regulations when travelling over the Gordon Bennett course. The police have had instructions to stop all offenders, who will be liable to have their driving certificate withdrawn.

◆ ◆ ◆

BARON PIERRE DE CRAWHEZ met with an accident the other day which will probably prevent his driving in the French eliminating contest. While examining his car, the Baron's middle finger was badly injured by being caught between some gear wheels.

◆ ◆ ◆

ONE of the Pipe cars which will represent Belgium in the Cup race has just made its appearance on the road. It is stated

M. C Jenatzy on the 80-h.p. Mercedes at Nice. [*Allgemeine Automobil Zeitung.*

◆ ◆ ◆

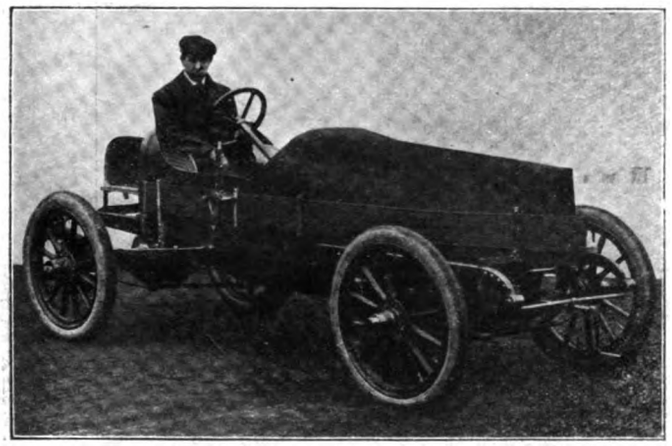
THE Napier headquarters during the course of the Gordon Bennett Eliminating Trials in the Isle of Man will be the Bay Hotel, Douglas. Many of the members of the A.C.G.B.I. will be staying at the Peveril or the Villiers Hotels.

◆ ◆ ◆

THE Vacuum Oil Company have, we understand, made arrangements for adequate stocks of their Vacuum mobiloils and greases in the Isle of Man. Mr. J. R. Corlett, of Victoria Street, Douglas, and Mr. F. Gash, Castle Street, Douglas, will, in addition to keeping the Vacuum mobiloils, also be able to effect repairs to cars, and provide garage accommodation. Messrs. Brooke and Company, Parliament Street, Ramsey, are offering similar facilities for motorists, and at the Villiers Hotel, Douglas, and from Mr. Hampton, on the South Quay in the same town, the Vacuum oils may also be obtained.

to have engines capable of developing up to 100-h.p. A committee of the Belgian club has been appointed to examine the three cars to ascertain if they conform to the regulations.

◆ ◆ ◆



BARNEY OLDFIELD, who has been disqualified by the American Automobile Association for taking part in unlicensed race meetings, is no longer connected with the Winton Motor Company. He is reported to have immediately entered into negotiations with the Peerless Motor-Car Company with a view to driving the car which this concern has entered for the American Gordon Bennett team.

◆ ◆ ◆

FOLLOWING the reopening of the entries for the team to represent America in the Cup race, comes the announcement of a formal application of the Winton Motor-Carriage Company for a position on the team.

Digitized by Google

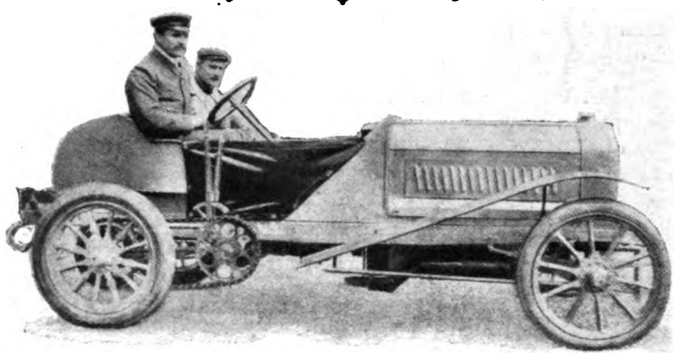
THE Peerless Motor-Car Company, of Cleveland, have sent us particulars of the car they have built for the American team for the Gordon Bennett race. We give an illustration of the vehicle with Mr. L. P. Mooers at the wheel herewith. The car, which is of the live axle type, is provided with a four-cylinder engine nominally rated at 50-h.p. In the particulars sent us by Mr. Mooers it is stated that three automatic inlet valves are provided in the head of each cylinder, and that the sparking plug is in the centre of the head between these valves. All four cylinders are cast in one piece. There are in the racer no especially radical differences from the Peerless standard four-cylinder cars, the main thing being, of course, that this car is bigger and more powerful all around. The wheel base is 8 feet 8 inches, and the tread 4 feet 6 inches. The radiator consists of sixteen five-sixteenth inch copper tubes lying close to the bonnet, and extending from the rear around the front and back to the rear on the opposite side. The water tank holds about eight gallons and the petrol tank about twenty-two gallons. The front wheels are 34 by 3½ inches in diameter, and the rear wheels 36 by 4½ inches. The bonnet is rounded and comes to a sharp point, so that it greatly resembles the end of a canoe inverted. The mixture and spark advance levers are mounted on the steering wheel. Four speeds forward and a reverse are provided. One of the interesting points of the car is its light weight, viz., about 16 cwt. 80 lbs., so that it is well within the limit. The lighter the car—

Mr. L. P. Mooers on the 50-h.p. Peerless Racer.

keeping always in mind requisite strength—the better the tyres and wheels will, it is claimed, stand the strain.

◆ ◆ ◆

THE French Minister of the Interior has caused an alteration to be made in the course for the eliminating contest on the 20th inst. for the team to represent France in the Cup race, on the ground that the first route elected passed through too many villages and comprised too many sharp turns. The new course is only 92 kilometres long, and runs from Mazagran to Vouziers, and thence *via* Le Chesne (where the new route commences), Louvergny, Bouvellemont, Tourneur, Neuvizy, Rethel, and back to Mazagran. The course will have to be covered at least six times, and as in each circuit there are four neutralisations, each of the twenty-nine competing cars will have to be started and stopped twenty-four times.



◆ ◆ ◆

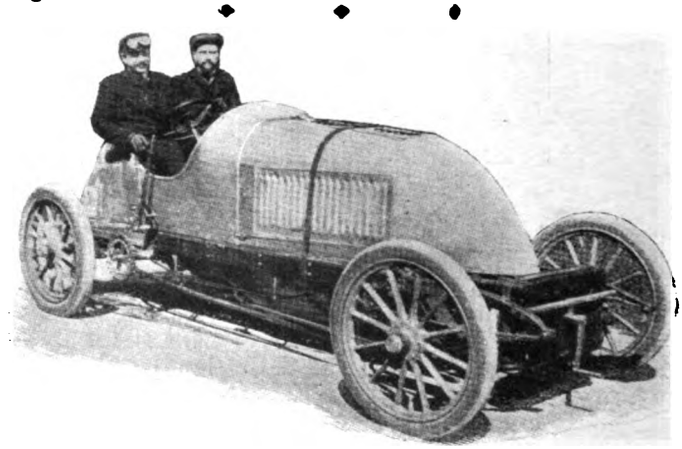
THE Sporting Committee of the A.C.F. has fixed Mazagran, between Rethel and Vouziers, as the starting point of the French eliminating race. Mazagran is a lonely spot represented by a single roadside cafe, seven miles from Attigny, the nearest railway station. The weighing in will be commenced at 10 a.m. on the 19th inst. The best way, by road, from Paris to the starting point is *via* Chateau-Thierry, Rheims, and Attigny.

◆ ◆ ◆

L'AUTO is organising a special train to the French Ardennes for the Eliminating Trials on the 20th inst. Under the arrangements, the train will leave Paris on May 19th at 7.10 p.m., and will be so arranged as to serve within easy distance of every point of importance on the course. The return journey will be on May 20th, starting from Vouziers at 6 2 p.m., reaching Paris at 10.20. The charge for a seat in the special train is 70 fr. Dinner and dejeuner will be served *en route* for respectively 7 fr. and 5 fr. (wine not included).

◆ ◆ ◆

M. Caillois on the George Richard-Brasier Racer.



◆ ◆ ◆

AS was announced in the *Journal* a month or so ago, the 1904 Panhard Gordon Bennett racers will be of the cardan shaft and bevel gear driven type. The cars have, it is stated, four-cylinder engines of 100 h.p. The cylinders are of steel, with copper water-jackets shrunk on; mechanically-operated inlet valves have been adopted, and both magneto and high tension ignition are fitted. The vehicles are now undergoing their preliminary road trials.

◆ ◆ ◆

THE De Dietrich racers are now completed and are on the road. So are the Mors cars, of which little or no particulars are available. It is stated, however, that one of the principal features is to be found in the engines, the crank shafts being set slightly in advance of the cylinder axis. Although new to Mors, this is not a novel departure, as an English concern—the Putney Motor Company—have been making their Craig-Dörwald motors in this way for some time. It is claimed that by thus setting the crank shaft forward, both shock and vibration are reduced owing to the direct thrust on the driving stroke, and that in addition there is a mechanical advantage at the end of the compression stroke. The Darracq racers are also now out on the road undergoing their trials. They are identical with those built in England, of which we gave an illustration in a recent issue.

◆ ◆ ◆

M. H. Fournier on the Hotchkiss Racer.

◆ ◆ ◆

THE arrival of the Wolseley racers attracted much attention at Douglas, where Lieut.-Colonel Mayhew arrived on Tuesday. The Wolseley cars are garaged at Okell's Brewery. The Darracqs will be put up in the Steam Packet Co.'s shed on the Battery Pier; and the Napier cars at the Bay Hotel. Mr. Jarrott and Mr. Campbell Muir are staying at the Peveril.

THE MAY DAY PARADE.

THE scene on the Thames Embankment on Saturday last, when eighty-two motor vans drew up for the first annual motor May-Day parade of such vehicles, was hardly a picturesque one. The names on the vans were entirely of the utilitarian order, and even when, some hours after the assembly commenced, the parade moved westward, it could hardly be said to be in accord with the poetry of motion.

The truth is that heavy vehicles do not present the attractiveness to the public that light cars do, and on this account the event failed somewhat as a spectacular effort. Nevertheless, it was a useful innovation, and should have a great educational influence in demonstrating to business men, and those concerned with the industrial world, that the motor-vehicle is being adapted to a strictly commercial purpose. The Midland Railway, for instance, had two Milnes-Daimler lorries, each of 9½-h.p., and the great carrying firms like Pickford, Carter Paterson, and C. Webster were represented not merely by an isolated vehicle, but by a "stud" of three and four each. This proves that such experts in the transport of goods recognise that the motor-vehicle has gone beyond the experimental stage, and that they are justified in steadily adopting automobiles. Purveyors of foods and condiments seem to have taken kindly to such vehicles, and Bird's Custard Powder and Allenbury's Foods proclaimed the reliability of the automobiles. Brewers and similar traders have evidently gone seriously into the business. Messrs. Watney, Coombe, Reid and Company, Fremlin and Company, and J. Dewar and Sons also sent vehicles. An important section was that of vans for municipal purposes, the City of London Corporation and the Westminster Borough Council sending contingents. It is to be regretted that Chelsea, which was a pioneer in this movement, and has five vehicles of the Lancashire Steam Motor Company, should have declined to allow any of its wagons to take part in the parade. The caravan restaurant attracted much attention, illustrating a development that should appeal to all classes of the community.

Very few incidents occurred; one of the vehicles bore the highest number we have yet seen, viz., A. 5008. The ascendency of steam in this department is shown in the fact that twelve petrol and one electric comprised the total that were not propelled by steam.

In addition to the heavier classes of vehicles, a few lighter vans propelled by motor-power were also included in the Parade, and considerable interest was taken in the White steam cars, utilised by Messrs. Liberty and Company for their fashionable West-End trade. The Bryant and May van was another striking vehicle, and that of Messrs. Warings, with its spick and span green tints and highly polished brass work, appealed strongly to the popular imagination.

Unfortunately for the spectators the judging of these vehicles occupied a considerable time and proved a very monotonous operation. The judges began their work at 3 o'clock, and it was nearly 6 o'clock before they had gone the whole length of the procession as it was drawn up on the Embankment.

It was to be noted, however, that among the onlookers were a considerable number of interested gentlemen who regarded the parade from a purely business point of view, and were present in order to take stock of the progress that the movement has made. Thus it served a very good purpose, and, although popular interest seemed somewhat lacking, that should not at all dishearten the organisers of the parade, who may be assured that a good many prospective users of motor-vehicles were among the observers. Mr. Basil Joy is to be congratulated on the efficiency with which he carried through the details of the afternoon.

The following vehicles were found by the Judges to be in first-class condition and so were awarded a first prize:—

Description.	Owners.
Wallis Tractor and Trailor	Wild and Robbins.
Foden Tractor and Trailer	Chislehurst Mineral Water Co.
Milnes-Daimler Delivery Van	Bird's Custard Powder.
Thornycroft Steam Wagon	Allen and Hanbury.
Yorkshire Steam Wagon	Allen and Hanbury.
Thornycroft Steam Wagon	J. Dewar and Sons.
Straker Steam Wagon	Carter, Paterson and Co.
Lancashire Steam Motor	Mann, Crossman and Paulin
Fischer Petrol-Electric Van	Hampton and Sons
Milnes-Daimler 'Bus	G. Hayes
Thornycroft Steam Wagon	Schweppes Ltd.
Thornycroft Steam Wagon	Searcy, Tansley and Co.
Lancashire Steam Motor	Bryant and May
Straker Steam Wagon	Provincial Carriers
Thornycroft Steam Dust Cart	City of Westminster
,, ,, Water Cart	,, ,,
,, ,, ,,	,, ,,
Straker Steam Wagon	Piggott Bros. and Co.
Thornycroft Dust Cart	City of London.
,, ,, ,,	,, ,,
Clarkson, Ltd.	Hamilton and Co.
Lancashire Steam Motor	H. Greenfield and Co.
Straker Steam Wagon	Dorman, Long and Co.
Thornycroft Restaurant Van	Caravan Restaurant Co., Ltd.
Thornycroft Steam Wagon	British Vacuum Cleaner Co.
White Steam Van	Liberty and Co.
Thornycroft Steam Wagon	Sanderson and Sons
Straker Steam Wagon	T. and W. Farmiloe, Ltd.

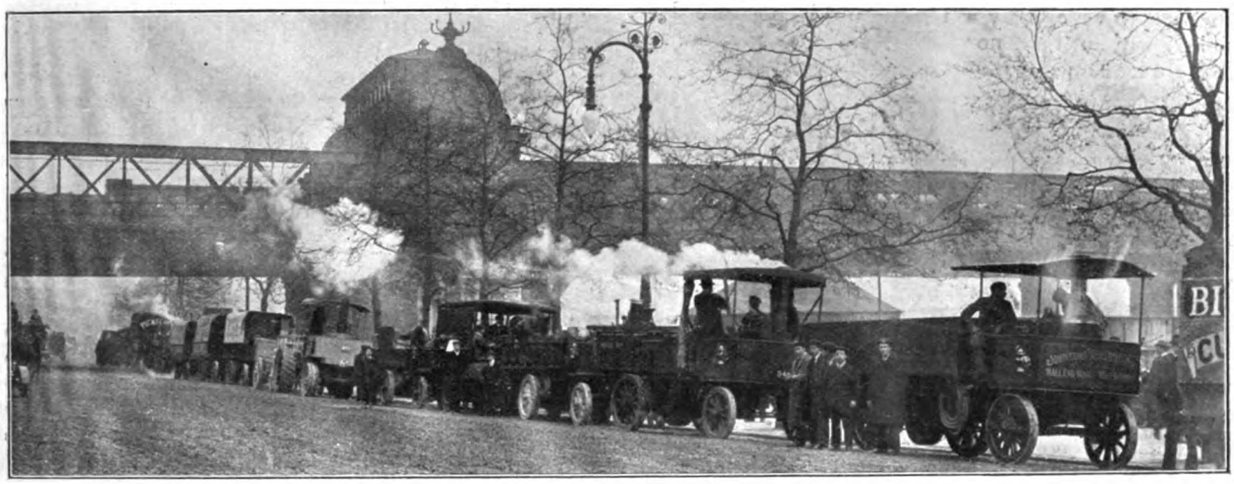

Photo by The Scene on the Embankment. [*Argent Archer.*

The three City of Westminster vehicles were considered by the judges to be of a very high order of merit and would certainly have had the team prize if one had been awarded. The vehicles belonging to Messrs. Hamilton and Wild and Robbins were also considered worthy of special notice by the judges.

THE SIDE-SLIP TRIALS.

THE TESTS ON FRIDAY.

ANOTHER stage in the trials, after one or two cars, including the Butler and the Rourke, had made up their distances uneventfully by a special run on Tuesday (26th ult.) was reached on Friday, the 29th ult., when the eleven competitors remaining started out for Potter's Bar for the resiliency trials on a hill in the neighbourhood. Several stops were made on the journey for the purpose of transferring the judges, who accompanied the run, from one car to another, some confusion being caused by a few drivers, unfamiliar with the route, stopping for this purpose at Finchley Road under the impression that they had reached Finchley, where the change should have taken place. In spite of the generally dry roads, the hill just before Barnet was greasy as usual, and the device on our car proved a welcome and apparently effective safeguard, which was to receive a further practical test before we had finished our return journey.

Arriving at the hill, we found No. 3, a Wolseley, which had started half an hour before us, already there, while the Georges Richard, L'Empereur, and Parsons, No. 14, were close behind. The hill proved to be about 500 yards long, with a gradient we should guess to be about 1 in 20, and a gentle up grade of 1 in 30 or thereabout at its base. Down this hill the cars were sent, one at a time, with the engine out, the distance to which they would run up the opposite slope, both with and without their non-skid devices, being measured. Two trials were made under each condition, which, of course, in

The "Crown" Tyre Protector entered by Messrs. W. Jenkinson & Co. in the Side Slip Trials. The protector consists of narrow transverse strips of solid leather threaded on wires to form a complete cover to the tyre. The ends of the strips are joined to a common strap on each side, and the device is retained on the tyre by lacing under the rim. The strips of leather are so arranged as to present a rough surface on the tread.

the case of fixed treads involved changing the covers, while occasional interruptions caused by the passage of leisurely country carts—and cows—further prolonged the proceedings. At this stage the majority of those concerned began to realise the wisdom of the minority who had provided themselves with needful provender, and hasty automobile reconnaissances were made along the road in both directions, one car returning after a short absence with the news that they could get nothing but plum cakes, and producing a large consignment of the same in evidence. These, however, were better than nothing, and served until the other car, which had ventured further afield, came back with a mixed cargo of sandwiches, whisky and ginger beer, little of which accompanied it in its further journey to the top of the hill. With the advent of provisions, however, the weather changed, and continued showery during the rest of the afternoon, though not enough to greatly affect the road surface before the trials concluded.

The following figures, being in most cases the average on the four runs of each car, though unofficial, will give some idea of the various performances.

No. 1. Butler, 15-h.p. Panhard, ran 13 ft. 8 in. further without the device than with it. First two runs only.
No. 2. Cavendish, 10-h.p. Panhard, averaged 34 ft. further without device.
No. 3. Hunt. Wolseley, averaged 43 ft. further without.
No. 5. Rourke, Pipe, did 142 ft. further without. First two runs.
No. 6. Nicholson, Star, did 80 ft. further with the device than without: apparently method of withdrawing it exercised a certain braking action.
No. 7. Vivian, Benz, did 35 ft. further with device. First two runs.
No. 8. Wilkinson, Wolseley, did 14 ft. further with than without First two runs.
No. 11. Sainsbury, Argyll, 36 ft. further with device. First two runs.
No. 12. L'Empereur, 86 ft. further without than with device. First two runs.
No. 14. Parsons, averaged 59 ft. further without device.
No. 15. Billet, averaged 121 ft. further without device.

Comparisons on this point will be brought out by the actual skidding tests, the date for which is as yet uncertain. The difference between the furthest and the least distance run by any of the cars was 520 feet, and in some cases the difference between two runs of the same car under similar conditions was greater than any variation caused by the device; the fact, however, that the road was slightly damped by a shower before the trials were over may have had some influence on the results. With regard to the motor-bicycles, some of the devices, as the Wilkinson and Parsons, seemed to have little effect, while others, as the very ingenious Empire, which consisted of two legs with castors, on springs, and retractible by back-pedalling, had, as might be expected, a considerable retarding action. This, however, would be of minor importance in a device only dropped when required.

The trials concluded soon after 4 p.m., rain falling fast before the return journey was finished, and making the roads, as town was approached, rather treacherous. This, however, gave an opportunity of observing the use of the devices not to be despised, and we understand from the passengers on the various cars that most of them were more or less effective.

QUIET RUNNING.

IN the not very far distant future quiet running will be an indispensable attribute of a high-class petrol car. Lacking it, a vehicle efficient in other respects will prove slow of sale, critical buyers refusing to be cajoled into purchasing it. The feature is one which now marks many high-grade productions, in which engine design and construction have been carried to a stage closely approaching perfection. By the use of lavish generosity in the matter of power, thus providing a reserve for bad roads and steep hills, which obviates any necessity for overworking the engine, makers are able to show results which stamp their cars as a distinctly superior product. Buyers recognize the fact that in these cars the engine always, or nearly always, runs at a normal rate, the reserve power being sufficient to cope with any emergencies which may arise.

Not very long ago all petrol cars were noisy. Their appearance was heralded by a din, in which the throb of the exhaust vied with the rattle of transmission gear for pre-eminence. When abnormal conditions prevailed, when the going was heavy and the engine was called on to do its utmost, the hub-bub became greater, until it seemed as if the limit of endurance and performance had been reached. All that is being changed. Every maker's aim is to provide his car with sufficient power to cope with emergencies without having to call upon the full capacity of the engine. The measure of his success depends, in a way, upon the power carried in reserve. If the tractive resistance, say, on a steep hill, increases 50 or 100 per cent., as it frequently does, the motorist does not want to cut down his speed correspondingly; consequently, he calls on his reserve power and takes the hill at a speed little, if any, slower than that at which he had been going along the level.

In other words, the desideratum with the petrol car is greater flexibility, just as this is the feature which most commends the steam car. Greater power means greater flexibility, for with it the driver is measurably free of limitations imposed by the necessity of changing speeds every time the character of the road changes. A little extra horsepower is like a corps held in reserve, which can be called on in time of need and made to pluck success from apparent failure.

The Paris-Bordeaux-Paris Motor-Bicycle Reliability Trial—The Scene at the Finishing Point.

CONTINENTAL NOTES.

Hill-Climbing at Perigueux.

A hill-climbing competition is to be held on the 15th inst. over a kilometre course at Perigueux. The contest will be open to (1) motor-bicycles under 50 kilog.; (2) motor cycles weighing 50 kilog. and over; (3) voiturettes under 400 kilog.; (4) light cars between 400 and 650 kilog.; (5) cars between 650 and 1,000 kilog.; and (6) cars over 1,000 kilog. As we go to press we learn that the Prefet of the Department has refused to sanction the contest.

◆ ◆ ◆

Motor-Boating from Rouen to Havre.

A motor-boat race is to be held on the Seine from Rouen to Havre on the 10th and 11th July next for the "Coupe de Rouen." A large number of entries has, it is stated, been received.

◆ ◆ ◆

The Calais-Dover Motor-Boat Race.

The Automobile Yachting Committee of the A.C.F. has fixed Calais as the starting point of the motor-boat race to Dover on the 8th August next. The event is international, and will be open to steam and electric launches as well as to boats fitted with petrol, alcohol, or petroleum motors. An exhibition of the competing boats is to be held in one of the docks at Calais on the 7th August.

◆ ◆ ◆

The Belgian National Circuit.

Le Circuit National Belge is to start on the 31st inst. from Brussels, Antwerp, Liege, and Spa being visited. At the last-named place it is probable that a new competition will be inaugurated—to test which car can run the slowest over a kilometre course with the engine throttled down to its minimum speed.

◆ ◆ ◆

The Italian Motor-Cycle Reliability Trial.

So far twenty-seven entries have been received for the 1,000 kilometre reliability trial for motor-cycles, which is being organized by the "Gazette dello Sport," of Milan, for June 12th next. The entries comprise the leading Italian, German, French and Austrian machines, English motor-cycles being still noticeable by their absence from these Continental competitions.

◆ ◆ ◆

A Tyre Test.

M. L. Bourcier Saint Chraffrey, who was identified with the recent anti-skid trial from Paris to Nice and back, is now organising a pneumatic tyre test from the point of view of traction effort. It is to be held on the 27th inst., on the macadamised National road on the right bank of the Seine, starting from Neuilly. The different tyres entered are to be tried on an electrical car (rear wheels 1,020 by 120) and the weight on the back tyres will be fixed at 1,000 kilog. The trial will be divided into two classes: (1) smooth tyres, and (2) tyres fitted with anti-skidding bands, and these will be tested under pressure of 6, 5 and 4 kilogs. per square centimetre.

Automobiles in France.

According to a return of the French Administration des Finances, there were 19,886 motor-cars in use in France at the end of 1903, as against only 7,260 in 1902 and 1,672 in 1899. The largest number of cars is in the Department of the Seine, which is responsible for 4,570 of the total, Seine-et-Oise coming next with 1,146. Of motor-cycles there were, according to the return, no less than 19,816 in use, of which 4,264 are in the Seine Department.

◆ ◆ ◆

The Paris-Bordeaux-Nice Motor-Bicycle Reliability Trial.

The reliability trial for motor-bicycles organised by the Autocycle Club de France was concluded last week, and the report of the judges is now eagerly awaited. Out of the twenty-eight competitors who left Bordeaux on the 25th inst., twenty-two reached Paris safely on the evening of the following day. As was mentioned last week, fifty-nine riders actually started in the event, so that over 50 per cent. failed to get through.

◆ ◆ ◆

Racing at Frankfort-am-Main.

In connection with the Gordon Bennett week the Frankfort Automobile Club is organising a motor race meeting to be held on the trotting track in Frankfort-am-Main on June 19th. There will be seven events, including a consumption test.

MAY 18th has been agreed to by the Local Government Board as the last day on which objections to the speed limit proposed by the Newport (Mon.) Town Council, in Commercial Street, High Street, Clarence Place, and across Newport Bridge, can be lodged.

CORNWALL is said to be full of visitors, and the Great Western Railway Company will run, on and from Monday, an augmented service of motor-cars between Helston Station, Mullion, and the Lizard, to promote the pleasure of excursionists in this district.

MESSRS. NYE AND COMPANY, LIMITED, have been registered with a capital of £5,000, to acquire the business carried on at the Regency Mews, Brighton, and to carry on the business of jobmasters, livery-stable keepers, repairers and proprietors of motor-cars, etc.

THE Pioneer Automobile Company, of San Francisco, has recently increased its capitalisation to 200,000 dollars, and has purchased the land on which the new building is situated. The company has also purchased the business of the Oldsmobile Company of Southern California, which embraces Los Angeles and all surrounding territory.

THE HIGH-TENSION IGNITION SYSTEM FOR PETROL MOTOR-CARS.

By J. W. Frings.

(*Continued from page* 194).

THIS secondary winding it will be seen is thus entirely distinct from the primary coil, and forms, through the high tension (thickly insulated) wire to the centre wire of the plug, and back through the body of the latter, the engine and frame of the vehicle, to the coil again, a complete circuit, broken only at the spark gap. Here, owing to its high potential (some thousands of volts) the discharge is enabled to bridge the gap through the air—a very different conducting medium, with inconceivably rapid alternations at the moment that the trembler on the contact breaker, or the armature on the coil, as the case may be, is making and breaking contact.

The "return" for the secondary circuit was, in the older type of coils, made through the external bands of brass seen on the De Dion coils, one of which was connected to the other end of the secondary wiring by a screw passing through the vulcanite casing; the brass bands themselves being pressed into more or less intimate contact with the frame of the vehicle by the metal

A White Steam Car in a Cypress Forest in California.

clips supporting the coil. With the later type of coils, in connection with which the frame of the vehicle is usually employed for a part of the "return" for the primary circuit, this idea is utilised to provide for the more efficient "return" of the secondary circuit also, by connecting—inside the coil—the secondary and primary windings together at one terminal, so that the wire from frame to coil answers the twofold purpose of conducting both the primary and secondary to that point.

There is a very useful electrical formula which runs $C = \frac{E}{R}$, which means that the current which passes is the quotient of the voltage divided by the ohms (resistance). Most coils are wound to give a resistance which passes half an ampere with a pressure of four volts, the resistance in this case being 8 ohms. From this it will be evident that to connect two accumulators in series, giving a pressure of 8 volts, as is sometimes done, would allow to pass double the current that the coil is intended to work with, and might possibly "burn it out" by breaking down the insulation. In this connection it will be well to make clear a point that is to most lay minds a particularly obscure one. The voltage of all cells, whatever their size may be, is always the same for similar couples or elements. Taking an accumulator as an example, the voltage of an accumulator of such a size that it might comfortably be accommodated in the waistcoat pocket would be the same as that of one with fifty times its plate area. The voltage is increased only by coupling in "series," *i.e.*, by presenting a continuous path of alternate elements, the voltage rising with each fresh addition to the chain by the amount of the voltage of the additional cell. On the other hand, the amount of current that a cell will "take" and "give" is proportionate to its plate area; the larger the cell the greater its capacity for holding and surrendering a charge. Thus, coupling two accumulators in parallel will not injuriously affect the working of the coil, but will extend the quantity of electricity which the battery will give to the sum of the ampere hours of both, and will therefore double the time during which the coil may be worked.

The Condenser.—This, as has been indicated in the definitions, has a most important function to perform. When a current is allowed to circulate, when a circuit is closed, a momentary induced E. M. F. is "created" in the circuit of the primary winding, which tends to retard the growth of the current. On the other hand, at the moment of breaking the circuit a momentary E. M. F. is induced which tends to maintain the current flow, and thus to produce excessive sparking at the contact breaker. It is then that the action of the condenser is seen. The latter is connected in the primary circuit as a shunt, or alternative path and reservoir, into which the momentarily induced current passes when the circuit is broken. This charge is given out when the circuit is closed again by the contact breaker, and thus the condenser helps the primary current at "make" and prevents sparking at "break," besides increasing the E. M. F. induced in the secondary coil. The capacity of the condenser for temporarily "holding" the charge and parting readily with it again is dependent primarily upon its area—size and number of sheets—and the efficiency of its insulation and perfection of its contacts with the primary windings. Inattention to either of these points in construction will result in wasteful expenditure of current from the accumulator, excessive sparking at the contact breaker and consequent pitting or burning of the contact points, and lastly, the most important defect of all, the induced E. M. F. in the secondary windings will fail to provide a discharge at the spark gap of sufficient intensity to fire the compressed gases. The condenser is usually to be found, in the cylindrically-shaped coils, wound around the body of the coil, outside the secondary windings, which are well insulated from it by a thick coating of a vitreous material—wax or shellac, etc. The complete coil is then slipped into its vulcanite case. Some coils allow for the withdrawal of the primary windings and core from the centre in a solid mass, and this, though a much more expensive form of construction, is greatly to be preferred to that in use with the cheaper types, where the secondary wire is wound upon the same bobbin, and is inseparable from it, except by unwinding layer by layer.

Coil Terminals.—In the older types of coil five and even six terminals were to be found—two for the primary circuit two for the condenser, and one or two for the secondary. By internal connections in the coil it is possible to do with but three, and this is the arrangement now usually adopted, even when the added complication of a trembler, or vibratory armature, on the coil itself is present. The connections for the three terminals should be fairly obvious, after what has been said. The two found at one end of the coil are the ends of the primary winding, to each of which is connected one end of the condenser. The single terminal found at the other end of the coil is for the high-tension (thickly insulated) "lead" to the sparking plug, the "return" in this case being through the engine and then *via* the primary "return"—which is also partially a so-called "earth," the frame of the vehicle—and thence, by internal connection, to its own terminal.

(*To be continued.*)

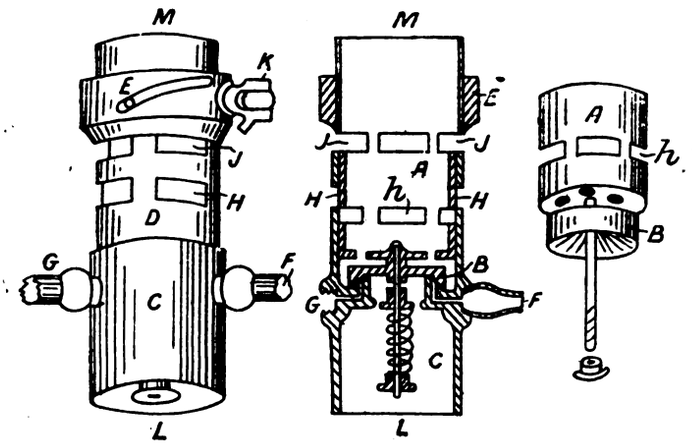
SOME USEFUL NOTES.

THE arrival of a new car is generally a long-expected and, too frequently, long-delayed event, occasioning a thrill of excitement in the bosom of even the veteran motorist, which with the tyro is often accompanied by an amount of anxiety regarding the new-comer's constitution and treatment, not inaptly comparable with that of a mother on the advent of her "first."

IT is unlikely in these days than an absolute novice will receive his car without the opportunity for practical instruction of some sort, as some of us did in the early days of the movement, and this should be followed—if not, as it should be, accompanied—by a careful study of the use and function of every part of the mechanism. Where the owner is already familiar with some other type of car, special note should be taken of any important differences in the driving arrangements, as the general tendency to more or less uniformity in these makes small discrepancies more puzzling. Some that may be noted as existing in popular types are: reversal of brake and clutch pedals, so that the latter is actuated by the right foot; reversal of order of speeds; ditto of direction of the action of the accelerator, or of the throttle, while the introduction of the usual single lever for change speed and reverse has led to mistakes where the driver was habituated to a separate lever for reversing.

SPECIAL note should be taken of the position of every lubricator, grease-cup, and other oiling arrangements, remembering that each working part must be supplied with lubricant from somewhere. And here a caution may be advisable to those who, being used to ball-bearings, change to a car with plain ones, that the latter will not suffer neglect of lubrication as peaceably as the former.

AS regards a new car, the chief attention it requires is in this same matter of lubrication, which should be free and plentiful, with due consideration for the troubles induced by excessive supply to the cylinder. This usually causes rapid fouling of ignition points; but a new cylinder generally lets more oil past the piston at first than after a little running, so the supply should not be cut down too much from this symptom, unless persistent.



ALL important nuts and bolts should be scrutinised for looseness after a run, especially those supporting detached parts of the mechanism, such as the silencer, carburettor, piping, pump, &c., not of course omitting those of the steering and brakes. It is not always superfluous to verify the freedom of petrol, water, and lubricating oil pipes from obstructions, arising from dirt or waste left in the tanks, while we have known a car sent out with a stoppage in the radiator due to resin.

THE novice may find the following *resume* of operations useful in the starting of his car, it being impossible, of course, to include variations necessary with some types. First, fill the petrol tank, using a funnel with a strainer. Next, fill water tank and see that the tap at the bottom of the water system is closed. Fill all grease-boxes, if present, see that axle-boxes are lubricated, and that the gear-box is plentifully supplied with lubricant. For this a thin grease, or mixture of grease and oil, is best; if too thick the gear wheels cut a track in it without oiling themselves. The addition of a few ounces of good graphite is beneficial in most cases. Fill all drip or other lubricators with a good motor oil, not too thick to travel along the pipes, and see that the crank-case of the motor has its charge of the same, and that the steering-pivots and chains are also attended to. Turn on and adjust lubricators. Put on brake, and see that change-speed lever is in out-of-gear position. Also that tyres are pumped up hard. Turn starting handle to see that compression is good, then open petrol tap, switch on current, and start motor, adjusting mixture if necessary. In case of failure to start, see if petrol reaches the carburettor; if so, whether the inlet valve sticks; then seek for cause of failure in ignition. Do not try to start with the petrol tap, throttle, or the switch turned off; it has often been attempted, but seldom succeeds. Drop in your clutch—or its representative—gently, and try the brakes in the same manner.

THE "ECONOMIC" CARBURETTOR.

UNDER the name "Economic" Mr. James Gibson, of the Economic Electro Plating Company, of Edinburgh, has recently introduced a new carburettor, of which detailed illustrations are given herewith.

The device has a suction valve B similar to an ordinary inlet valve, which when raised opens the spraying hole for the liquid. Air is at the same time drawn in, a small vane being provided in the passage to give the mixture a circular movement.

Details of "Economic" Carburettor.

A Inner tube, with slots H.
B Valve controlling petrol and water inlets
C Bottom casing of carburettor.
D Top casing of carburettor.
E Band for regulating opening of slots J.
H Extra air inlet to mixture.
J Slots for admitting air into cylinder before mixture is taken in.
L Air inlet to Carburettor.
M Mixture outlet.

On the top of the valve is fixed a short tube open at both ends, and in which a series of slots *h* are pierced at one level. This tube is surrounded by an outer tube, in which similar slots H are made, the latter being, however, at such a level that when the valve B is on its seat no air can pass through. The moment the valve begins to lift, the holes *h* are opened, and the higher the speed of the engine the higher the lift, and consequently the more pure air drawn through these holes. The strength of the valve spring is so proportioned as to allow more air to enter at the high speeds in order to compensate for the richer mixture drawn in. This enables the engine to be furnished with the best mixture at all speeds, resulting, it is claimed, in the development of greater power and less heating of the cylinder. Another circular row of slots is cut in the outer tube at such a level that when the valve is on its seat the holes are completely open, allowing free access of air to the inside of the carburettor; the bottom of the slots coincide with the top of the inner tube, fixed so that as the valve lifts the holes are closed. A band E is placed round the outer tube, so fixed that it can be moved by hand or by the governor of the engine, so that the holes may be given any degree of opening, from full open to closed. The object of this arrangement is to do away with the usual throttle valve, the speed of the motor being controlled by the admission of more or less air through the holes J. The advantages claimed for this method of motor speed regulation over throttling the charge are much greater economy—compression being the same as when full power and speed are wanted—and the fact that the cylinder is kept much cooler. A small inlet similar to the one for supplying petrol, controlled by carburettor valve, is provided at G for introducing water into the cylinder. Mr. Gibson informs us that experiments have proved that in introducing a moderate amount of water after the engine has started an increase of power is obtained, and that the cylinder is kept considerably cooler.

MOTOR-CYCLING NEWS.

SINCE we illustrated the "Rexette" in our issue of the 16th ult., the Rex Motor Manufacturing Company, Limited, have brought out an improved model, of which an illustration is given herewith. Its chief characteristics are a 5-h.p. water-cooled engine, two speeds, single chain transmission, a miniature car body in the place of the rear bucket seat on the old machine, and

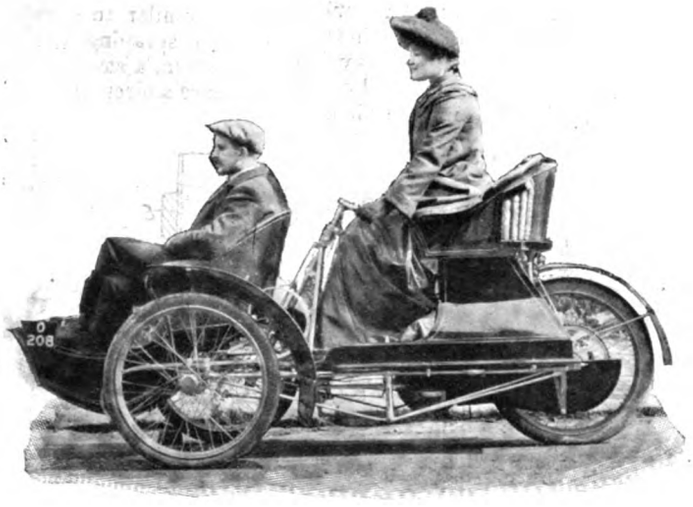

Fig. 1.—General View of the 5-h.p. Rexette.

a coach-built fore-carriage for a second passenger. The water-cooling is on the thermo-siphon system, a radiator being fitted behind the rear seat. The frame is of tubular construction, in which the motor is carried further back than in the old Rexette; it is concealed by an aluminium panelled body, having its base attached to a platform, carried by the frame. The speed gear box is enclosed in an extension of the engine crank case, and contains two spur wheels, A B mounted on the crank shaft F and continually in mesh with two pinions C D on the upper shaft G, the power being transmitted through one or other of the two pairs by jaw clutches, and thence through the friction

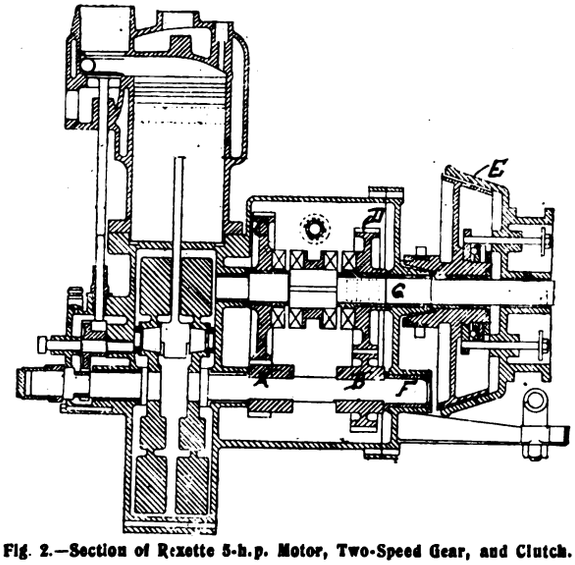

Fig. 2.—Section of Rexette 5-h.p. Motor, Two-Speed Gear, and Clutch.

Clutch E, and single chain drive to the rear wheel. We are informed that the new miniature car has been thoroughly tested and proved itself an excellent hill-climber.

◆ ◆ ◆

THE Motor Cycling Club is taking a plebiscite among its members on the following points. 1. What brake horse power do you recommend for a single-geared touring solo mount? 2. What form of transmission (give details, *e.g.*, 7-8 inch belt, spring sprocket, etc.) do you recommend to be used with the above? 3. Have you personally given the above combination an exhaustive trial? If so, on what make of machine?

◆ ◆ ◆

IN connection with the London to Edinburgh motor-cycle run, Mr. J. van Hooydonk will to-day (Saturday), take a party over the first portion of the route, viz., to Grantham. This part of the run will be performed mostly in the dark on the morning of the event, and as the road abounds with turnings, it is advisable for every competitor who possibly can to join in this preliminary trip, for the risk of losing the way in the dark is very great. A start will be made from the "Old Salisbury," Barnet, at 3 p.m., sleeping at Grantham, and returning to town on Sunday.

◆ ◆ ◆

ON Sunday Mr. E. Kennard, as Vice-President of the Motor-Cycling Club, entertained between 30 and 40 motor-cyclists at his hunting box in Leicestershire. When we consider that there were members who rode from distances as far apart as London and Liverpool, returning the same night, it speaks much for the reliability that has been attained by the lightest products of the new locomotion. In returning thanks for his health, which had been proposed by Riding Capt. Jackson, Mr. Kennard said in his motor house, mounted on his Napier, was a "Palmer" cord tyre which had run 500 miles without the slightest scratch or mark on it; that was proof of its powers of endurance. Mrs. Kennard, the well-known authoress, in a humorous speech, returned thanks for the way in which the toast of her health had been proposed. In brilliant weather, the return journey was commenced about 3 p.m, and we doubt not all safely "fetched up" at their respective destinations.

◆ ◆ ◆

HEREWITH we illustrate a new mechanical chain belt for motor-bicycles which has just been introduced by Messrs. Perry and Company, Limited, of Birmingham. The chain belt is, as

will be seen, constructed of steel links and leather pads. The leather pads are bound together by end plates, while the links are very flexible. The chain belt, which runs on standard pulleys, is claimed to be non-stretching and to be capable of being run loosely on the smallest pulley without fear of slipping, thus allowing the engine to develop its full power. It is also said to be unaffected by grease.

◆ ◆ ◆

THE annual meeting of the Motor Cycle Union of Ireland was held in Dublin on Friday last week. Mr. W. R. M'Taggart presided over a fair attendance of members, and the reports of the hon. secretary and the hon. treasurer were presented and adopted. The election of officers resulted as follows:—President, Mr. W. R. M'Taggart; vice-presidents, Messrs. J. B. Dunlop, sen., R. J. Mecredy, Hampden Shaw, and J. C. Percy; hon. secretary, Mr. C. G. Grey, 15, Marlborough Road, Dublin.

◆ ◆ ◆

A HUNDRED MILES reliability trial is to be held to-day (Saturday) by the Southern Motor Club. The maximum speed is to be 17 miles per hour, the route being from Purley to Nutley, *via* Caterham, Godstone, East Grinstead. Competitors will meet at Purley at one o'clock, and have their machines examined, the following parts being sealed by three judges:—(1) tool bag, (2) doors to tank, (3) make and break or wipe contact case, (4) pump, (5) float chamber. The start will be made at 1.30 p.m. prompt.

◆ ◆ ◆

THERE is nothing in the construction of a motor-cycle which cannot be readily comprehended, but a knowledge should be acquired before attempting a prolonged journey away from skilled help. As a rule, when one has acquired a knowledge of the functions of the various parts, and the mode of operation, a remedy will suggest itself should anything become temporarily deranged or fail to work in its normal manner.

HERE AND THERE.

THE headquarters of the Wolseley cars during the Eliminating Tests will be the Falcon Hotel, Douglas.

THE Hon. Charles Weld-Forester has ordered a 15-h.p. British-built Duryea car with side-entrance tonneau body.

MESSRS. S. BOWLEY AND SON notify us that they have reduced the price of their motor spirit one penny per gallon.

The 6-Cylinder 30-h.p. Napier, built to the order of Mr. Ernest Owers, a well-known member of the A.C.G.B.I. The body is rather different from that usually seen, and has been built to Mr. Owers' own design. The front is of the cabrio et type, and the back portion spreads gradually upwards and outwards, somewhat in the form of a tulip.

THE Scottish Motor Garages Company, Limited, have entered a 8-10-h.p. 2-cycle Vulcan car for the Glasgow-London run. It will be No. 31.

THE Northern Motor Company, of Belfast, have removed to 38, Chichester Street, where they have fitted up a well-equipped garage.

A MOTOR water cart has made its appearance in the streets of Folkestone, having been purchased by the Corporation for municipal purposes.

BY an amendment to the constitution of the Automobile Club of America the membership limit has been raised from four hundred to five hundred.

THE Albany Manufacturing Company, Limited, of Willesden Junction, have established a showroom and repairing depot at 93 and 94, Long Acre, W.C.

ON Sunday last a 12-h.p. Lanchester car succeeded in climbing the Great Orme's Head at Llandudno, thus repeating Mr. G. Higginbotham's recent performance on his 60-h.p. Mercedes.

AN international exhibition of sports is to be held at Scheveningen, Holland, from the 15th June to the 30th September next. The show will include a section devoted to automobiles.

ON Saturday last the Manchester Automobile Club had a week end run to Leasowe, which is situated on the Wirral Peninsula, making the Leasowe Castle Hydro their headquarters.

TWO 12-h.p. De Dion omnibuses, capable of seating eleven passengers each, and intended for a public service between Copenhagen and l'Amaque, have just arrived in the Danish capital.

MOTORISTS passing through Lichfield should give a call at Messrs. Jones and Company, of Talbot House, who have issued a handy road map of the district, together with a table of distances from Lichfield.

MESSRS. MACRAE AND DICK have added a department for the sale, hire, and repair of motor-cars in connection with their establishment in Inverness. They have also been appointed district agents for the Gladiator and Napier cars.

THE United Motor Industries, Limited, inform us that the Napier car which was lately driven 2,000 miles throughout England and Scotland was lubricated with their "D" oil, and that the "Castle" accumulators only were used on the car.

A SIX months' prospecting trip for precious metals by motor-car was begun in March by Messrs. Kelly and Smith McKay, who left Denver with a regular camping outfit and provisions for a tour in Colorado, Arizona and New Mexico.

THE U.S. Consul General at Cairo, in a recent report, states that the large agriculturists in Egypt are turning their attention to steam ploughs, and to any form of agricultural implement that can be used without cattle, and "are looking with much interest toward machines which are of the automobile type."

IN estimating the serviceability or probable life of any motor-car, the personal equation must be taken into account, just as it is in estimating the wearing qualities of apparel and other personal effects. A car will give one man good service for several years, while another might knock it to pieces in a month or two.

THE Massachusetts Automobile Club held a hill-climbing competition in Boston on the 19th ult. on a course one-fifth of a mile long on the Commonwealth Hill. Mr. H. P. Bowden, on a 60-h.p. Mercedes, and Mr. H. P. Hills, on a 40-h.p. Georges Richard, tied with 15 2-5 secs. for the first place. Mr. F. M. Marriott on a 6-h.p. Stanley steam car was second in 16 2-5 secs.

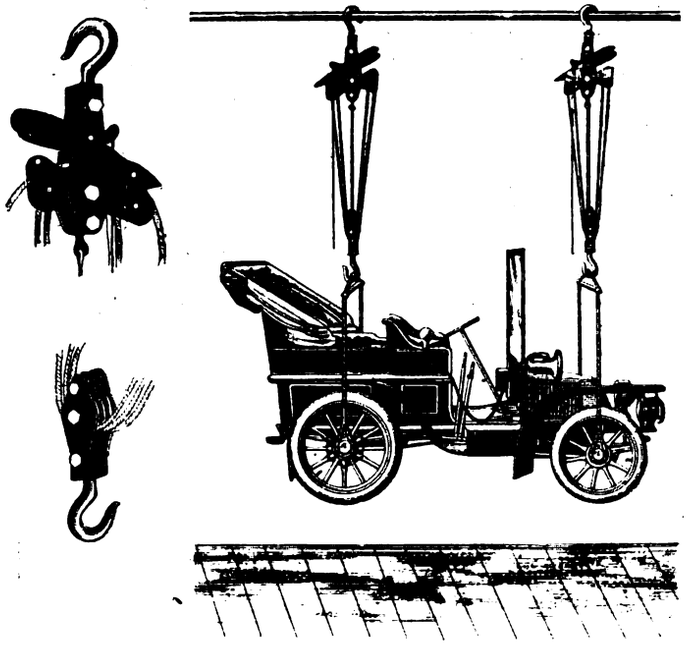
AT a meeting of the American National Association of Automobile Manufacturers, a resolution moved by Mr. R. D. Chapin, of the Olds Motor Works, opposing the Bill at present before the U.S. Congress, compelling the adoption of the metric system, was passed. The ground of objection was that a change in system would necessitate a complete upsetting of present standards, entailing great expense in new machinery and parts.

THE Wolseley Tool and Motor Car Company have sent us a photograph of one their 10-h.p. cars, which, when travelling at a good speed, side-slipped and charged a wall. The only damage suffered was that the front part of the frame and the radiators were pressed inwards for about five inches. The steering wheel was also bent, otherwise the car was quite uninjured, and, after a local smith had straightened the wheel, was able to continue on its journey. Even the damaged radiators were staunch, and on the day after the accident the car ran a hundred miles, to the works at Birmingham, where it was put right. The Wolseley Company point out that the stepped system of radiators used on their cars permit of repairs being made in a case like this very economically. Their position, too, protects the vital parts of the engine in case of collision.

Photo by] A Motor-Car Accident near Seaford. (See page 210.) [Wynter.

A WEEK of automobile and motor-bicycle races has been arranged to take place during the present month in Buenos-Ayres, Argentine Republic. A special prize has been offered by the city council, and the aggregate value of the prizes is reported to be over £1,000. The local agents for the Panhard, Mercedes, Fiat, de Dietrich, Mors, Darracq, Renault, and de Dion cars, and the Griffon, Peugeot, Werner, Adler, Humber and Iris motor-bicycles, are reported to have entered for the events.

Digitized by Google

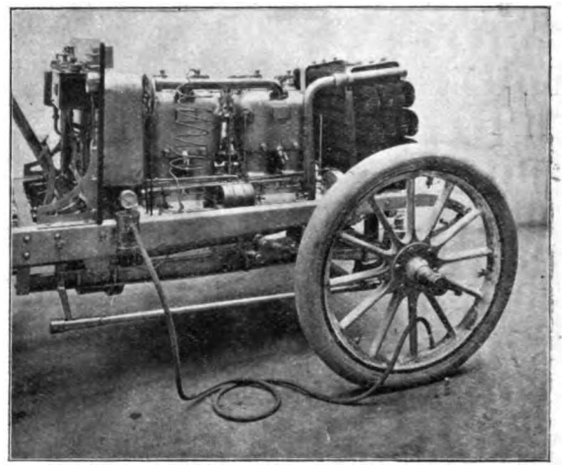


THE Swiss Automobile Club will hold a hill-climbing competition on Sunday next over a two kilometre course on the Cologny Hill, near Geneva.

ON Sunday last Baron de Caters made a number of attempts to establish a new record for the flying kilometre on his 90-h.p. Mercedes. The world's record stands at 23 3-5 sec., while de Caters' best was 24 2-5 sec.

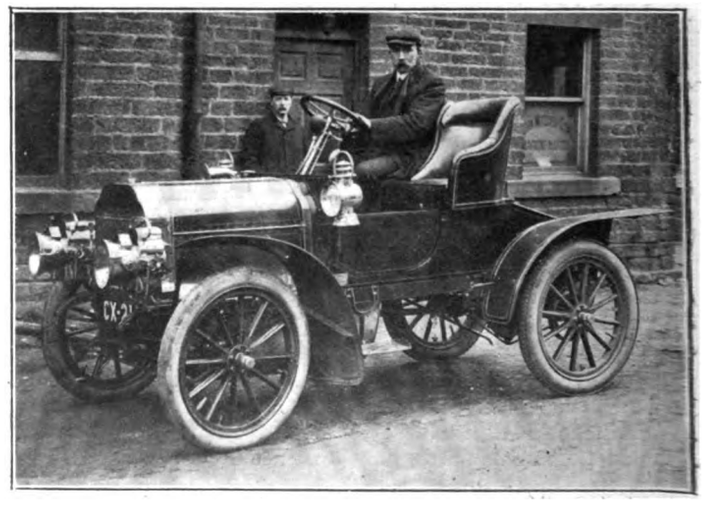
FROM the White Steam Car Company comes a copy of the fifth issue of their Bulletin, which, among other matters, contains an interesting account of a trip on a White steam car through the Adirondacks. The White Company will send a copy of the Bulletin to anyone interested.

A LIST of their motor accessories and fittings comes from Messrs. H. and E. Friedenhain, of 67 and 68, Bunhill Row, London, E.C. This is well arranged, and a complete index facilitates reference to the accumulators, carburettors, densimeters, inlet valves, jacks, pumps, radiators, tool bags, voltmeters, and a hundred other things which the firm are stocking for the use of motorists.



A FRENCH firm—Messrs. C. and E. Tourneur—has recently brought out a specially arranged pair of pulley blocks for lifting motor-cars off the ground, which should be found useful not only

by motor-car repairers, but by many motorists who have no inspection pit in connection with their motor house. The pulley blocks are of special construction, they being provided with a brake device, by means of which the car can be held at any desired height from the ground and let down gradually when desired. The accompanying sketches clearly illustrate the device, which is made in three sizes, to support cars weighing respectively up to 800 kilogs, 1,500 kilogs, and 3,500 kilogs.



MESSRS. H. M. HOBSON, LIMITED, inform us that Messrs. Peugeot Freres sold over 4,000 motor-cycles last year, and according to their present booking they, having already disposed of 2,000, will sell at least 6,000 this year. In addition to this, they have sold over 2,000 cycle engines. Messrs. Hobson are sole agents in this country for the Peugeot motor-bicycles.

MESSRS. C. JARROTT AND LETTS, LIMITED, have acquired a licence from Messrs. Turcat, Mery and Company of the rights to manufacture the automatic tyre inflater described in our issue of the 16th January last for the British market. The apparatus itself, which has been named the "Pompeesi," was illustrated in the issue referred to, while the accompanying picture shows it fitted to a car. The attachment is simple, a connection nut being screwed into the cylinder. If ordinary sparking plugs are used, it can be screwed into the same orifice as that in which one of the sparking plugs is attached, and the sparking plug could then be screwed in at an elbow-joint of the fitting; thus the

motor would not require any alteration when the pump was required to be used. The force of the explosion in the cylinder is then conveyed through a small curled steel tube to a metal box, which can be affixed on to the dashboard or on to the side of the car. The whole attachment can be made within three minutes, and, when once affixed, need never be taken off, as all that is necessary to pump up a tyre is to unscrew a small fly nut in the side of the metal box above mentioned, screw in the rubber connection, connect with the tyre, and then start the engine, and the tyre will be pumped up hard in three minutes. It is thus possible to make use of the engine in the car and so save the motorist the hard work entailed in pumping up tyres. We may add that the "Pompeesi" was awarded the Gold Medal at the trials organised by the Automobile Club de France in December last. The time taken in the trials for the inflation of the tyre was from 2 min. 45 sec. to 3 min. 30 sec.

THE accompanying illustration shows a new type of two-seated Argyll 10-12-h.p. car which has become very popular in the Huddersfield district owing to their great hill climbing power. The photograph was taken just after the car had completed a non-stop run from Glasgow to Huddersfield. Mr. C. Mitchell, who drove the car, left the Hozier Company's works at 8.50 on the morning of the 14th ult. and arrived in Huddersfield at 6.50 p.m. the same day, completing the journey of 230 miles within 10 hours. Mr. Mitchell reports that it rained nearly all the way, and that he used exactly 8 gallons of petrol for the run, which works out

at about 28½ miles per gallon. We may add that Messrs. J. Mitchell and Sons, the Huddersfield agents for the Argyll cars, have already this year taken orders for 18 of these vehicles.

CORRESPONDENCE.

LITTLE BIG CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—Why do the many varieties of small two-seated cars all lack the charm of the big car as regards noiselessness and springiness? Many a man of moderate means would keep a small car if it was built more on the lines of its big brother, or rather sister. Most of the small two-seaters are not only very noisy but badly sprung, and their little engines seem as if they were always trying to knock themselves to pieces. Why cannot we have a small car to weigh about 8 cwt., with say a three-cylinder engine, better luggage carrying facilities, and, by no means least, ability to travel slowly on top gear? Nothing is more tedious than the continual change of speed necessary on small cars, whenever the country is at all up and down. What is wanted is not great speed on the level so much as good average speed. Surely a small car ought to be able to average 20 to 25 miles smoothly and noiselessly like a big car without continual speed-changing.

The constant speed-changing and vibration is what knocks small cars to pieces and renders the cost of upkeep far in excess of what it should be in proportion to its original cost and size, besides being largely responsible for accidents due to parts shaking loose.

We have silenced the big car and got her to run almost anywhere on her top gear. Why not do ditto for the small car?—Your truly,

Silence is Golden.

BRITISH CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—I would like to add my testimony as to the value of our own native products. Three years ago I bought an M.M.C. car, although I was advised that there was not a decent English car on the market at the time. I thought last winter, that after all the miles I had travelled the engine and gear must require a thorough overhaul, but, on examination, the engineers to whom I sent the car stated that practically no signs of wear are apparent. (The largest part of their bill is for the inspection). The cost of upkeep has been exceedingly low and repairs have been practically nil. The car is very light on the tyres, and I presume this is due to good design and proper distribution of weight. The car is a good hill climber and has never failed me.—Yours truly,

W. Fountain.

DECAUVILLE CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—I run a 10-h.p. Decauville car, and shall be pleased to give Mr. J. W. Hicks my experience of it, if he will let me know the particular points on which he desires information. This car has proved satisfactory during the five or six months I have had it, but I have not run it a thousand miles yet owing to bad weather, absence from home, and other causes.—Yours truly,

W. A. Woodley.

To the Editor of *The Motor-Car Journal.*

Sir,—In answer to Mr. J. W. Hicks' enquiry *re* the 10-h.p. Decauville car, I think that I am in a position to express an opinion. Two years ago I was a passenger on the first of these cars, when, on May 17th, 1902, I ran to Bexhill, and on that day had the only involuntary stop, due to the engineering work, that I have experienced; this was the small matter of a pin shearing in a lever boss. I now possess my second Decauville car—a 10-h.p.—and have never had the least trouble with it. I drive every day in the traffic of London, and the car is always ready for a 200-mile run should I wish to do such.

In addition to my own two cars, I have had considerable experience with two others, a 10-h.p. and a 20-h.p., and have found the same excellent qualities of engineering work and design throughout.—Yours truly,

Robert W. A. Brewer, A.M.I.C.E., A.M.I.M.E.

To the Editor of *The Motor-Car Journal.*

Sir,—I have been driving a 10-h.p. Decauville constantly for the last fifteen months, and during the whole of that time I have had only two little mishaps with the engine. The first time there were suddenly a short series of pops, so that I thought at first the mixture was wrong. Examination showed that the cotter had come out of the inlet valve of one cylinder and the valve had dropped, but, fortunately, had caused no damage. I suppose I had forgotten to put in the pin in replacing the cotter after taking out the valve. However, with a piece of wire (nipped from a wire fence at hand) I made a temporary repair and got home. On another occasion I had the tap knocked off the front of the radiators through the careless driving of another motorist, who ran me too close in trying to cross at right angles. I managed to pull my car round in time, so that no further damage was done. I plugged the pipe with a bit of wood and was able to proceed to a repairer's, three miles away, to have the tap soldered on. With these two exceptions I have had no trouble at all, although I have driven the car some hundreds of miles. The engine is not one of those that require constant adjustment, and it pulls well uphill. I can certainly recommend Mr. Hicks to buy a 10-h.p. Decauville, for I think it is quite as reliable as the makers claim. The one thing I do not like about it is having the clutch and brake pedals coupled, but a driver can easily have this altered if, like myself, he believes in using his engine as a brake downhill.—Yours truly,

Licence No. 208.

To the Editor of *The Motor-Car Journal.*

Sir,—In reply to Mr. J. W. Hicks, I have been using a Decauville 10-h.p. car almost exclusively for twenty months, covering between 13,000 and 14,000 miles. Beyond a broken wheel due to side-slipping into a wall, the only replacements have been due to two broken carriage springs, heavy loads over rough roads, and a worn-out second speed, after about 9,000 or 10,000 miles, which had apparently been insufficiently hardened. I have had no trouble on the road with the car, except an occasional puncture or dirty plug to change, and even these have been few and far between. Car is very dustless, due probably to the clearance and encased flywheel. Average about legal limit in fairly hilly country, and have done at least 25 per cent. more on French roads. I could not desire a more reliable car, and the wear in bearings seems very small indeed. Car is about to have her first thorough overhaul since I had her.—Yours truly,

R. W. Buttemer.

A TOWCESTER WARNING.

To the Editor of *The Motor-Car Journal.*

Sir,—Last week my car, which is a 12-h.p. Talbot, was being driven from London, through Towcester, to Burton-on-Trent. On reaching a point two miles outside Towcester, my chauffeur saw a policeman and a man with a bicycle standing together talking; the policeman held up his hand, and my chauffeur immediately stopped the car in its own length. The policeman informed my chauffeur that he was driving at the rate of fifty miles an hour. His name and address were taken, and he informed us that the individual with the bicycle could give expert evidence. He was then allowed to proceed on his journey to Burton-on-Trent. In due course a summons arrived. Knowing my chauffeur to be an experienced and most careful driver, I took the trouble to engage the services of Mr. Staplee Firth, who found that the Bench interrupted during examination and cross-examination to such a degree that he had to talk gently but firmly to them, which so surprised and nonplussed these noble gentlemen that the case proceeded, and he obtained a fair and uninterrupted hearing. I should most strongly advise those who may find themselves in the vicinity of Towcester, which is not seventy miles from London, and are stopped by an extremely ponderous and well-developed policeman, who is invariably attended by an anæmic looking gentleman with black hair, who practises the role of expert witness, to obtain the services of some London lawyer who is as well acquainted with motor law as Mr. T. W. Staplee Firth, and I have no doubt that they will find that they have spent not only an extremely amusing and interesting day, but they will have the satisfaction of knowing that the money disbursed has been done so profitably, for on this occasion the result was instrumental in disposing of a similar case, which followed this one, in the defendant's favour. The chief constable being thoroughly disgusted, promptly withdrew a third case which was of a similar character.—Yours truly,

C. E

TYRES AND CARBURETTORS.

To the Editor of *The Motor-Car Journal.*

Sir,—In reply to "Mack Siccar," the shutter on the air inlet of the carburettor is not much use without being able to regulate the air lever whilst driving. With 12-h.p. there is great economy and heat reduction to be obtained. My Longuemare is about the same size, and I can make the mixture too weak with the air lever half open. Perhaps the carburettor is flooding or the air lever become disconnected inside; if not, then either the spray cone or the choke tube is to blame. The Longuemare shutter swings either way, I believe, but mine lies on the bottom of the air inlet when closed, and just able to clear the choke tube when open. I cut a piece of sheet copper as though making a joint packing to fit between the carburettor and air inlet pipe, leaving enough material at the top, when cutting out the centre, to make half the hinge. If this is not clear to "Mack Siccar" I would send a sketch if the courtesy of the Editor would permit him to send his address.

In changing gears down more knack is required than going up, and one has to wait, or use brake, till the car is travelling at the lower rate of speed.—Yours truly,

Thomas Hallewell.

CORROSION OF TERMINAL.

To the Editor of *The Motor-Car Journal.*

Sir,—For some time past I have had a great deal of trouble in keeping the positive terminal of the accumulator on my motor-bicycle free from corrosion; it very rapidly assumes a green colour, and on the inside a crystal formation is seen. I shall be greatly obliged for any hints how to prevent the corrosion.—Yours truly,

Tympanum.

[Corrosion of the terminals is caused by one of two actions. It may be the result of the action of acid upon the metal of the terminal, or it may be caused by electrolytic action from the passage of a very small

Digitized by Google

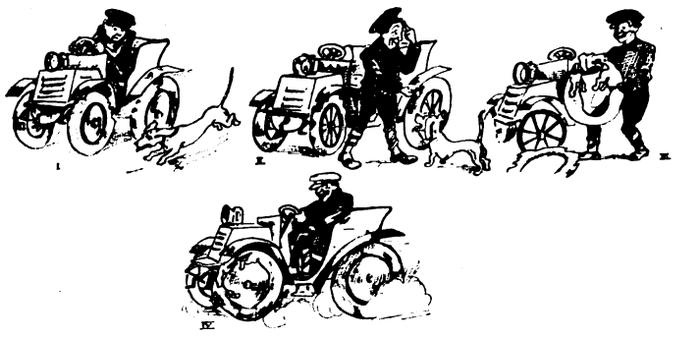
current of electricity between the two terminals. If caused by the first action it can be prevented by carefully cleaning the terminal with a weak solution of ammonia and water, and then with pure water. When quite clean cover the terminal with vaseline. If the corrosion arises from the second action it requires more care to entirely remove the trouble, and as "Tympanus" says that his positive terminal is the one giving trouble, electrolytic action is probably the cause. To prevent this, first clean the terminal in the same manner with ammonia and water, and cover it with vaseline. Also make a groove round the stem of the lead pillar on which the terminal is mounted, and fill this groove with vaseline. Then make certain that no passage of electric current is allowed to cross from one terminal to another by thoroughly drying the space between the two, and when quite dry put a dressing of vaseline on the surface between the terminals. To ensure success the old corrosive deposit should be entirely removed, clean very thoroughly with water after the ammonia, and anoint every part that is exposed with vaseline, except the surface on which the wires make contact.]

EMPLOYERS' VIEWS ON DRIVERS.

To the Editor of *The Motor-Car Journal*.

Sir,—A good deal has lately appeared in the press regarding motor-car drivers, or, to be more precise, I suppose I should say chauffeurs, and I should therefore like to take this opportunity of relating an experience which I trust may benefit those who are on the look-out for a competent man, and others who are over-anxious to leave their own particular calling to enter the motor industry, which, unfortunately, in most cases are accelerated by means of misleading advertisements. It was my lot some little time back to interview applicants in answer to an advertisement for a competent driver who was capable of doing all ordinary repairs, and it grieved me, when cross-questioning these young fellows, to think how they had been misguided, for in most cases they knew absolutely nothing of lathe work—in fact, the use of any tools whatsoever; of tube or magneto ignition they had never heard, and their knowledge generally on motoring matters could be described in no other way than woefully crude. The most serious part, to my mind, is that in most cases these young men possessed certificates wherein it told them they were quite proficient, and this innocently they appeared to believe. I also learnt in a great number of cases premiums, ranging from £5 and upwards, had been paid, and their total mechanical training had lasted from one to two months. Now I certainly think that something should be done to assist these misdirected persons, as the present system is tending to bring the whole trade into disrepute, for common sense tells us that a man should have had at least three years in a good workshop before he can even be termed useful.

I shall be pleased to hear the opinion of other owners on this subject. —Yours truly,



A. F. Setac.

To the Editor of *The Motor-Car Journal*.

Sir,—I have read the correspondence recently appearing with regard to motor-car drivers, etc., and, having just gone through an experience with a "thoroughly capable man," I should like to recount same for the benefit of your readers. I engaged a man who stated that he was thoroughly conversant with the Panhard car, and who furnished me with excellent testimonials, including one from a so-called "motor expert" in the trade. On his arrival I sent him out with one of my men for a trial, who, on their return, told me that he did not think him much good; but, being very reluctant to believe this, I sent him out for a further trial with my works manager. I was astounded to learn, on their return, that not only was the man incapable of driving even passably, but he was absolutely ignorant of the use of the reversing lever, the accelerator, or ignition lever. I, of course, dismissed him immediately.

Supposing this had been the case of a private owner, what might have occurred? The owner would doubtless have relied upon these testimonials he produced and engaged him—placing him in charge of a car worth, perhaps, hundreds of pounds. What would have been the result? Repairs, repairs, repairs, unsatisfactory running of the car, and another dissatisfied owner. This illustration shows how careful owners should be into whose hands they place their valuable cars if they wish to have satisfaction.—Yours truly,

Frank Morris.

THROTTLE GOVERNING.

To the Editor of *The Motor-Car Journal*.

Sir,—I should be glad of advice from any readers of the *Journal* with regard to a little trouble I am experiencing with the motor of my car. It is controlled by a governor working on a disc valve placed in the admission pipe. At present the running of the engine is extremely erratic, as the governor seems to come into action suddenly and cuts off the mixture from the motor, upon which, of course, it slows down and the valve is again opened. It has occurred to me that the governor needs adjusting. Perhaps someone who has experienced the same difficulty can give some useful information on the matter.—Yours truly,

J. L. Player.

QUERIES *re* PANHARD CAR.

To the Editor of *The Motor-Car Journal*.

Sir,—Can any of your readers enlighten me upon the following? I have just bought a new 7-h.p. Panhard. When driving same I get a knocking noise, which seems to come from the gear box. This noise appears on all four speeds and becomes worse if I use the accelerator, yet it immediately disappears if I slip the clutch a little, or if I am on a slight descent. Also what is the average mileage on a gallon of Pratt's petrol, and the best position to have the gas control when driving.—Yours truly,

7-h.p. Panhard.

THE VALUE OF A CERTIFICATE.

To the Editor of *The Motor-Car Journal*.

Sir,—Having followed the correspondence on drivers from the beginning of this controversy in your valuable journal, I am delighted to see at least one mechanic writing: a mechanic who knows his work will not write articles and ventilate his grievances in a newspaper. If he is certificated or not, a good worker always gets his price. "Mechanic" in your recent issue complains about the driving school certificated mechanic, but what does he know about them? Why doesn't he start a motor-driver union, and lay his complaint before the committee? They would be more capable of dealing with this question than the public in general is able to do. Besides, I think it is high time that such a society should be formed to look after the interest of the motor-car driver.—Yours truly,

Certificated.

ACETYLENE MOTORS.

To the Editor of *The Motor-Car Journal*.

Sir,—We hear less of acetylene now as a possible motor fuel than we did three or four years ago. At that time many experiments were being carried on both in Europe and the United States, with the object of utilizing it for power purposes; but the new agent was found very difficult to control. Motors of special construction would undoubtedly be necessary for acetylene, as the heat generated from its explosion is more intense than that produced by the combustion of the petrol mixture. This would necessitate additional complication, but I have entertained hopes that in time acetylene would prove a suitable fuel for vehicle motors, and have persistently scanned the current automobile literature for news of practical progress in this direction. Up to the present time, however, I have been unable to learn of any substantial evidence which could give stronger colour to that hope. Acetylene seems to be still much in futuro, while petrol as a motor fuel is a present fact.—Yours truly,

F. J. Spencer.

SPARKING PLUG POSITION.

To the Editor of *The Motor-Car Journal*.

Sir,—I have a four-cylinder motor in my car, all the valves of which are mechanically driven off a single cam shaft on one side of the motor. The sparking plugs are fitted horizontally in the sides of the valve chambers abreast of the inlet valves. Their position makes it inconvenient to get at some parts of the motor, and I have in mind changing them to the valve covers, which, of course, are immediately over the valves. I would very much like to know whether it is best to locate them over the inlet or the exhaust valves, and the reasons for the choice. —Yours truly,

Smithsonian.

[The best position for the sparking plugs, in the event of changing them from horizontal, would be over the inlet valves. The reason for this is, that there is always the possibility of some exhaust gases remaining in the locality of the exhaust valve which does not become mixed with the fresh incoming charge, and if the plug is placed over this firing is not so sharp as over the inlet valve, where the spark is in close contact with the incoming charge.]

Parchment for Joints.—A correspondent enquires for the names of firms supplying parchment for joints.

Terminal Connections.—Replying to C. H. Peake, the Herz terminals can be obtained from Messrs. Herz and Company, 55, Grand Street, New York.

Lost Glove.—A. E. writes that a fur-lined glove was dropped from a car travelling between Crawley and Handcross on Sunday last. Should any reader have picked it up, A.E. will be obliged by its being forwarded to our offices for transmission to the owner.

CLUBS AND ASSOCIATIONS.

SOUTH LINCOLNSHIRE.

AN enjoyable meet took place at Boston on Thursday of last week in connection with the South Lincolnshire Motor Club. Although threatening clouds were visible, the weather remained fine and the automobilists who attended from a distance had a pleasant run. The members met at the Red Lion Hotel, whence they proceeded to the ancient market-place, a parade being held in front of the Ingram monument. Pedestrians manifested much interest in the parade, a large crowd assembling. Subsequently the members returned to the Red Lion Hotel, where they partook of tea. The following is a list of the ladies and gentlemen who attended the meet:—Dr. and Mrs. Crompton, Benington, 5-h.p. Baby Peugeot. Mr. F. Dennis, Kirton, 5-h.p. Baby Peugeot. Mr. S. G. Lovell, Stickney, 5-h.p. Wolseley. Mr. H. C. Johnson, 8-h.p. Peugeot. Mr., Mrs. and Miss Linnell, Market Deeping, 12-h.p. Wolseley. Mr. and Mrs. A. H. Holland, motor-tricycle. Mr. C. Holland and Miss Holland, 9-h.p. Peugeot. Dr. Mason, 5-h.p. Baby Peugeot. Dr. Miller (captain), Mrs. Miller and Miss Saul, Wrangle, 4½-h.p. De Dion. Mr. and the Misses Pilley, 6½-h.p. Peugeot. Mr. F. Richardson (secretary), Sibsey, 10-h.p. Wolseley. Dr. South, 5-h.p. Baby Peugeot. Dr. Wrinch, Phœnix motor-bicycle. Mr. F. Saul, Wrangle, motor-bicycle.

The next meet of the club takes place on Saturday, May 14th, at Market Deeping, when the members will be entertained by Mr. and Mrs. Linnell. It is hoped that there will be a good muster on this occasion.

Parliamentary candidate for the Gainsborough division) for a meet at Riseholme Hall, on July 16th, was accepted. It was also decided to accept the invitation of Sir Charles Seely, M.P., for a meet at Sherwood on July 23rd or August 6th, whichever was most convenient to Sir Charles. It was stated that the Lincoln members of the club were desirous of entertaining their fellow-members at Lincoln, and August 13th was fixed for the event. Mr. J. D. Sanders' invitation to entertain the club during the last fortnight in September was accepted, and in connection with this meet Mr. Sandars will organise a hill-climb, near Gainsborough. The date to meet the Sheffield Club at Ollerton, in the Dukeries, was fixed for July 2nd, and the hill-climbing competition at Market Rasen in connection with Mr. A. A. Padley's invitation for June 16th. A sub-committee was appointed to meet the members of the South Lincolnshire A.C. at Boston on May 12th, to endeavour to arrange an amalgamation of the organizations. It was stated that a circular was being sent round to the club members pointing out the care they have always had for considera'e driving, and expressing a hope that they would continue to use the roads with due consideration for the convenience and rights of other vehiclists.

Tea was provided for the motorists and their friends at the hotel between four and five o'clock, and very shortly afterwards the cars left for their various destinations.

Among those present were Capt. J. A. Cole, J.P. (chairman); Mr. E. Cragg, M.D. (hon. sec.); Major Ruston, J.P.; Capt. H. E., Mrs. and Mrs. A. Newsum, Lincoln; Mr. and Mrs. C. W. and Mr. W. R. Pennell; Mr. G. Lowe, M.D., Lincoln; Mr. G. E. and Miss Sandars; and Miss Beckwith; Mr. C. J. E. Parker, J.P., Capt. Lyall, Major

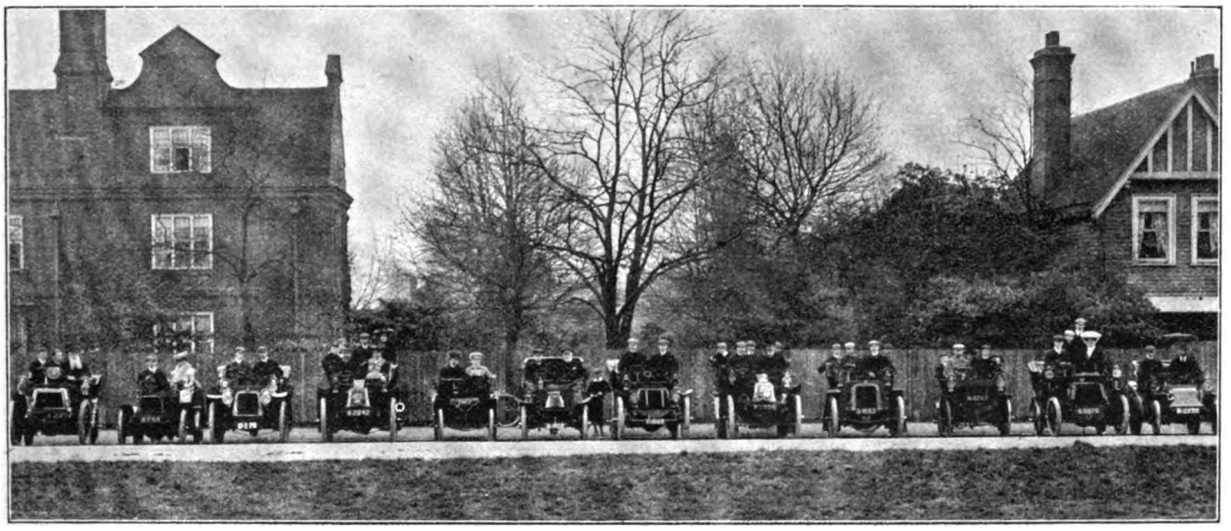

Photo by] The Meet of the Blackheath Automobile Club. (*See page* 209). *[E. P. Adams.*

LINCOLNSHIRE.

A DELIGHTFUL run in connection with this club was held last Saturday, when the members mustered in strong force at Brigg, a charming place with lovely scenery around it, on the edge of the wolds. It is a convenient centre for motorists, and those who attended the fixture were principally members residing in the northern part of the county. This was the third outing of the season, and fine weather again favoured the run. Some good hills (from which grand panoramic views were obtained) were encountered on the way, but they were not unsurmountable. The woods added considerably to the prettiness of the drive. Altogether, therefore, it was a very picturesque and enjoyable outing. The party made the Angel Hotel their headquarters, and much interest centred in the proceedings on account of the presence of some notable cars. For instance, Captain J. S. Ruston, of Lincoln, drove over on his 18-h.p. Mercedes, and Mr. J. D. Sandars, of North Sandsfield, and Mr. G. E. Sandars, of Scampton, each drove a Peugeot that won at the Southport speed trials last year, and which they afterwards acquired. Another interesting feature was a 20-h.p. Richardson, one of the highest powered cars, it is understood, the firm has yet introduced. Three 12-h.p. cars of the same make were also driven over by Lincoln motorists, viz., Captain Newsum, Mr. C. W. Pennell, and Mr. H. White. Captain J. A. Cole, J.P., of Roxholme Hall, brought the club's hon. sec., Dr. E. H. Cragg, of Pallingborough, on his 14-h.p. Durkopp, and other members were present from Gainsborough, Boston, Grantham, Market Rasen, and Sleaford, between twenty and thirty cars altogether putting in an appearance. The committee held a meeting after luncheon. Capt. Cole presided, and there was a representative attendance. The following were, briefly, the chief items of business which the meeting transacted. A sub-committee was formed to consider what steps could be taken with a view to assisting the movement for producing denatured alcohol for commercial purposes. The invitation of Mr. Algernon Moreing (the Goddard, Mr. J. W. Crooks, Mr. Lee, Mr. Meredith, Mr. G. W. Hanby, Mr. MacFarlane, Mr. Kiddell, Mr. C. Nelson (hon. solicitor), Rev. Wardle Hall, Mr. H. and Mr. T. W. Swaby, Mr. R. and Mr. W. Connell, Dr. Reckitt, Mr. J. D. and Miss Sandars, Mr. and Mrs. F. Jecock and Mr. P. E. Jecock, Mr. and Mrs. G. Garnett and Mr. Townsend, Dr. and Mrs. Sharp, Mr. H. and Mrs. G. Charlton-Jones Holton, Mr. Seagrave, Mr. and Mrs. C. H. Gilbert, Mr. N. Bell, and others.

HERTFORDSHIRE.

H.S.H. PRINCE LOUIS OF BATTENBERG has consented to become one of the vice-presidents of the Hertfordshire Automobile Club. The club held a successful run to Toddington, in Bedfordshire, on Saturday, April 30th. About twenty-five members and friends attended, the overcast condition of the sky keeping many away. The "Sow and Pigs" hostelry was the rendezvous, and after tea and chat the members strolled round the pretty gardens of the inn. A full programme of fixtures for the summer is being prepared by the committee.

WEST SURREY.

THE club were favoured with fine weather for their run on Saturday to meet the Reading A.C. at Odiham. Showers in the early afternoon had providentially laid the dust. Nine cars took part in the excursion carrying twenty-six members and friends, and the two clubs sat down to tea at the "George" some forty strong. The road *via* Farnham, though famous for its flints, which were loose and much in evidence, seems to have been responsible for only one puncture.

YORKSHIRE.

TO-DAY (Saturday), the Yorkshire Club is having a run to Cawthorne, where tea will be taken at the Spencer's Arms Hotel. On the 14th a visit will be paid to Bolton Woods, and a week-end tour is being arranged for Whitsuntide, with headquarters at the Bellsfield Hotel, Bowness.

LEICESTERSHIRE.

On Saturday the Leicestershire Automobile Club had a run to Daventry. Ten cars and two motor-bicycles started from the Bell Hotel at Leicester, and the route was *via* Blaby, Lutterworth and Rugby. The old town of Rugby was awakened from its usual state of somnolence as the cars passed through. It was market day, and things were quite lively. From Rugby to Daventry the road is a splendid one, level nearly throughout, and with a good surface. Daventry was reached well under two hours, and all of the cars came in without having sustained mishap. To the surprise of the members—and their pleasure also—the president of the club, Mr. G. E. Mawbey, was found awaiting them at the Wheatsheaf Hotel. He had travelled right through from Syston. Among those who took tea were Mr. and Mrs. Mawbey, Mr. T. C. King, Messrs. Hargreaves, O. Wright, Herbert, A. H. Faulkner, Clarkson, Barron, W. Clements, T. S. Pettifor, Whitby, G. H. Wait, Woodward, Bentley, Tyler, J. McAlpin, C. Langmore, Thompson, and Allan McAlpin (hon. secretary). A start on the return journey was made shortly after six o'clock, the way being by the old Watling Street. Leicester was reached in good time, and the expedition was regarded in every way as having been a very successful one.

LETTERS OF IDENTIFICATION.

Below are the letters of identification for Irish counties and boroughs:—

COUNTIES.

CASES DISMISSED.

At the Loughborough Petty Sessions, Mr. Ellis, Shardlow, was summoned for driving a motor-car, at Castle Donington, at a speed dangerous to the public, having regard to the amount of traffic on the highway, or which might reasonably be expected to be on the highway, on March 17th. Mr. Ellis said on the day in question he had been to Ashby, and on the return journey he overtook a car whose occupants he did not know. At the time he passed the constable's house he had his engine throttled, and his side-brakes on, and was not going at a greater speed than six to eight miles an hour. While going down the hill at that speed the other car passed him, but not going at much greater speed. There was no racing with the cars in any way. Samuel Barratt, who was with the last witness, gave corroborative evidence. The Bench dismissed the case.

James Ludlow, of London; Arthur Gadsden, of Leamington; and Maurice Egerton, of London, were charged at Towcester on separate summonses with driving motor-cars to the danger of the public, at Foster's Booth, on April 18th.—Mr. T. Staplee-Firth appeared on behalf of Ludlow. The evidence of P.C. Packer was to the effect that defendant was travelling at a rate of fully 34 miles an hour, and that it was particularly dangerous because there was an auction sale near the road along which the car was travelling. The police officer held up his hand, and the driver immediately stopped—within six yards. A witness corroborated as to the speed, but disagreed with the constable as to the direction in which the car was proceeding, and it became evident that some mistake had been made, apparently the constable confusing the different cases. The magistrates dismissed the case, and after hearing the evidence against Gadsden, who was represented by Mr. A. J. Darnell, of Northampton, decided on a similar course with that case. On the application of the Deputy Chief Constable, the case against Egerton was withdrawn.

Mr. Maurice Hewlett, the novelist, was caught in the well-known police trap at Nether Wallop, near Andover. The case came on for hearing at the Andover Petty Sessions on Friday, the 29th April, Mr. Staplee Firth conducting the defence. Ultimately the Bench dismissed the case.

At Guildford, William du Cros, 14, Regent Street, was summoned for driving a light locomotive at a greater speed than was reasonable and proper, having regard to the traffic, in London Road, on April 17th. Mr. W. S. Turner said he should demand that the prosecution prove the Local Government Board Order. As a matter of fact, the Local Government Board did not have any regulation with reference to the speed, and he should ask the case be dismissed.—The magistrates' clerk joined issue on that point, citing the Order of 1896.—Mr. Turner, however, quoted from the Act and Order of 1903, which stated that the 1896 Order was repealed. In the 1903 Order there was no allusion to speed in towns.—The Chief Constable (Mr. Worlock) applied that the summons should be amended.—Mr. Turner objected.—The Magistrates' Clerk: He can have a new summons.—Mr. Turner again objected. His client having once been put in "jeopardy" could not again be summoned in respect of the same offence.—Mr. Worlock asked the magistrates not to dismiss the case on its merits, but on a technical point.—The magistrates, advised by their clerk, dismissed the case, but refused to make any statement as to a fresh summons being granted.

At the Portsmouth Police-court, in the Portsmouth Town Hall, Edward Doudney, of "St. Cecilia," the Retreat, Southsea, was summoned for driving a motor-car to the danger of the public in Castle road, Southsea, on April 16th.—Mr. A. T. Prickett (the Chief Constable) supported the information).—The defendant and Douglas Richard Clark, who was one of the occupants of the car, both denied that the car was travelling at a dangerous speed. Another witness saw the car in Castle Road just previously standing still near Hambrook Street. A motor engineer was the other occupant of the car, being there for the purpose of remedying the defective cylinder, and he explained that they were travelling on the second speed at the time, and it would be impossible to get more than twelve miles an hour out of it. The case was dismissed.

CONVICTIONS AGAINST MOTORISTS.

Southport	Dangerous speed.	10s., etc.
Truro	Furious driving.	10s., etc.
Reigate	Dangerous speed.	£3 3s., etc.*
Exeter	Dangerous speed.	£2, etc.
South Shields	Reckless driving.	£1, etc.
Taunton	Reckless driving.	£1, etc.
Edinburgh	No number.	£3, etc.
Loughborough	Dangerous speed.	£3.
Cardiff	Not producing licence.	20s., etc.
Canterbury	No light.	Costs only.
Woking	Driving to common danger.	£1.*
Wolverhampton	Driving to common danger.	£1.
Pollockshaws	No number.	£5.
Bingham	No number.	£1.

* Licence endorsed in addition to fine imposed.

POLICE TRAP.

All motorists who have occasion to travel on the Basingstoke road should look out for a police trap at Hook, some little distance the London side of Basingstoke. The trap in question is a quarter of a mile, and can be easily identified, as part of the measured distance is over a new railway bridge. A plain clothes sergeant and a constable in uniform work the trap, and the time is taken at each end by means of signals and two stop watches.

At a meeting of the Cycle Engineers' Institute last week it was unanimously agreed to change the title to the Automobile and Cycle Engineers' Institute. Mr. H. Austin, of the Wolseley Tool and Motor Car Company, Limited, has been elected president of the new body for next year.

TO CORRESPONDENTS.

All communications intended for insertion in this Journal or relating to Editorial matters should be addressed to The Editorial Department, Motor-Car Journal, *39 and 40, Shoe Lane, London, E.C., and must be written on one side of the paper only. Letters must in all cases be accompanied by the name and address of the writer, as no notice will be taken of anonymous communications.*

The Editors cannot undertake to return MSS. or drawings, although every effort will be made to do so in the case of rejected communications. Where such are regarded as of value, correspondents are requested to retain copies.

To insure insertion communications and contributions must be in the Editor's hands by Tuesday forenoon of the week in which the same are intended to appear. Disappointment may be caused by non compliance with this rule, and to avoid this earlier receipt, if possible, is necessary.

The Editors do not hold themselves responsible for the opinions expressed by their correspondents, or for statements and facts which do not appear in the editorial columns.

The Editors and Publishers beg also to state that they will accept no responsibility for unsolicited contributions, even if used, unless payment for same is directly specified in forwarding, and the terms arranged before publication.

THE

Motor-Car Journal.

VOL. VI.] LONDON, SATURDAY, MAY 14, 1904. [No. 271.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ELSEWHERE we have much to say concerning the Eliminating Contests which have been proceeding in the Isle of Man, and the description of a run around the course will be read with interest by those who follow the accounts that appear in the daily press, as well as the incidents of the event that we have gleaned from competitors and others for exclusive publication in our next issue. Read in conjunction with the telegraphic summary of the eventful day of Tuesday it will give our readers some idea of the difficulties encountered—difficulties which have been generally acknowledged, although somewhat exaggerated in many quarters.

◆ ◆ ◆

Manx Names.

NOW that the interest of British motorists is inclining towards the Isle of Man, many will be glad to have Mr. A. W. Moore's work on the surnames and place-names of the Isle of Man, published by Mr. Elliot Stock. Mr. Moore is the Speaker of the House of Keys, and has written largely and learnedly on the history and folk-lore of the island. His qualifications for his present task are undoubted, and the volume is not only filled with much information on Manx names in particular, but also gives a good insight into the history of the island.

◆ ◆ ◆

Our Identification Card.

THIS week every reader of the *Motor-Car Journal* will receive as a supplement a neat card of a size suitable for the pocket, the possession of which will enable him to obtain some idea of the place of origin of the cars that promenade the streets bearing letters which are mystic symbols—no more, even to other men on the car. We shall be glad to supply further copies to subscribers wishing to hand them to friends. Advertisers, too, will be given extra copies for distribution to clients, on making application to the Publisher of the *Journal*, 39–40, Shoe Lane, E.C. Prompt application for these supplies is necessary, as an early exhaustion of the first edition is anticipated.

◆ ◆ ◆

Why Not India?

SUCH is the conundrum propounded by a Calcutta contemporary in connection with the Eliminating Race for the British Gordon Bennett Cup team. India, in the cold weather, according to our journalistic confrere, offers an unrivalled field to the motorist. "The race in Ireland, after the most elaborate arrangements and precautions, was unsatisfactory. At given points on the course each machine had to pull up, thus necessitating an elaborate system of time-keeping, which does not commend itself to the ardent motorist. In the first place it would be no very difficult task to make even more elaborate arrangements than were made in Ireland for a big race. The country also lends itself to such a form of sport. One or even two hundred miles of the Grand Trunk Road could be placed in proper order, with the necessary patrol, which in Europe has proved so costly, on which a daily stream of motor-cars either practising for some race, or being tested with a view to their improvement, could career. For months on end there would be no fear of rain or sticky roads. The cost of carriage to India would not stand in the way of the wealthy patrons of the pastime, or of those large manufacturers who only need this opportunity to develop their trade. All these reasons, and many more, are to be found in favour of holding the race in India." The reasons may be excellent, but the motorists are not to be drawn in that way.

◆ ◆ ◆

Cost of Operation.

AMONG other well-known motorists who have responded to the suggestion that they should give our readers some idea of the cost of motor-car upkeep is Lord Edward Churchill, whose letter in our Correspondence columns will doubtless encourage others to state their experience for the benefit of the motoring fraternity. According to the statement, made with such regard to accuracy of detail that it becomes of real value, the gross running cost for a 14-h.p. car the first year was practically £90, from which the saving of railway fares has to be deducted, leaving a net running cost of £65. The car was run one day out of every three, the average daily run being twenty-five miles. This works out to 5d. per mile, and affords a useful basis of comparison of which we invite our readers to take advantage, and let us know the result.

◆ ◆ ◆

The King at Aldershot.

KING EDWARD, accompanied by the Duke of Connaught, paid a visit to Aldershot on Monday, to witness a series of tactical manœuvres carried out by the cavalry and artillery of the First Army Corps. They were received at Farnborough by General French and a number of staff officers, and the Royal party immediately proceeded in motor-cars along the Farnborough road to Cove Common, Aldershot. Throughout the day their car was preceded by two staff officers on motor-bicycles, each carrying a small Royal Standard at the handle-bars. The King and the new Inspector-General showed a keen interest in the manœuvres, and rushing along the dusty roads at a good speed, over Cove Common, across the Elmour Bridge, and backwards and forwards down the Farnborough road, witnessed the gradual development of the grand attack.

◆ ◆ ◆

The Automobile Club and Long Distance Runs.

AT a meeting of the Executive Committee of the A.C.G.B.I. a resolution was adopted to the effect that "a public statement be issued from the Automobile Club, pointing out that some recent long distance attempted non-stop runs had not been held under the auspices of the Automobile Club or under the observation of its officials, and that attention be called to the fact that the club is prepared to properly supervise such runs under regulations which are well known to the trade." It was also resolved that "if the name of the Club appears in public reports of non-stop or other road trials which are not held under the auspices of the Club, those concerned shall be liable to suspension from the right to take part in motor competitions in this kingdom and elsewhere."

A Considerate Surveyor.

THE surveyor to the Kesteven (Lincolnshire) County Council, in a recent report to the Highways Committee, draws attention to the great necessity of some practical method of minimising the nuisance arising from dust during dry weather. The fact, he says, must be recognised that the introduction and general use of motor-cars must revolutionise the conditions and necessities of traffic, and will call for some alteration in the existing method of road making. He further states that he has made a constant study of this subject for some time, and has attended and inspected all experiments that he could possibly reach bearing on it, amongst them being the oiling of roads, the spreading of Westrumite, the tarring of the surface of roads, and the use of tarred macadam. For climatic reasons he does not regard the oiling of roads as of any practical use, while the cost of Westrumite is against its general adoption at present. The tarring of the surface of roads and tarred macadam are now almost past the experimental stage, and he proposes, therefore, with the approval of the committee, to continue to use them in small quantities, so as to ascertain, as far as possible, their adaptability to the needs of the county.

◆ ◆ ◆

Mr. Glidden and party leaving the Hotel Carlton, London, on Friday, the 6th inst., in their 24-h.p. Napier for Scotland, this being the 118th day's drive of their round-the-world trip.

◆ ◆ ◆

Considerate Drivers.

THE A.C.G.B.I. are adopting the policy of insisting on the considerate driving of cars in a way that will, we trust, prove a deterrent to those members of the Club, and they are not wholly unknown, who have often shown a disregard of the welfare of the movement by wanton driving in the most reckless fashion. It is rightly acknowledged that those in charge of high-powered cars are not the only sinners, but that many of the little vehicles are made objectionable on the road by the discourtesy of their drivers. Elsewhere we give the main paragraphs of a letter received on the subject from the A.C.G.B.I., and hope some speedy abatement of the nuisance it exposes may follow.

◆ ◆ ◆

An Objection to Tramways.

AMONG the witnesses last week before the Select Committee of the House of Commons which is considering the Bill dealing with the extension of the Hounslow tramway from Baker Bridge to Staines was the Hon. J. Scott-Montagu, M.P., who described the inconveniences arising from the tramways in the High Street, Brentford, where it was very difficult for the ordinary traffic to get through, and extremely difficult for motor-cars to pass tramcars going in the same direction. With granite in the tramway track and macadam at the sides, motor-cars would be very liable to side-slips. Wood over the entire road would be much preferable. The Committee found the preamble of the Bill proved in regard to the Staines extension, subject to the requirements of the Middlesex County Council in regard to width of road, drainage, wood-paving as agreed, and lighting at cross and lateral roads.

◆ ◆ ◆

Motor-Car Imports and Exports.

NO less than 559 foreign motor-cars were imported into this country during last month, their value being returned at £170,757. "Parts" were responsible for £31,742, bringing up the total imports for April to £202,499, as against £189,907 in the preceding month, and £153,955 in April, 1903. So far this year, that is to say for the first four months, the imports stand at £720,173, or roundly £100,000 more than in the same period of last year. Passing now to the exports of British automobile productions, the returns are somewhat disappointing, only 42 vehicles being shipped last month, these with the "parts" being valued at £20,391. For the four months ending with April the exports are, however, returned at £106,507, £18,000 more than in the corresponding four months of 1903.

◆ ◆ ◆

Regulations for Heavy Motor Vehicles.

ELSEWHERE in the present issue of the *Journal* we publish the recommendations made by the Departmental Committee appointed by the President of the Local Government Board in January last, "to inquire and report with regard to any regulations which should be made under section 6 of the Locomotives on Highways Act, 1896, and section 12 of the Motor Car Act, 1903, as respects any class of vehicle for the purpose of increasing the maximum weights of three tons and four tons, and with regard to any conditions as to the use and construction of the vehicles which should be made by any such regulations." The Committee express themselves fully satisfied in their report that the development of the heavier kinds of motor-car traffic is at present unduly restricted by the maximum unladen weights prescribed by section 1 of the Locomotives on Highways Act, 1896. In drawing up the new regulations, however, it was necessary to bear in mind the distinction between motor-omnibuses and other passenger vehicles, and motor-vans and lorries used for the carriage of goods only, the requirements of the two classes of traffic being manifestly different. The Committee had also to bear in mind that a special class of motor-car might have to be provided for military purposes, and that tyres constructed of metal must be placed in a different category from those constructed of a non-metallic resilient or elastic material such as rubber. As a rule the Committee have confined their recommendations to those provisions which seemed essential to protect the public and the roads, as they were anxious not to fetter unnecessarily a growing industry. It was suggested to the Committee that a regulation should be made allowing motor-vehicles manufactured in this country for export which do not comply with the regulations to be tested on the roads or to be driven to the port of embarkation. They think that local authorities might be authorized to permit the use of any road in their area for these purposes, subject to any conditions which they deem fit to impose.

◆ ◆ ◆

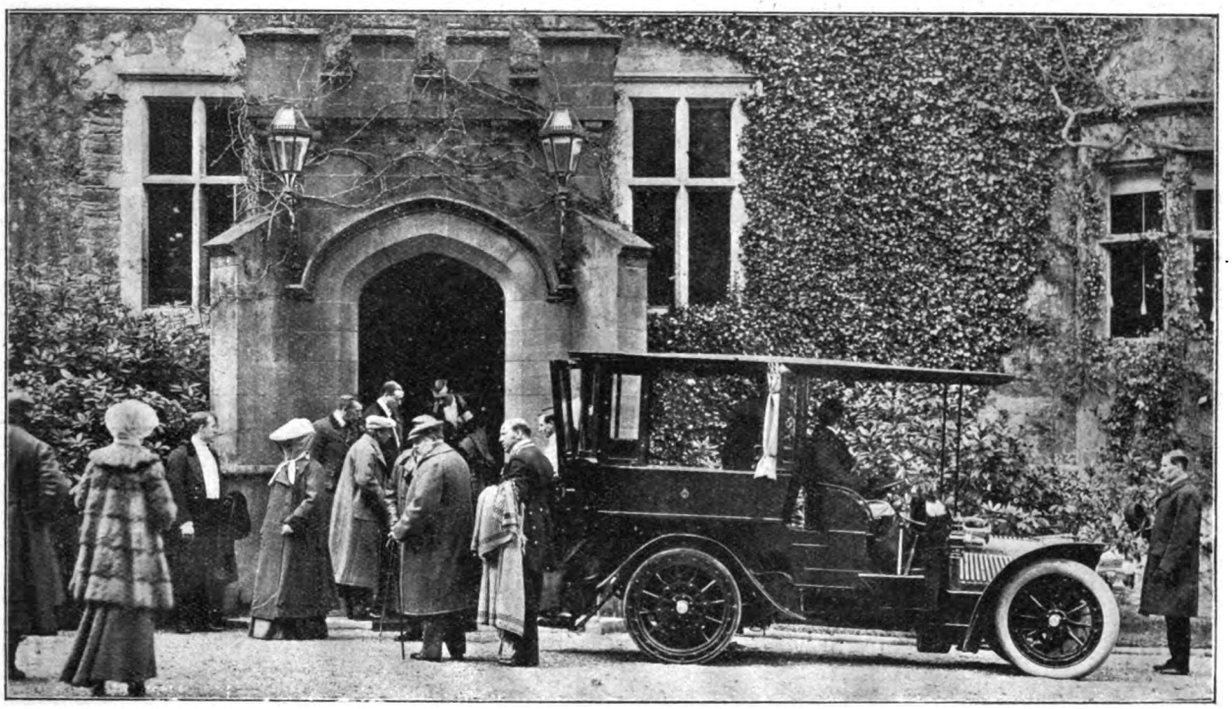
The Glasgow to London Trial.

ARRANGEMENTS are now well in hand for the Glasgow to London trial which the Western Section of the Scottish Automobile Club will hold on the 19th and 20th inst. The chairman and honorary secretary of the Section drove last week-end from Glasgow to London and back over the trial route in order to fix the various points at which the Observers' stages are to be completed and time recorded, and to make other necessary arrangements. A list of the thirty-one vehicles which have been entered for the event has already been given in the *Journal*. The programme which has been issued, and a copy of which has been sent us, is exceedingly complete. From it we learn that the start will take place from Glasgow at 5.30 a.m. on the 19th inst., the first day's journey being as far

Digitized by Google

as Leeds, which will be left in the order of arrival at 6 a.m. on the 20th inst. On the first day there will be a fifty minutes' stop at Penrith, and one of equal duration at Stamford on the second day. There will be minimum times for the various stages in the schedule. Arrival at the end of a stage in advance of the minimum allowed will entail the loss of one mark for each minute of prior arrival. On the second day's journey a hill-climbing competition is included in the programme. This will be held on Woodcock Hill, Elstree, and will be made from a standing start.

◆ ◆ ◆



Restrictions in Forfarshire.

THE County Council of Forfarshire has followed the example of the Aberdeen County Road Board in setting itself against the recommendation of Mr. Graham Murray, the Secretary for Scotland. A special committee appointed in connection with the Motor Car Act submitted several recommendations to the Council at its meeting last week as to restrictions on certain roads for motor-car traffic. Mr. Alexander Lyell, Montrose, moved that, seeing the Secretary for Scotland was not desirous of the Council taking immediate action, they should delay the matter. What was required was uniformity of action as regards restrictions, and it would never do for different counties to have different recommendations. Mr. William Smith, Balzeordie, moved, however, that they approve of their Committee's report, and adopt its recommendations. He hoped the Council would never submit to be dictated to by the Scottish Office, the Secretary for Scotland, or any of his subordinates. A long discussion ensued, but in the end the reasonable resolution of Mr. Lyell was rejected, and that of Mr. Smith adopted.

A District Meet.

THE first meet of the members of the Yarmouth, Lowestoft, and Beccles district of the Norfolk Automobile Club was held at the Swan Hotel, Southwold, on Saturday afternoon, under very favourable conditions, the weather being all that could be desired, and the roads good. The following were among those present:—Mr. and Mrs. Williamson, Yarmouth; Mr. and Mrs. H. Chamberlin, Yarmouth; Mr. and Mrs. A. E. Lark, Yarmouth; Mr. and Mrs. E. W. Bayley, Lowestoft; Mr. Gilbert Morse, Lowestoft; Mr. and Mrs. T. P. Angell, Beccles; Mr. and Mrs. J. W. Brooke and Mr. and Mrs. Maudsley Brooke, Lowestoft; Mr. and Mrs. T. Bradley, Yarmouth. Twenty-five members and friends having partaken of an excellent tea provided by the manageress of the Swan Hotel, a homeward start was made at 5 p.m, the run and meet passing off very successfully, without mishap of any kind. The next meet will be at the Bridge Hotel, Potter Heigham, on the 2nd June.

THE KING'S VISIT TO IRELAND.

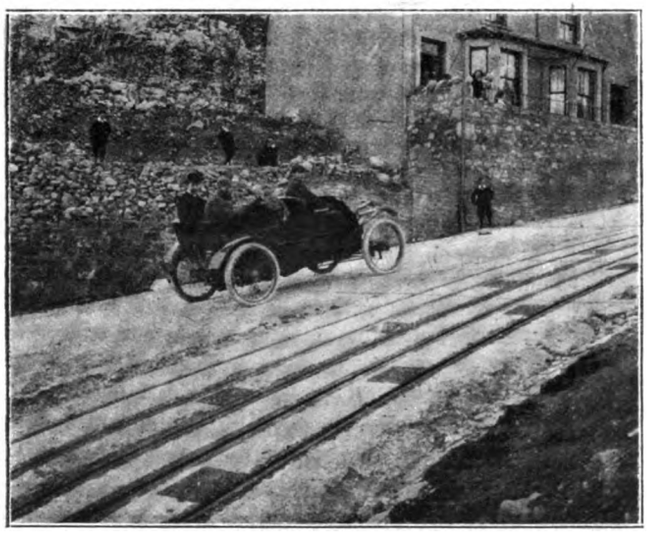
Postal Motor Deliveries.

IT is rumoured that the Great Western Railway Company has secured the contract for the carrying of the mails to the Lizard. Hitherto the mails have been carried by mail cart from Helston, and had to wait the arrival of the 'bus from Penryn, reaching the Lizard just before 10 a.m. Under the new arrangement the mails will be brought from Gwinear Road to Helston by train, and thence by motor to the Lizard, reaching the latter place about 8.45. There will be another mail

Digitized by Google



later in the day, thus giving two mails in and out. The new service, it is stated, will commence early next month, and proves that the enterprise of the provincial postmasters is greater than that of the central authorities in London.

◆ ◆ ◆

Dust.

With the advent of fine weather and undampened roads the dust nuisance again becomes a feature of ordinary touring that is both distressing and irritating. The local authorities should co-operate with motorists in seeking a remedy. For it is not wholly the fault of the motor-car. A sudden gust of wind will often throw the dust up like a cloud, and the motor-car can only be regarded as aggravating the matter. In no sense can it be held wholly responsible. Often have we urged that the subject is one for the consideration of road surveyors and those similarly engaged. Hence the pleasure with which we record the fact that the Godstone Urban Council is now giving a trial to one of the new materials with which it is suggested to keep the dust within bounds. The test will be a severe one, for motor-car traffic along the London road is continuous every day in the week, and the dust raising capabilities of automobiles cannot easily be beaten. The road to London continues through the district of the Godstone Rural Council, and the surveyor has secured permission to expend £10 upon experiments on the public highways. We shall be glad to hear of other local authorities similarly enterprising.

A Useful Handbook.

The various motor-tyre companies have for long been noted for their enterprise, but in publishing "The Continental Handbook for Automobilists in Great Britain and Ireland" the Continental Caoutchouc and Guttapercha Company have easily beaten their record in this respect. The handbook is a work of reference which will be found almost indispensable by motorists, no pains have been spared to make it as complete as possible. After a table of contents, a preface, and a calendar, we find the proper hours for lighting lamps, and a comparative speed table. Then the full text of the several enactments relating to motor traffic in Great Britain and Ireland appears, also the Local Government Board Regulations under the Act of 1903. These are followed by the regulations as to the use and storage of petrol and the taxes on motor-cars. Then comes a clearly-written and well-illustrated treatise on "Clipper Continental tyres: How to Treat and How to Repair them," which extends to about fifty pages. The full membership roll of the Automobile Club is given, and excellent articles on How to Clothe while Touring," "Hints on Assurance," and "The Cleaning and Care of Cars." Another useful feature of the work is "The Automobilist's Gazetteer," which takes the form of an alphabetical list of towns in Great Britain and Ireland, and under the name of each town gives its county, railway stations, post office, telegraph office, telephone fee to London, and altitude above sea level, following with addresses of oil and petrol stores, repair shops, garages, doctors, and hotels. A telegraphic code for ordering Continental tyres and a list of motor manufacturers and agents are also given. The railway and steamer rates of the country, Customs regulations re cars for the Colonies and abroad, are other items dealt with, while in a pocket formed inside the back cover is a clearly-printed map of Great Britain and Ireland, showing routes numbered to correspond with the tours given in the text. We strongly recommend all motorists to procure a copy of the handbook, which extends to over 1,000 pages. It is being distributed free by the Continental Company, a small charge being, however, made to cover the cost of postage and packing.

◆ ◆ ◆

Harmony Disturbed.

The other day, at Dewsbury, a motor-car being driven by a London gentleman seems to have run into a brass band, with the result that the harmony of its performance was very much affected. Four musicians were seriously injured, and, in order to complete the tale of woe, the crowd seemed to have turned upon the driver of the misguided vehicle and inflicted such rough usage upon him that he reported the matter to the police. The friends of the injured bandsmen, after having taken them to the hospital, seem to have similarly reported the motorist to the legal authorities, and the result will probably be several summonses and appearances in the local police court. We cannot see any reason why the motor-car should have run into the Ravensthorpe Brass Band in this way, unless, being of Continental origin, it had an idea that British bands have no right in English towns.

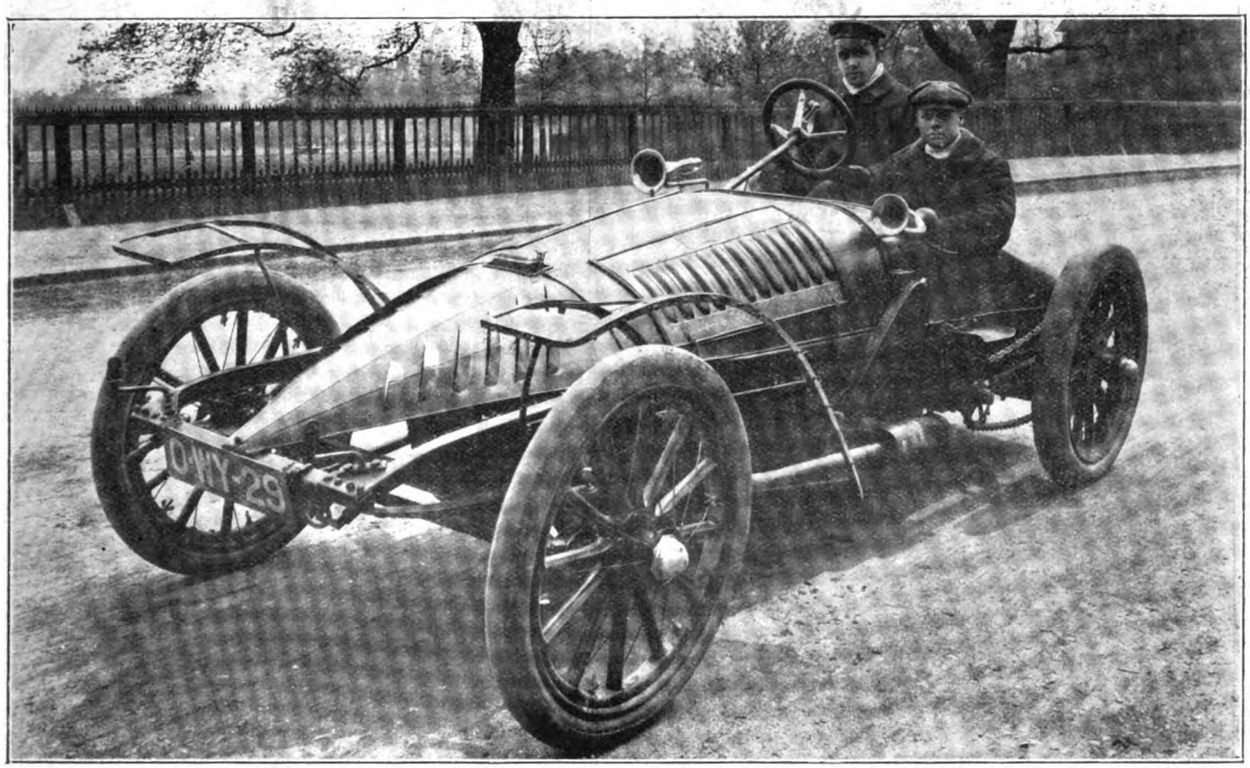
◆ ◆ ◆

Unattended Horse.

We wish motorists would take action on the lines of that of Dr. Woodward, of Worksop, who has just caused a summons to be taken out against a carter who left his vehicle unattended on the high road, thereby causing an obstruction. The doctor was driving a motor-car towards Lindrick Common recently, and after sounding his horn on turning a corner saw a horse and cart standing unattended on the side of the road. He slowed down, but the animal turned round and bolted towards the car, which had to be swerved on to the grass to prevent an accident. The result of the case was that the defendant was fined half a crown; not sufficiently severe a sentence, it is true, but the conviction is useful as showing those in charge of horses that they cannot leave them unattended on the road with impunity. Had an accident really occurred, it would of course, have been attributed to the automobile.

In consequence of a report that the 10-h.p. Decauville is no longer obtainable, the Motor Car Company, Limited, ask us to state that this still remains one of their standard patterns.

At the meeting of the Bute County Council last week it was agreed, on the recommendation of the County Road Board, to prohibit motor-cars in Arran except on the ten-mile stretch between Brodick old pier and Whiting Bay, but it was agreed to allow motor-cycles on all Arran roads, the speed limit for both vehicles to be ten miles per hour.



The directors of Messrs. Brown, Brothers, Limited, in their report for last year state that the profit, after making provision for depreciation, amounts to £27,070. Out of this the dividend on the preference shares, at the rate of 6 per cent. per annum to December 31st last, has been paid, and £1,525, being 10 per cent. on net profits, set aside. The directors having further provided a sum of £2,000 as a special reserve for depreciation of investments, recommend that a dividend at the rate of 6 per cent. per annum be paid on the ordinary shares, that a further sum of £3,000 be carried to the reserve fund, and the balance of £3,333 carried forward.

Motoring in Manxland.

SATURDAY.

WE arrive—a weary, sickly group of persons passing through trial and tribulation to Douglas Harbour. The "Queen Victoria," the second largest boat on the Liverpool-Douglas service, makes her first trip of the season and encounters a rolling of the sea that gives us a sense of vibration never experienced on an automobile. It is a fine day. In the Mersey, the long trail of smoke from other steamers reminds motorists of those clouds of dust that arise by day and will not be lowered. But we get beyond the reach of the "teuf teuf," and the sound of the horns. Here is the great ocean; spray dashes over the sides of the vessel, for we travel where no police traps can be laid, and no magistrates would dare to convict.

Mr. C. Jarrett and his Mechanician, Bianchi, on the Wolseley Racer.

It is a goodly company of motorists, and a reunion of Northern, Midland and Southern friends takes place at the lunch hour. Throughout the trip, however, there is a feeling of uncertainty. Men start to play bridge in the cabin, they seek the solace of the vessel's side ere long. Conversation lacks vigour; even the ladies who, with caps and veils opening to rearward, indicate their motoring proclivities, seem disinclined to look ahead, and cast wistful glances waywardly. But few escape the contagion, and nearly all arrive at Douglas with a temporary hiatus.

What a relief to be on *terra firma* after such a vibration. Here is the Peveril, the headquarters of the A.C.G.B.I., next the Villiers, with its overflow of Piccadilly, then a succession of boarding houses and amusements sweeping round the bay to the Douglas Head Hotel, where Lt.-Col. Mayhew, Mr. S. F. Edge, Mr. and Mrs. Kennard, and a crowd of Napier enthusiasts have gathered. At the Falcon is the Wolseley headquarters, although Messrs. Austin, C. Jarrott and Campbell Muir rest in the daytime elsewhere. The Darracq champions, led by Capt. A. Rawlinson, are at the Peveril.

MISHAP TO A NAPIER.

There has been a little excitement this morning. Mr. Clifford Earp, who has been driving Napier cars a good many years, although this is his first appearance in a big race, has collided with a house—a very awkward obstruction to attack. In negotiating a corner near Douglas, the axle cap of the front wheel struck the house, with the result that the spokes were smashed and other damage done. Fortunately no one was hurt.

SUNDAY.

Although not allowed to take their racers on the course during Sunday, most of the competitors are toddling round to familiarise themselves with its corners and peculiarities. Driven by Mr. Austin, Mr. C. Jarrott, and Mr. C. Muir are passengers on a touring Wolseley, and Mr. J. W. Stocks is at the wheel of a car of about one-sixth the power of that he is to negotiate on Tuesday.

The "Douglas" has brought a host of officials. Colonel Holden, Major Lindsay Lloyd, Professor Vernon Boys, Mr. Basil Joy, and several others are discernible in the throng, which includes quite a score of large cameras, a motor-car or two and a spare wheel, for which two or three gentlemen in the waiting crowds are anxiously looking. This is the first time a steamer has landed passengers on the island on the Sabbath—and, as if to show their disapproval of the arrival, only a few Manxmen assemble on the pier. Here is a quiet little place, far away from the mad rush of cities and the gaieties of the river and the park. Unfortunately there is a dearth of news. No one seems to know anything. The multiplicity of departments adds to the difficulty of obtaining news, and we sigh for some official programme that is likely to be adhered to. During the day rumours as to differences between the Races Committee and the competitors have been flying about. These have culminated

Digitized by Google

in a conference between the two, at which the drivers have presented a demand that the original intention of a race shall not be altered. There seems to be unanimity amongst the competitors with regard to their intention of racing, but we feel the Races Committee will suggest a compromise which will be accepted by the entrants as a good way out of the difficulty. For, truth to tell, no one likes the course as a racing track.

Up to date, forty-six cars of all kinds have arrived, and are finding quarters at Douglas and Ramsey. No other places seem to have been favoured by the motorists, who naturally regard Douglas as the centre of observation.

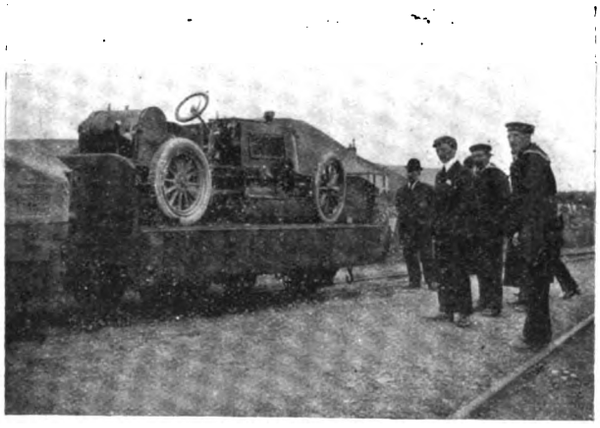
A DASH AROUND THE COURSE.

The course for the Eliminating Test is one to try men as well as cars; and strong nerves as well as good machines will have an important bearing on the result. Comparisons with the route of the race last year in Ireland are inevitable; they are also misleading, for it may at once be said that the two routes are as different as automobiles and donkey barrows. The Irish course was practically level, only a few ups and downs disturbing the contour of the road, but here mountains have to be scaled and descended. The Manx course is only a little more than half the length of that in the Emerald Isle. It has fewer long stretches and quite as many tricky corners that will quicken the pulses of the drivers and lower the speed of the cars. These are general impressions; but we will describe an actual run over the fifty-one miles and one furlong on a speedy vehicle, driven by one of the most popular of northern motorists, Mr. Leonard Williamson, of Southport.

It is Sunday morning—all Douglas is within doors, and only a few small boys give heed to our going from the Peveril Hotel to the Quarter Bridge, the beginning and near the finish of the race. It is 11.22 a.m. Mr. Williamson sets off for the first control at Ballasalla, eight miles away. The road is narrow, with tall hedges of gorse and green, reminding us of Mr. Hall Caine's description of the colours of the island as being "green and gold." A gentle rise and fall of the road, and we come to a veritable switchback for half a mile, and a further restriction of the roadway to not more than fourteen feet.

Still ascending, the first green flag is seen stretching across the road, and indicating that cautious driving is necessary for a quarter of a mile—at least. Mr. Williamson bears that flag in his mind's eye as his car—a 60-h.p. Mercedes, inclined to be fast—sweeps down hill and rounds a corner towards Richmond Hill. The first sharp turn encountered, the car begins to hasten, and uphill we shoot, where the long slope of Mount Murray takes us to a wider roadway, and amid scenery that becomes impressive.

Great hills rise to the right, their little farmsteads and yellow-lined fields showing up in the increasing glare of the sun—a cheerful feature of the landscape. But the road is the main consideration of those who swallow space as does the Mercedes, and from the distant mountain tops the eye travels to the hedgerows and the houses—peaceful, comfortable homes for the yeomen of this little kingdom.



Here and there a falling roof or a decaying wall throws the mind back to Ireland, but prosperity reappears at the next corner, and Nature smiles upon a land where Want knows no place.

After the next curve on the road is a bit of the curly-wurly—one of those serpentine performances of the ancient road makers

Repairing one of the Darracqs after a Breakdown.

Practising on the Course near Ramsey before the Eliminating Test. [*Midwood, Ramsey.*

Digitized by Google

who were ignorant of Euclid's definition of a straight line. "Are you there?" calls our passenger in the front as we rise to the occasion—the occasion being a bumpy ground that jolts us all two feet above the seat-level and calls to mind memories of the culverts on the Gordon Bennett course of last year. But there are not many of such lifts—for which we are thankful. Crossing the Balla Lona Bridge over the Santon Burn, with almost as sharp a twist as that which made Mageny a terrible name last year, a sharp run carries us to Ballasalla—a pleasant looking village, where caution marks the inhabitants, who rush to doors and close to walls as the car slackens to pass through. Only eleven minutes have passed since Quarter Bridge was left behind.

It is a nearly straight run of a mile and a half into Castletown

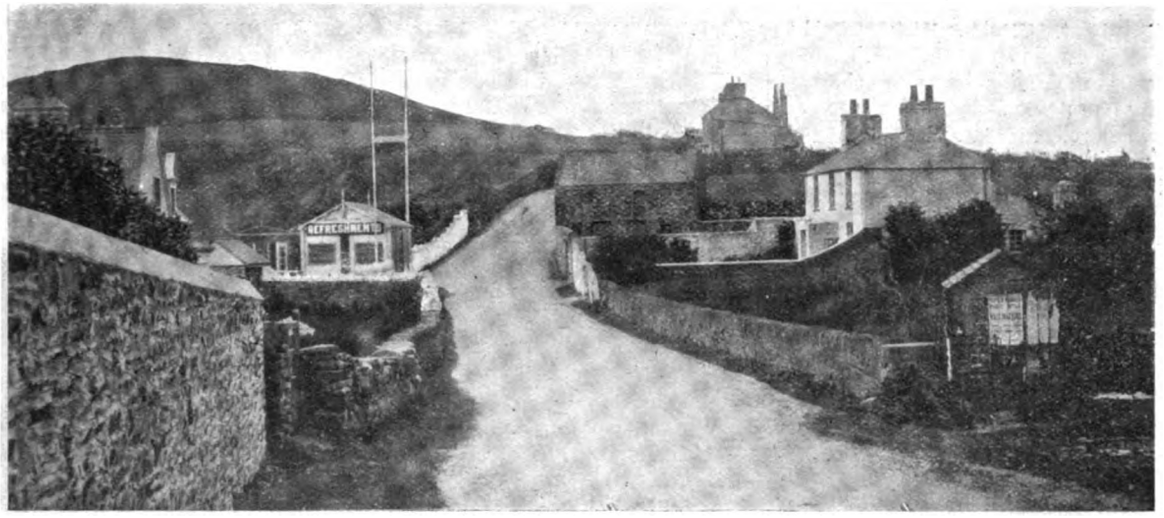

Photo by] The Spot selected for the Hill-climbing Test. [Midwood, Ramsey.

Photo by] The Loch Promenade, Douglas. The Scene of the Speed Trials on Thursday. [T. Keig, Douglas.

—over a bumpy road, unfit for invalids and persons of delicate constitutions. Approaching the ancient town a grand seascape is opened out, the waters of Castletown Bay sparkling in the light. The great square castle and finely-spired church are left behind at the control, which began at Ballasalla, as the track northward is followed somewhat parallel to the southern run until level with Rushen Abbey, and then there is a great dash northward for eighteen miles just beyond Ballaugh before an eastern turn is made to Ramsey.

Towards Foxdale the mountains are reached, and we rise above the area of cultivation. A churchyard is conspicuous between Castletown and Skybright, rendered all the more notable by the black, time-worn gravestones standing in strong contrast to the newly-whitewashed church. It has a strange effect—a study in black and white that will not detain the drivers in the race, unless they fail to negotiate the turn that follows—a curious sort of corner where four roads cross.

A deep dip after Athol Bridge is followed by a steep ascent, long and trying, all the way to Foxdale—just over seven miles from Castletown. We are now up on the hills and among the mountains. To the left South Barrule rises bleak and barren, and we get a glimpse of the picturesque. A straight run for a couples of miles gives Mr. Williamson a chance of chasing the wind, but a danger board is reached just before the next village. Many hay-strewn patches of road direct attention. Evidently the stones have not been properly rolled, the hay being a kind of substitute and reducing the sharpness of granite points; an improvement will doubtless be effected by the day of the race.

Foxdale is a mining village—almost imposing as villages go, with a great main street of tortuous course, along which we travel gingerly, for these roads turn at unexpected places, and corners are too frequent to be pleasant.

The scenery improves; on one side of the road great banks rise to the mountains, and on the other a rivulet and water-wheel combine to add effect to the scene. A quick rush across the Curragh—a mild affair compared with the great Irish heath—and Ballacraine is reached. Here the yellow gorse is most.

Digitized by Google

profuse, tall hedges rising along a road on which the grass has stopped creeping towards the centre—apparently one result of recent motor traffic, if such a word can be applied to cars dashing along between daybreak and breakfast time, as has been the case since the English competitors arrived.

Here the main road to Peel is crossed, and we make for Kirk Michael, another rising stretch of eight miles. We are in a mountain range; Slien Reay, the Greeba Mountain, and Snaefell tower above all else, and into a narrowing road we ascend to breathe the fresh air of these upland heights. It is a cold, clear air—appetising, cheering and healthy. The car feels the exhilaration and gets into a faster stride as the lovely Glen Helen is passed and the turn from Glen na Malish is taken to Kirk Michael. There are some treacherous corners hereabouts; Craig Willie's Hill has a nasty turn at the bottom, and the highest point of the road, known as Cronk-y-Voddey, meaning the "Hill of the Dog," is an awkward gradient. Nearing Kirk Michael a grand panorama of sea and land is unfolded to the eye. In one corner of the landscape an old church adds variety to the scene.

We rush by like a whirlwind and would seem to be dashing on to the sea, which rolls in steady waves along the shore, the deep blue water lingering on the shining sand and appearing to crystallise it into precious metal. But seaward is not our course.

Ordinary people reach Ramsey by way of Sulby. Not so the racing motorists, who have to go across another Curragh—this one more nearly resembling the famous Irish space than does the minor affair near Ballacraine. In an easterly direction we travel along a fine, fast stretch, and as we near Ramsey are afforded another combination of land and water. Here is Ramsey Bay, with the English coast only thirty miles away, a little river, and a little shipping, a pleasant church, some fine shops, and a welcome hotel—the Mitre—at which we draw up, 36 miles and 7 furlongs from the start, at twenty minutes after noon—not fast travelling for a sixty that has done faster times; but the corners and the curves are not to be taken carelessly, and we would rather save our necks than break records.

Here is the fourth control, and only at this point throughout the circuit will the racers be allowed to take in supplies. Ramsey is pleasantly located, but, after seeing to the lubrication of man and motor we set forth again at twenty minutes to one on the most exciting part of the run. It is fourteen and a half miles to Douglas, Willaston Cross, the last of the controls being only one and a half miles from the latter town. The way is by a new mountain road crossing Snaefell—a road with a steep gradient, and with hairpin corners that should not be attempted by motorists in the days of their novitiate. We rise directly the

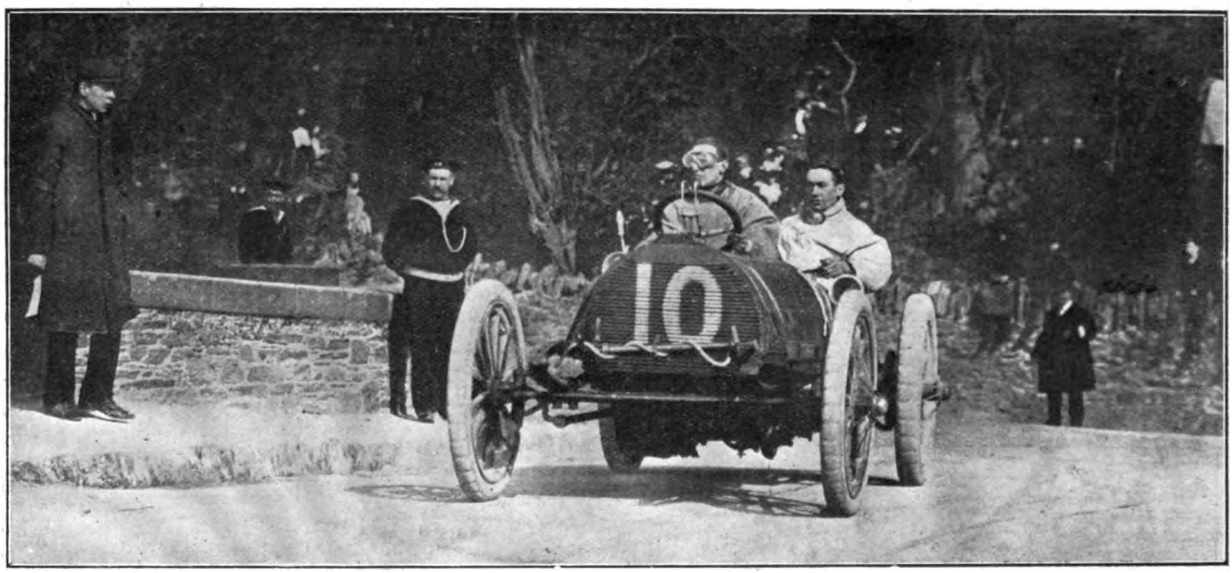

Photo by] **Mr. S. Girling, on the Wolseley, leaving the Quarter Bridge.** *[Campbell and Gray.*

We turn sharply to the right, holding to the car as though to steady its mad career, for the pace is quickening and the blood is up. Here verily is something of that rush of speed of which the late W. E. Henley wrote, and which can only be felt in all its keenness when motoring high among the mountains. There may be joy in speed on the level; but it is but a pale delight after the lurid luxury of an hour in the heights of Manxland. We throw dust—quite unintentionally—on the residence of the Bishop of Sodor and Man at Bishop's Court, and dash over a level crossing into Ballarigh, where a fine old church and a farmyard of quite modern dimensions are the centre of a group of pretty residences. The road opens out; so does the car, after rounding Ballarigh Corner, where those in the race will have to slow down. Beyond the old church—a really quaint building, deserving the adjective employed—the half-mile stretch of sound, level road will give a good chance of showing speed, of which there are too few on the whole course of over fifty miles.

Here Nature makes a bold display, primroses peeping among the grass-grown banks, on which tall trees of sycamore and beech and silver-grey ash rear their branches heavenward, giving a variety to the course which would be tantalising to the competitors but for the fact that their thoughts will be with the road—and the corners.

town is left, the serpentine character of the route being well photographed in last week's *Journal*. At first it is somewhat gradual—as the term goes, up among the mountains—then it is a sudden ascent followed by an equally sharp drop.

A quick turn at the bottom, with driver's hand strong on the wheel, and all ready to jump; the car takes it splendidly. We look around. It would have been a drop—a long drop—had nerve and will not been united to steel and iron at that point. This is no light task to be undertaken merely for the fun of the thing. It is a stern chase to avoid that precipice. We gave it a clear berth and breathed again.

And now there is the climb over North Barrule, eighteen hundred feet above the sea, which now comes in view on the left—a great expanse of water on the one hand and a barren, dreary waste of land on the other. For we are high above the limits of cultivation; only sheep graze here, jumping from boulder to boulder, and finding choice patches here and there where frowning rocks shelter the grass from the wild winds that blow from seaward.

Looking back, a glorious sight retreats from view. The ocean beyond Ramsey, the little town nestling at the end of a great plain, with fields divided by white walls and yellow gor-

Digitized by Google

hedges, make up a view that is worth the worry of the voyage to Manxland with the horrors of a rolling sea.

Still we climb, and now Snaefell is conquered. Our car jibs at nothing, but takes the long climb as though but an incident in the day. Here is a terrible bit of road, and then over the level crossing of the electric railway we bump badly—as badly as over an Irish culvert. The descent is begun. Ahead is a plantation of pine trees. We avoid it at almost a right-angle turn, and then dash by glens in which sycamore and elm and beech give variety to the landscape. For the hillsides are bare, bleak and barren. But what is that? The road here, sixteen feet in width, shrinks at the end of a steep descent, and is grass grown. Is that the way? No turn to the right or the left can be seen. Mr. Williamson peers ahead. Ah! there is a turn—at right angles. Again he succeeds in taking it safely. We have a moment's glance at the six-foot way into which we might have squeezed the car and damaged our bodies.

It is such tricks as that which give danger to the course and makes some men quail. Just before Craig na Baa another glorious combination of sea and land is unfolded. Douglas Bay shines resplendent as the sun beats faintly upon its rippling bosom, while behind we give a glance at Snaefell, Monarch of Manx mountains. Between here and Douglas some awkward if not impossible corners have been widened by the local authorities, and, even now, they are difficult to negotiate, but we get into the stride for the last mile or two and are back in Douglas within half an hour, having run the course in an hour and twenty-eight minutes, running time. It is not an easy course; none of the corners can be taken at full speed, and those who neglect to use their head in the race will surely lose it. In some parts it is risky, in others dangerous—but the surface is good, the road clean of those overhanging trees which bothered the competitors in Ireland last year. Perhaps, after all, there may be reason in the Providence that has ordered the event to be more of a Reliability Trial than of a race—for, as one of the competitors has publicly declared, six times around that course would reduce a car to pieces.

MONDAY.

The weather is glorious. A bright sun, a smooth sea, a delightful atmosphere and hospitable natives provide a quartette of factors in the motorists' sense of enjoyment that are making the visit delightful. Two unfortunate incidents mar the excitement of the morning, for Lieut.-Colonel Mark Mayhew's car has skidded, rushing into a tree and breaking its front axle. Wires have gone to London, and all hope the damage may be repaired by morning, but doubts prevail. The Darracqs driven by the Frenchmen have gone into a ditch, but their damage is slight, and they appear at the weighing in at the Harbour, as does also the Napier, No. 14.

WEIGHING IN.

The weighing in is even more dreary than it was at Naas last year. Then the venue was a delightful market-place with officious policemen amusing everyone with their show of authority. To-day, in a darkly lighted coal shed at Douglas, eleven racing cars are being weighed, some standing along the quayside while their brethren are being scaled within. All the Napiers are easily within the limit; three Wolseleys are accepted; and then comes a wearying wait while the Darracqs are stripped of all superfluous parts to enable them to scale 65 lbs. less than they do.

Earl Russell has just distributed Press armlets which will pass the correspondents where ordinary members of the public will not be allowed. His lordship is the hon. Press Secretary, and the way in which the local reporters have pestered him for information on even the most minute points is entertaining.

Considerable interest is taken in the measuring of the vehicles, which works out as follows:—

		FT.	IN.
No.	1.—Mr. J. W. Stocks (Napier)	7	6¾
No.	2.—M. Edmond (Darracq)	8	4¼
No.	3.—Mr. John Hargreaves (Napier)	7	8¼
No.	4.—M. Hemery (Darracq)	—	—
No.	6.—Mr. Clifford Earp (Napier)	7	8¼
No.	7.—Mr. Campbell Muir (Wolseley)	9	0
No.	9.—Mr. S. F. Edge (Napier)	8	10
No.	10.—Mr. Sidney Girling (Wolseley)	8	7¾
No.	11.—Mr. A. Rawlinson (Darracq)	8	4
No.	12.—Mr. Charles Jarrott (Wolseley)	8	11
No.	14.—Lieut.-Colonel Mark Mayhew (Napier) ..	10	10¼

Nos. 5, 8 and 13 have not been apportioned.

THE RULES OF THE RACE.

Following the exciting conference of last evening comes some supplementary instructions to drivers, calculated to secure more speed tests, but, as we anticipated, giving way but slightly on the main point at issue, viz., whether the test was to be a mere trial or a race. A reference to the regulations published in last week's *Journal* shows that the main alterations are the following:—The course is being divided into sections and for each a scheduled time has been fixed, and no advantage will be gained by any competitor covering the section in less than the scheduled time, but if he take longer than the scheduled time the fact will be noted. Instead of two speed tests there will be three, viz., three miles straight, half mile on the flat, and 2¼ miles hill-climb. The new test of three miles will commence at the third milestone from Castletown.

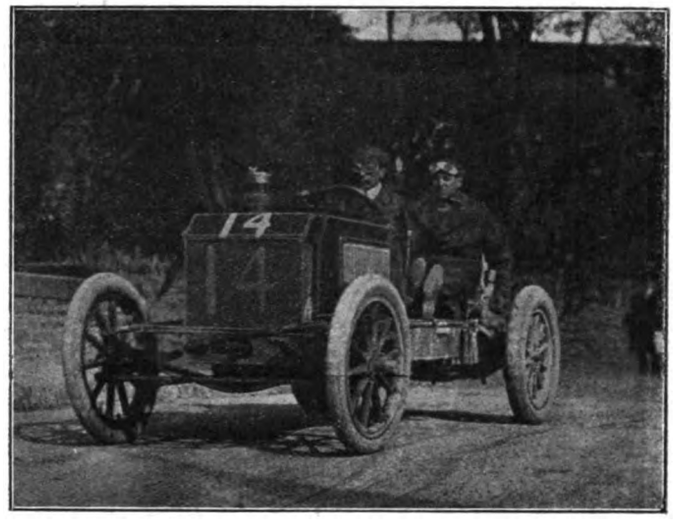

Photo by] Lieut-Col. Mayhew leaving Quarter Bridge. *[Campbell and Gray.*

There are now to be four sections, the scheduled time for covering them being:—

	Miles.	Furlongs.	Minutes.
Quarter Bride to Ballasalla	8	0	10
Castletown to Kirk Michael	16	0	22
Kirk Michael to Ramsey	11	2	15
Ramsey to Willaston Corner	13	0	18

THE ELIMINATING TEST.

(By Telegraph.)

Douglas, Tuesday, 8 a.m.

The scene at Quarter Bridge is an animated one. The rocket brigade have paraded, and elsewhere the Volunteers and the lifeboat crew have been requisitioned, while many of the sailors from H.M.S. "Spartan," which has been laying off the bay for some days, have come ashore to assist the special constables. The Corporation Grand Stand is well filled, and the crowded state of Douglas testifies to the interest in the event.

Tuesday, 10-30 a.m.

In glorious weather Major Lloyd starts Stocks away on his Napier car for the long run. He goes steadily away up the hill. Five minutes later, Hargreaves, also on a Napier, snorts off in jumpy style. Then follows Clifford Earp, whose Napier is

Digitized by Google

fitted with Palmer tyres, and after him Campbell Muir on one of the Wolseleys; the latter makes the best start so far. Next to be dispatched is Mr. S. F. Edge, who has with him Mr. Cecil Edge as mechanician, both wearing blue caps. Girling on the Wolseley, who is the next to be dispatched, makes a good start. Jarrott, with the faithful Bianchi as mechanician, meets with a warm reception as he gets away with ease. Sensation! Where are the Darracqs? Hemery arrives late—the car, minus its bonnet, booming like a Gatling gun. Suddenly, and without warning, he shoots round the Quarter Bridge, and is away before the officials are ready; like a whirlwind, he dashes forward in a cloud of smoke, and is at Ballasalla in eight minutes, two minutes ahead of the scheduled time. Edmond on the second Darracq, who now appears and is officially started, romps up the hill after Hemery. It is now a quarter past ten. and Mr. Mark Mayhew arrives on his Napier and gets away nicely, Captain Rawlinson, on a Darracq, being the last to be dispatched.

RAMSEY, Tuesday, 1 p.m.

We are now at Ramsey, where fine weather is being experienced. We have just heard of mishaps to the Wolseley cars driven by Campbell Muir and Jarrott, but no confirmation of the accidents is as yet obtainable. It is a general holiday here, all the shops being closed, the town being almost as quiet as on a Sabbath day. There are very few visitors from England, the Bungalow at Snaefell being the point most favoured by spectators. Mayhew's Napier car was quickly fitted with a new axle, which arrived by this morning's boat. Only eight competitors are now left in the race, the drivers of the three Darracqs having abandoned. A new style of starting has been adopted on the present occasion by Major Lloyd, who waves a flag to Professor Boys, by whom a flag is dropped to effect the start. The new method, which is due to Major Lloyd, is a great improvement on last year's arrangement. Hemery's going was remarkably Gaelic—a glance at the road, a spurt forward, and away he went at a mad rush that nonplussed the starter and scattered the officials.

DOUGLAS, Tuesday, 8 p.m.

Ramsey is an important control; thither we journeyed after having seen the start at Douglas. On arrival we learned that Edmond had given up, he complaining that oil had splashed on his face until he could not see. After thus declaring his intention of abandoning, he subsequently went off again at a terrific speed; in fact, his pace up the hill from Ramsey was the fastest of all. Jarrott was delayed a long time owing to a damaged gear wheel, which, it is reported, was broken before the start. Hargreaves was also delayed, he having to stop to adjust the clutch and put on a new outer cover. Under Mr. Baisley's direction the Dunlop Company's men effected a very speedy fitting of the new tyre, this being done in five minutes, as compared with the twenty taken in putting a new tyre on Campbell Muir's car at Kirk Michael. Campbell Muir stopped at Ramsey owing to overheating, and the Wolseley space was instantly turned into an engineering shop to effect the necessary repairs. Three hours later he crossed Snaefell—his chances gone. Edge arrived, looking fit, and Jarrott met with a great reception, after a delay at Castletown, owing to a broken inlet valve. At Ramsey there was a great crowd of ladies, among them being Mrs. Mayhew, anxiously awaiting the appearance of her husband. Sir Hickman Bacon sported the Wolseley colours. The officials at Ramsey were Captain Skeffington Smyth and Mr. Claude Johnson. Girling came in, his car going regularly and well, and his chances were highly favoured. Hargreaves, who was the first to reach the control, made the best time in the second round—1 hour 16 minutes, Edge being 5 minutes lower. Jarrott and Stocks' time was 1 hour 28 minutes, and Earp's 1 hour 38 minutes. The tyres all seemed to be going well, the only difficulty experienced being from nails, which were rather plentiful on the roads. Girling had to repair a tyre on the second round, at the Quarter Bridge. Captain Rawlinson only drove 125 yards, when he had to give up owing to a broken cardan shaft.

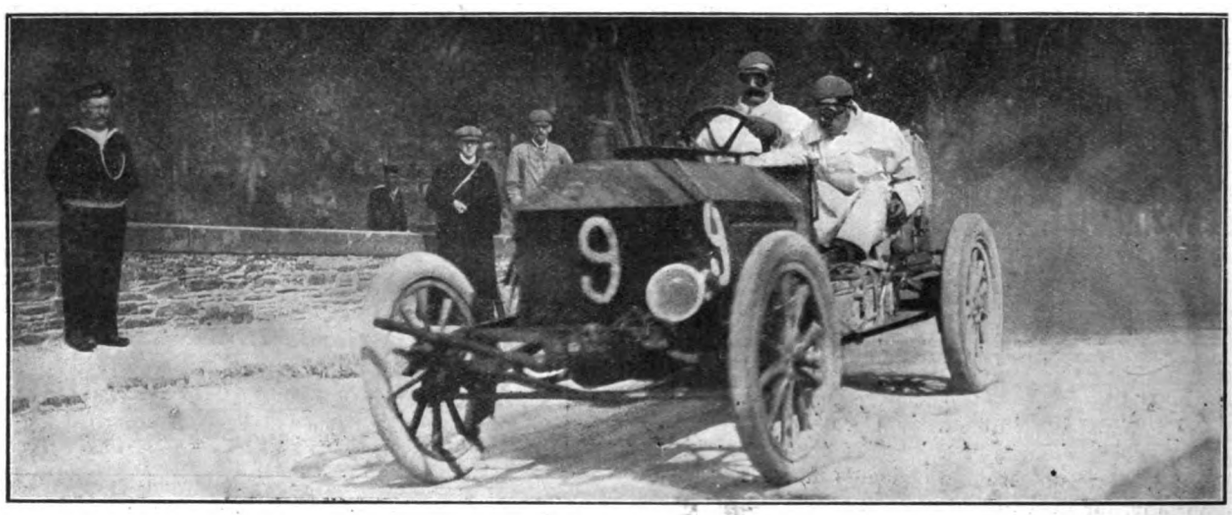

Photo by] **Mr. S. F. Edge leaving the Quarter Bridge.** *[Campbell and Gray.*

He also withdrew the other drivers of the Darracq cars—Hemery and Edmond—because of the brakes.

The chief officials were:—At Ballasalla, Mr. Ochs; Castletown, Mr. R. E. Phillips; Kirk Michael, Sir Arthur Arbuthnot and Sir W. Browning; Foxdale, Mr. M. O'Gorman. The inspection car for the Southern circuit was the 60-h.p. Mercedes, driven by Mr. G. Higginbotham, while Mr. Leonard Williamson drove his 60-h.p. Mercedes as the inspection car of the Northern circuit. Still a third 60-h.p. Mercedes, that of Mr. Kirk, was employed to announce the finish. Mr. Basil Joy accompanied Mr. Higginbotham on an inspection run round the course before the race.

No official times being available, all the figures are subject to revision. Those given in the following tables may, however, be regarded as approximately correct. The times at Quarter Bridge were as follows:—

	a.m.	a.m.	p.m.	p.m.	p.m.	p.m.	Gross running time. h. m.
Stocks ...	9.0 ...	10.38 ...	12.11 ...	1.40 ...	3.11 ...	4.45 ...	7 45
Hargreaves	9.5 ...	10.31 ...	12.35 ...	2.8 ...	3.45 ...	— ...	—
Earp.....	9.15 ...	10.42 ...	12.26 ...	2.2 ...	3.26 ...	4.47 ...	7 32
Muir	9.20 ...	4.15 ...	— ...	— ...	— ...	— ...	—
Edge	9.25 ...	10.46 ...	12.21 ...	1.45 ...	3.31 ...	5.20 ...	7 55
Girling... ..	9.30 ...	11.10 ...	12.50 ...	2.14 ...	3.50 ...	5.30 ...	8 0
Jarrott.....	9.35 ...	10.55 ...	12.45 ...	2.10 ...	4.10 ...	5.34 ...	7 59
Mayhew ...	10.0 ...	11.0 ...	12.14 ...	3.41 ...	— ...	— ...	—

Digitized by Google

Muir started fourth, but was detained at Ramsey, while his car was repaired, and it was not until four o'clock that he crossed Snaefell, reaching the finish of the first round fifteen minutes later. His car travelled well, but he found the road very bumpy, and, like all the other drivers, had great difficulty in keeping his seat. At times it seemed as if all the four wheels of the car were off the road.

The times for the half mile tests were :—

Stocks	32⅘ seconds	Girling... ...	29⅘ seconds.
Hargreaves ...	26⅗ ,,	Jarrott... ...	27⅘ ,,
Earp	28⅗ ,,	Mayhew ...	25⅘ ,,
Edge	24⅗ ,,		

The above are the quicker of the two times taken.

Up at the Bungalow at Snaefell, 1,800 feet above the sea level, we made special notes of the times at which the competitors arrived on the different rounds. They were as follow :—

	a.m.	a.m.	p.m.	p.m.	p.m.
Stocks	10.24 ...	11.56 ...	1.27 ...	2.58 ...	4.44
Edmond	11.47 ...	— ..	— ...	— ...	—
		p.m.			
Hargreaves ...	10.18 ...	12.22 ...	1.55 ...	3.28 ...	—
Hemery.....	11.13 ...	— ...	— ...	— ...	—
Earp	10.28 ...	12.30 ...	1.47 ...	3.23 ...	4.45
	p.m.				
Muir	4.0 ...	— ...	— ...	— ...	—
	a.m.				
Edge	10 35 ...	12.15 ...	1.29 ...	3.17 ...	5.10
Girling	10.39 ...	12.39 ...	1.59 ...	3.32 ...	—

Photo by] Stocks on Snaefell Mountain. *[Campbell and Gray.*

The order of arrival at the Bungalow is interesting. Hargreaves, who started second, overtook Stocks before Ramsey was reached, and he arrived several minutes ahead of him at Snaefell. Earp, Edge, Girling, and Jarrott came next, the two Frenchmen following. Only seven of the competitors made a second round. Stocks regained his place, while Hargreaves, having taken over two hours owing to tyre troubles, fell into fourth place in the third circuit. Both the Wolseleys had started too late to hope to catch up the Napiers, but their consistent running was the feature of the contest. They kept fifth and sixth positions throughout the race—a tribute to the way in which they were handled, as well as to the cars, which behaved capitally. On the third round Edge gained on Earp and retained that position till the last round, when the firing of his petrol tank caused a long delay. The float punctured, and the friction set up by the brake caused sufficient heat to fire the petrol, which leaked. Mayhew held on gamely, but only made three circuits over the mountain road. On the fourth round one of the springs of his car broke at Castletown, from whence he returned to Quarter Bridge.

DOUGLAS, Tuesday, 8 p.m.

In the temporary motor house here four Napiers and two Wolseleys are now stored for the night, under the control of Mr. Burrows, who was also responsible for the work of "flagging" the course and measuring the speed sections—a laborious work excellently performed. Mayhew and Muir's cars have been sent to private garages, and the Darracqs have gone back to their shed on the pier.

DOUGLAS, Wednesday, 10 a.m.

No official times are or will be available until the Race Committee return to town. Great discontent exists in consequence, and complaints are universal at this treatment of the Press and the competitors. Jarrott had very bad luck. His first speed was unusable, and he started on second. He had to stop a long time at Ramsey to repair two punctures and to put in new inlet valve and sparking plug. The times for four circuits taken at Ramsey control were :—Stocks, 5 h. 7 min. ; Earp, 6 h. 2 min. ; Edge, 5 h. 7 min. ; and Jarrott, 5 h. 31 min.

The morning has opened gloriously for the Ramsey hill-climb, and yesterday's racers appear fit and well for the second event. Hemery and Edmond have returned to England, and it must be confessed no one is hurt at their disappearance from the scene of yesterday's contest.

THE HILL-CLIMBING TEST.

[BY TELEGRAPH.]

RAMSEY, Wednesday night.

A great assembly of motorists appeared at the luncheon hour at the Mitre Hotel, Ramsey, to-day, the company including Lord Raglan, the Governor of the Island. Several cars were drawn up in the Court House opp site, the space in front of the Hotel being roped off, to the amusement of the visitors. The hill at Port-E-Vullen where the climb is being held is situated in a most delightful locality. From the finishing point looking towards the beginning the lovely bay of Ramsey, nestling under a great hill, can be seen. At the back Snaefell looms grandly above the range of lesser mountains. The sun shines resplendently over the scene, a bustling wind having a cooling influence. The times are being taken over half a mile, including some awkward turns. Messrs. Sturmey, Straight, Woollen and Urry are the timekeepers.

The road is in fair condition, but towards the end of the course is somewhat worn, and at about twenty yards after the finish a dozen yards or so of loose stones threaten the tyres. After each contestant has a trial run three trips are taken, Stocks quietly coasting, the others, however, riding gamely. Some surprise is expressed at the absence of Jarrott. The three Darracqs are of course unexpected, and no one marks their absence. On the first of the timed runs Stocks seems very slow, Hargreaves being decidedly faster. Earp, who follows, warms to his work, but Edge provides the first real sensation, rushing up the hill in grand style—decidedly the best of the round. Girling, too, bends well to the machine, and Bianchi's crouching posture helps to distinguish Jarrott's car. On the second round Stocks again seems the slowest of the contingent, and Hargreaves is slower than on the first trip. Earp improves ; there is little difference among the others. At the end Earl Russell gives the official figures, which confirm the impressions already written, and provide quite a novelty, viz., the issue of official returns without demur. Until now, every difficulty has been placed in the way of the Press, but reasonable counsels have prevailed to-day, and the times for the half-mile are as follows :—First round, Stocks, 58 1-5 sec. ; Hargreaves, 50 2-5 sec. ; Earp, 44 2-5 sec. ; Edge, 38 2-5 sec. ; Girling, 44 1-5 sec. ; Jarrott, 47 2-5 sec. ; and Muir, 50 1-5 sec. Second round: Stocks, 57 1-5 sec. ; Hargreaves, 52 sec. ; Earp, 42 4-5 sec. ; Edge, 39 sec. ; Girling, 44 3-5 sec. ; Jarrott, 48 1-5 sec. ; and Muir, 51 2-5 sec.

Digitized by Google

The times in the third round in the hill climb were:—Stocks, 55 1-5 secs.; Hargreaves, 51 secs.; Earp, 43 4-5 secs.; Edge, 39 4-5 secs.; Girling, 43 3-5 secs.; Jarrott, 51 3-5 secs.; Muir, 50 4-5 secs. Edge, Earp, Girling, and Muir rode uniformly well, Edge's 38 2-5 sec. being a good speed, considering the road. After the event the spectators went their way to the electric tramcars, where we saw a crowd for the first time this week. Looking at the results so far, great satisfaction is felt at the advance made by Girling in connection with big races. His lengthening experience is enabling him to hold his own with Edge and others of that calibre. Earp, too, has suddenly rushed into fame. Hitherto known only as a driver of Napiers, he has by his form to-day, as well as by his smart driving yesterday, proved his worth. Girling's mechanician is a draughtsman in the Wolseley works, and has ably seconded his driver's efforts. At the Bungalow yesterday a new subway under the electric tram line was cut to enable people to cross the course during the race. To-night the Governor and competitors dine with the A.C.G.B I. at Castle Mona Hotel. The fastest speeds on the half-mile between Ballaugh and Ramsey yesterday were made by Edge, the times for his five rounds being 21 1-5 secs., 24 4-5 secs., 23 1-5 secs., 25 secs., 24 1-5 secs. Jarrott, who will be in France on Sunday practising for the French races, had difficulty with his gears. Two hundred tyres were held in readiness for repairs on the day of the race—forty at each control. An unfortunate accident occurred on Wednesday after the hill-climbing contest; a 12-h.p. Wolseley car, acting as tender for the racing cars, in taking a corner about three miles from Ramsey, had one of its tyres torn off. The wheel collapsed, and the car turned turtle, throwing out the passengers. The driver had a miraculous escape. All the passengers were badly shaken, while one suffered contusion of the face; he was unconscious for a time, and was taken to the hospital. In Tuesday's race Jarrott covered the circuit in 1 h. 16 min.

MANXLAND ECHOES.

Altogether about sixty automobiles have been in the island, including half-a-dozen motor-bicycles, one ridden by a lady, whose appearance in the streets has been a cause of much discussion among the native women.

Automobilists and members of the House of Keys met at a dinner on Wednesday evening at the Castle Mona Hotel, Douglas.

The proclamation of the Act enabling the motor-car races to be held was an important event on Tynwald Hill. For the first time in the history of that ancient ceremony motor-cars were employed, the Lieut.-General being driven in Mr. J. W. Orde's car, and many motorists being present. The following is the text of the Act:—

SLATTYSYN RAAD MOOAR GREIEYN EDDRYM NUY CHEEAD YEIG AS KIARE (1904).

T'an Slattys shoh kiarail chur pooar jeh raceyn lesh greieyn eddrym.

Ta'n chiedoo ayrn harey dy vod Boayrd y Raad Mooar hirrey liorish oardyr hoilshaghey dy vod raad carjin erbee ve ymmydagh son raceyn lesh greieyn eddrym choud as un laa as nagh bee ny smoo ny ny three laaghyn ayns y vlein.

WHEN THE WAY IS WET.

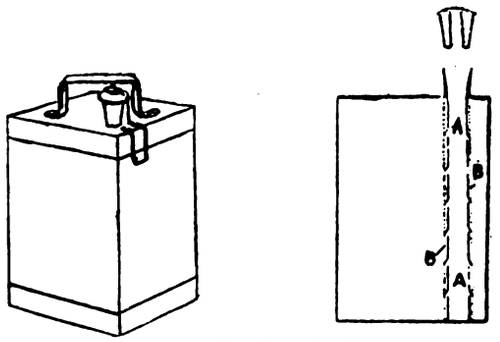
THOUGH it is quite possible to drive an open car through the rain for hours, and for the driver, when properly clothed, to remain perfectly dry and comparatively comfortable, still there are not very many owners of open cars so enthusiastic to start out in a heavy downpour, even when thoroughly provided with rain-resisting garments. This is an argument in favour of covered cars; though by this is not meant cars with fixed roofs or detachable brougham bodies so much as vehicles provided with hoods and hinged screens. With a car thus fitted, it is possible to drive in the worst weather without discomfort. Not only are the occupants protected from the rain, but, as the sides of the car are open, they are able at the same time to enjoy fresh air.

There is nothing more invigorating than a drive on a pouring wet day with a car equipped in this manner, remarks a writer in the "Automobile Magazine," as the driver and his companion are completely protected, and are able to obtain the full benefit of a change of scene and the exhilaration of the air of the open country without exposure. There is a particular satisfaction, too, in being able to use the car when practically all other forms of outdoor amusement are impossible except under great discomfort. Of course, the glass front is not satisfactory when covered with rain at night; but in the daytime it is perfectly easy to see through it, and there are no objections to its use; while, even at night, spectacled drivers see as well driving behind a wet screen, if not better, than with rain-spattered spectacles. The wet, while it may obscure the screen to some extent, does not affect the focus; but every wearer of glasses is painfully aware of the fact that he is practically blinded by rain, owing to the drops which remain on his glasses altering focus to a painfully aberrating extent. So long as the mechanism of the car is properly protected it will come to no harm from a long drive in heavy rain; and even in the case of absolutely unprotected chains they are not hurt so long as they are kept well lubricated. If there is not an opportunity to clean them immediately after the drive, they should be plentifully oiled when the car is put away. This will prevent rust, and they can be attended to at leisure, when time and opportunity permit of doing so.

DURING the recent visit of the King to Dublin the roads in Phœnix Park and from Naas to Punchestown were sprinkled with Westrumite with satisfactory results.

THE French Automobile Club has decided to close the eliminating course in the Ardennes to racing cars after Monday next, in order to allow the necessary road rolling to be done.

THE first meeting of the Aero Club for the present season was held on Saturday last at the Crystal Palace, when a very successful ascent was made by the "Graphic." The balloon, in which were Mr. R. K. Micklethwaite, Mr. C. Matterson, and Mr. Percival Spencer, made an excellent trip, and landed at Appledore, in Kent.



AT a meeting of the Northumberland County Council last week the County Surveyor, reporting on the traffic of motor vehicles, suggested that every road, to carry the traffic, must be provided with a foundation formed of material as hard as the road metal upon the surface, the vehicles should carry not exceeding six tons per axle, the diameter of the wheels should be increased, and the speed limit should be eight miles an hour. The width of the wheels should be not less than six inches.

UNITED MOTOR INDUSTRIES, LTD., have sent us a copy of a circular they have issued giving a number of useful hints as to the fixing and adjustment of the Cremorne petrol or paraffin automatic carburettor. for which they are the sole selling agents. The carburettor, which is stated to be giving very good results with paraffin in practical working, is made in three sizes, suitable respectively for 3, 7, and 15-h.p. single cylinder cars, the same sizes being suitable for 5, 12, and 24-h.p. double cylinder cars, and the latter two for 16 and 30-h.p. 4-cylinder vehicles.

SAFETY WITH PETROL.

ON Thursday afternoon last week an interesting demonstration of a new safety petrol can, which the Non-explosive Safety Device Company, Limited, are introducing into this country, was given at the Cadogan Garage, Chelsea. The main principle of the invention is applicable to lamps, barrels, petrol cans and tanks, and everything in which spirit of an inflammable character is stored. Fig. 1 illustrates the arrangement as fitted to an ordinary two-gallon petrol car. A pipe A, pierced with holes, extends from the mouth to the

Figs. 1 and 2.—The Non-Explosible Petrol Case.

bottom of the can or barrel. Round the pipe A is a tube B of fine wire gauze. The idea adopted is that of the Davy miner's lamp, no flame being able to penetrate through the gauze to the petrol in the can and cause an explosion. Another feature of the patent is to be found in the cork or plug. The latter is hollow, and is closed by a brass cap, held in place by a solder which melts at a temperature of less than 70 degs. Celcius. Thus, should the building in which petrol in these cans was stored catch fire, the heat would melt the solder and loosen the cap, and so allow any gas generated from the petrol to pass away before it could ignite or cause the can to explode.

There is no doubt as to the effective nature of the protection thus afforded. A petrol can fitted with the invention was dipped

Fig. 3.—Testing a "Nonex" Drum filled with 10 gallons of Petrol.

in petrol, which was ignited. With flame all round, the can was successfully filled with spirit from another small can. The second demonstration was that of applying a light to a two gallon petrol tin fitted with the device, and to another without it, both being filled with hydrogen gas. In the first case the gas merely ignited and burnt slowly out, while in the second the can immediately burst with a loud report. Finally we had a display which seemed to conclusively prove that the company have a patent which is calculated to give safety to all vessels in which inflammable spirit is kept or stored. A ten gallon metal cask was reared on a light wooden structure, and filled with petrol, a quantity being also poured over the exterior. The plug having been applied, the wood was ignited. As the heat became more intense the spectators would not have been surprised to have heard an explosion; instead of that, however, the plug was merely blown into the air, falling within a few feet of the cask. The contents then flared up, the flame ascending in a candle light form. By the application of a cloth the fire was easily put out. There is no doubt that the application of the idea to petrol cans and tanks will materially add to the safety of the automobile without increasing the cost to any great extent. We are informed that the device can be fitted as well to the petrol tanks on motor-cars and cycles as to the ordinary two-gallon cans.

MOTOR-CYCLING NEWS.

THE Coventry Motor Cycle Club has just been formed by a number of enthusiastic motor-cyclists in the Midlands.

A SINGER motor-bicycle has made its way into East Griqualand, Africa. The owner, who is a member of the Government boring operation staff at Matatiele, writes that the machine has carried him through Kaffirland and East Griqualand, and that he is now using it on the border of Basutoland.

THE combined motor-cycle run to Great Yarmouth which is being organised for Saturday, the 28th inst., promises to be a great success, the following clubs having promised to support it:—Motor Cycling Club, Thames Valley Motor Club, Hertford Automobile Club, and the Peterborough Motor Club. The route proposed is as follows:—Meet at the Salisbury, High Barnet, 10 a.m., then via Hatfield, Hertford, Ware, Puckeridge, Barkway, Pampasford Station, Newmarket (lunch), Bury St. Edmunds, Harleston, Beccles, Great Yarmouth (Queen's Hotel). Returning on Sunday as follows:—Ipswich, Colchester, Chelmsford, Dunmow, Bishops Stortford, and Ware.

THE first round of an interesting motor-cycle trial organised by the Peterborough and District Motor Club took place on Thursday, the 5th inst. The course was from Peterborough to the top of Cross o'-Cliffe Hill, south of Lincoln, via Market Deeping, Folkingham, Sleaford, and main road to Lincoln, and returning to Peterborough the same way, the distance being 100 miles. The conditions of the run were that competitors should only be allowed to dismount at the turning point and for congested traffic. No adjustment to the machines, other than could be done while riding was permitted, and the speed limit did not average more than twenty miles an hour or less than twelve. Delightful weather favoured the event, and the roads were in splendid condition. There were fifteen entries and thirteen starters. Of the latter, seven completed the distance in accordance with the conditions and thus qualified for the second round. These were:—T. S. Rickman, 2½-h.p. Bradbury; P. Mays, 2¾-h.p. Vinco-Minerva, P. R. Heighton, 2¾-h.p. Vinco-Minerva; B. Gibson, 2¾-h.p. Vinco-Minerva; T. Woodhead, 2¾-h.p. Bat; B. C. Holmes, 3½-h.p. Vinco-Minerva; and E. A. V. Sturton, 2½-h.p. Vinco-Minerva. The other competitors failed to finish, chiefly on account of puncture troubles. The prizes offered in connection with the trial include a handsome silver cup to the first, gold medal to the second, and a silver medal with gold centre to the third. Certificates will also be awarded to those who complete the hundred miles non-stop.

THE municipal authorities of Grahamstown, South Africa, have issued a regulation to the effect that no person when travelling on horseback, or by vehicle of any description other than cycle, motor-car, or steam traction engine, upon any public street within the Municipality, not exceeding 30 feet in width, including the side walks, shall for a distance of at least 30 feet before entering, and for the same distance on leaving any street, travel at a speed greater than four miles an hour.

CONTINENTAL NOTES.

The German Gordon Bennett Programme.

The German Automobile Club has issued the following programme for the Gordon Bennett week :—

Thursday, June 16th.—Weighing of racing cars. Evening reception at Kurhaus, Homburg.
Friday, June 17th.—Gordon Bennett Race.
Saturday, June 18th.—Touring excursion on the Gordon Bennett course. Evening dinner at the Kurhaus, Homburg.
Sunday, June 19th.—Race Meeting at Frankfurt-am-Main.
Monday, June 20th.—International Automobile Congress.
Tuesday, June 21st.—Competition for Appearance in the Kurpark. Flower Corso.

There has also been issued a programme of festivities at the Kurhaus in Homburg, from June 12th to 23rd. It includes concerts, theatrical performance, firework displays, and other fetes.

◆ ◆ ◆

Preparing the Course.

Operations are busily in hand at various points of the course in preparation for the great day which is rapidly approaching. As now decided, there will be "neutralisations" on the course at Mesingen, Weilburg, Limburg, Idstein, Konigstein, Oberursel and Homburg, equal altogether to 43 minutes. Thus for the four rounds there will be altogether three hours lost in these neutralisations. The German Wireless Telegraphy Co. is arranging to establish three wireless telegraph stations on the course—at Saalburg, Gratenwiesbach and Neuhof.

◆ ◆ ◆

The French Eliminating Test.

In France all attention is now centred on the eliminating contest for the French Gordon Bennett team, which is to be decided on the 20th inst. Many of the racers are now careering daily over the course in the Argonne. The Turcat-Mery cars, rated at 80-h.p., have been completed. On the level a speed equal to eighty-eight miles an hour is said to have been attained. The Hotchkiss racers have four-cylinder engines stated to develop 115-h.p. at a speed of 1,200 revolutions per minute. The cylinders are 175 mm. bore by 180 mm. stroke. The start has been fixed for five o'clock in the morning, "whatever be the weather." Although the race is expected to be over by 2 p.m., the result will probably not be known before 6 p.m. Seven official timekeepers have been appointed in connection with the tests, and a trial of the arrangements will be made on the course the day preceding the race. The neutralizations so far fixed are —Vouziers ten minutes, Le Chesne five minutes, Rethel ten minutes, and the Novy level crossing a stop of thirty seconds. No cars other than the racers will be allowed on the course. Of the twenty-nine cars in the test, twenty-two will be driven by Frenchmen, two by Belgians, and five by Englishmen, the latter being Messrs. H. Farman, Jarrott, Stead, Baron de Forest and A. Burton.

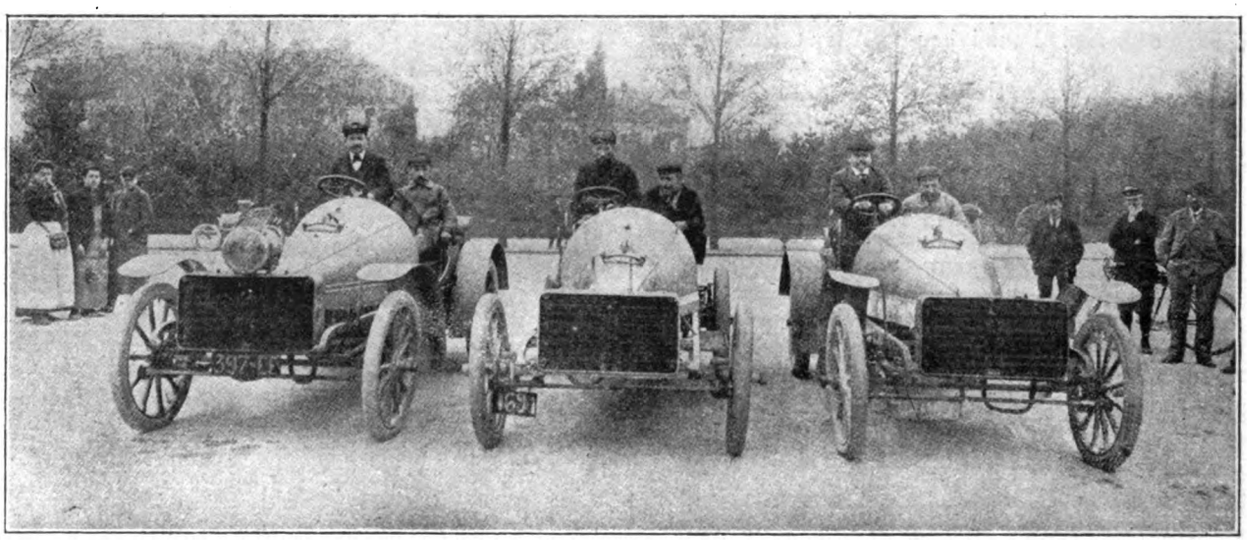
◆ ◆ ◆

The Order of Starting.

The following is the order in which the competitors will start :—

1. Gabriel (De Dietrich).
2. Baras (Darracq).
3. Hanriot (Bayard-Clement).
4. P. de Crawhez (Hotchkiss).
5. L. Thery (Georges Richard-Brasier).
6. Le Blon (Gardner-Serpollet).
7. Salleron (Mors).
8. H. Farman (Panhard).
9. Rigolly (Gobron-Brillié).
10. H. Rougier (Turcat-Mery).
11. Jarrott (De Dietrich).
12. Beconnais (Darracq).
13. Guders (Bayard-Clement).
14. Achille Fournier (Hotchkiss).
15. Caillois (Georges Richard-Brasier).
16. Chanliaud (Gardner-Serpollet).
17. A. Leger (Mors).
18. Teste (Panhard).
19. Duray (Gobron-Brillié).
20. De la Touloubre (Turcat-Mery).
21. Baron de Forest (De Dietrich).
22. Wagner (Darracq).
23. A. Clement (Bayard-Clement).
24. Amblard (Hotchkiss).
25. Stead (Georges Richard-Brasier).
26. Pelser (Gardner-Serpollet).
27. Lavergne (Mors).
28. Tart (Panhard).
29. Alexander Burton (Gobron-Brillié).

◆ ◆ ◆



Mails by Motor-Car.

THE French Post Office authorities are inviting tenders for the conveyance of the mails between Messac and Carentoir (Ille-et-Vilaine) and between Redon and Guer (Morbihan) by motor-car.

◆ ◆ ◆

The Calais-Dover Motor-Boat Race.

As already mentioned in these notes, the Calais-Dover motor-boat race will be held on Monday, the 8th August, starting at 10 a.m. The race, which will be open to boats of all nationalities, of any size, and of any system of motive power, will be held under the rules of the Automobile Club de France, and at the same time a race will be held for the Recope Cup for boats using ordinary petroleum, and for the Quinones de Leon Cup for boats using denaturised alcohol. Entries must be received before the 15th July at the automobile clubs of the various countries. The entrance fee is 100 francs for boats up to 8 metres long, and 200 francs for boats of greater length. It should be noticed that under the regulations of the French club boats below eight metres must carry three life buoys and boats over eight metres four. Every person taking part in a race will have to wear a life belt, the boats must be unsinkable, and every boat up to twelve metres must carry an anchor weighing forty kilos with a length of chain of forty metres ; and above twelve metres, the anchor must weigh sixty kilos with sixty metres of chain. Side lights, a chart and compass must also be carried. Boats taking part in the race must be presented at Calais

The Three Serpollet Steam Cars which will compete in the French Eliminating Trials next week.

Digitized by Google

on Thursday, 4th August, at latest, and from Thursday to Saturday may be subjected to runs out to sea. On Sunday, the 7th August, all the boats taking part in the race will be exhibited and boats which are not present will not be allowed to take part in the race.

◆ ◆ ◆

The 1905 Nice Week.

At a meeting of the Committee of the Nice Automobile Club last week it was decided to hold the 1905 Nice week from the 5th to the 19th February next.

◆ ◆ ◆

The Spa Week.

The Automobile Club of Spa has issued the following programme of the automobile meeting to be held from the 26th July to the 1st August next :—

Tuesday, July 26th.—Arrival and weighing of cars.
Wednesday, July 27th.—9 a.m., Spa-Malchamps Hill climb ; 2 p.m., one mile hill climb for the Spa Cup, standing start.
Thursday, July 28th.—9 a.m., start of 100 kilometre trial of motor-cycles.
Friday, July 29th.—10 a.m., start of 120 kilometre run for touring cars.
Saturday, July 30th.—10 a.m., start of motor-car balloon chase ; 4 p.m., opening of exhibition.
Monday, August 1st.—2 p.m., driving competition ; 6 p.m., distribution of prizes and banquet.

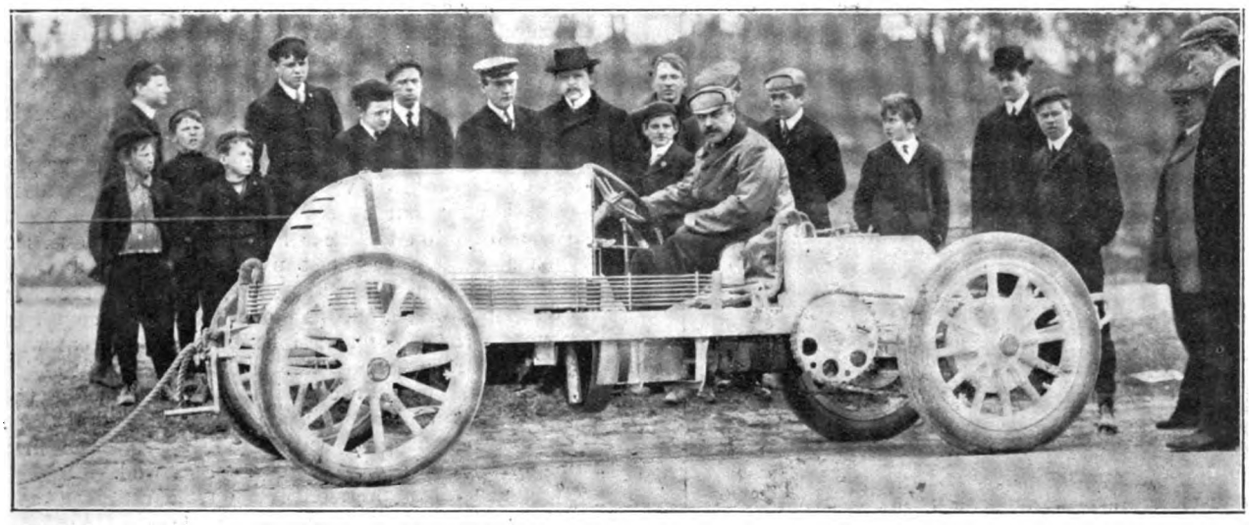
et d'Automobiles of Brussels is building two 100-h.p. Baudouin racing cars for this year's Circuit.

◆ ◆ ◆

Motor Wagons in Brussels.

It is reported that the large co-operative concern in Brussels known as "La Maison du Peuple" intends to adopt motor-lorries in place of its present horse-drawn vehicles

◆ ◆ ◆



Speed Trials and Racing at Arras.

So far only four motor-cars and three cycles have been received for the speed trials and races to be held at Arras from the 25th to the 28th inst. The programme given in the *Journal* of the 30th ult. has been changed in so far that the five kilometre race is to be run off on the 26th inst. and the kilometre hill-climb on the 27th inst.

◆ ◆ ◆

The Touraine Touring Competition.

The touring competition which the Automobile Club of Touraine is holding this week has brought forward a fair number of competitors. The competition is over a total distance of about three hundred miles, and will be run in two days, that is to say, on the 13th and 14th inst., round about the city of Tours. The other days will be occupied with the weighing and the exhibiting of the cars. There will be one motor-cycle class and three categories of cars, namely : (1) Cars whose chassis cost not more than £240, (2) cars whose chassis cost between £240 and £680, (3) cars whose chassis cost more than £680.

Mr. H. P. Bowden's 60-h.p. Mercedes, which tied with a 40-h.p. Georges Richard for the first place in the recent Hill-Climbing Competition at Boston, U.S.A.

The Federation of French Automobile Clubs.

The movement to establish a federation of French automobile clubs, proposed by Prince d'Arenberg, is making good progress. Of the thirty provincial clubs in the country, twenty-two have agreed to join in the scheme.

◆ ◆ ◆

The French Carburettor Competition.

At the request of several of the competitors, the start of the carburettor tests which are being organised by the A.C.F. has been postponed from the 16th to the 24th inst. The chief object of the trials is to ascertain with different devices the power developed at various speeds and the consumption in litres per kilowatt hour. The trials will be made upon a Gillet-Forest single cylinder motor, running normally at 850 revolutions per minute, and the carburettors will be placed in three classes, those designed for a particular engine, those intended for a particular fuel, and thirdly those which claim to be adaptable without restriction in these respects.

◆ ◆ ◆

The Circuit des Ardennes.

The Automobile Club of Namur and Luxembourg has decided to erect a covered stand at Bastogne to enable its members and their friends to witness the Circuit des Ardennes race. It is announced that the Societe de Construction Mecanique

◆ ◆ ◆

A Military Motor-Cycle Relay Ride in France.

Following the example set by Austria, France is now to have a military motor-cycle relay ride, "L'Auto" having undertaken its organisation. A sealed despatch will be carried by ten motor-cycle riders from Brest to Belfort, a distance of about 1,000 kilometres. The riders, who will be ten in number, will follow the route given below :—Brest, Rennes, Laval, Alençon, Dreux, Paris, Meaux, Epernay, Rheims, Bar-le-Duc, Nancy, and Belfort. The course will be divided into ten sections, each about 100 kilometres long, and each rider when he arrives at the end of his section will hand over the despatch to another rider, until it is finally in the hands of the rider who will cover the section between Nancy and Belfort, the termination of the ride. It is hoped to have ten different makes of motor-cycles in the trial. One of the regulations is that the machines which are used must be of the ordinary touring type, and the weight must not exceed 110 lbs.

THE Board of Public Safety of Cleveland, O., U.S.A., is considering a proposal that several motor-bicycles be purchased for the use of the policemen who are seeking to suppress automobile scorchers.

THE SIDE-SLIP TRIALS.

THE CONCLUDING TESTS.

THE last event in the Side-slip Trials took place on Saturday, at the Locomobile Garage, South Kensington, where a greasy track had been laid for the holding of the skidding tests. This consisted of a space about 15 ft. to 20 ft. wide and 35 ft. to 40 ft. long, in which the concrete floor had been covered with a mixture of Thames mud and soft soap, which after careful tests had been found the best lubricant obtainable, and, indeed, its anti-friction qualities left little to be desired. It had one small idiosyncrasy—namely, that it could only be satisfactorily spread by the human foot—suitably protected, of course—as brooms and squeegees simply rolled it up into lumps; and the proceedings were therefore diversified by step-dances from the secretary and other volunteers engaged in obliterating the traces left by each car, to prepare for the next.

The cars entered by the doors at one end, where an 88 ft. length had been marked off from the commencement of the track, by which their speed on entering the latter could be timed; while at the other end, and just in front of a small glazed compartment forming a clerk's office, was scattered a layer of gravel to facilitate turning or pulling up for those cars for which the grease was too much. About 10.15 the proceedings

A Car Starting on the Slippery Track.

Photo by] *[Argent Archer.*

were commenced by the running of the Club car over the trial patch, which proved sufficiently effective to make turning quite impossible till the car had reached the gravel at the further end. The cars were then sent over the grease in order, with instructions to make a sharp turn to the left when well in the middle of the patch; but during these tests, having no device to prevent skidding of the front wheels, the results were rather monotonously uniform. Each car steered to the left, but the front wheels failing to grip, continued its straight course till the front wheels struck the gravel at the end, and then came round sharply, the short interval between the front and hind wheels reaching the gravel giving little opportunity of seeing, at this stage, how far the back wheels travelled sideways.

The turn of the motor-bicycles came next, the Wilkinson-treaded machine coming along boldly, but the attempt to turn resulted in a "cropper," and a plucky remount for a second trial met with the same result. The Parsons followed, and escaped a fall, but only by making no attempt to turn. The Bates and the Empire then tried, but with no better success, the latter coming down heavily and bending one of his anti-skid legs. It was seen by this time that the course was too risky for bicycles, devices, which undoubtedly give additional security on ordinary bad roads, being utterly useless on such grease as this.

After this came alternate stopping, reversing, and turning tests, the turns being taken somewhat slower. No. 1.—Butler, pulled up moderately well, skidding somewhat, but did not get round the turn till reaching the gravel. No. 2.—Cavendish, was, of course, not helped in pulling up by his device—a mechanical one—and skidded fairly straight to the gravel. No. 3.—Hunt, behaved in much the same way, as did also No. 5—Rourke; the latter doing a worse side-slip when pulling up, and all three spinning their wheels more or less in starting, stopping and reversing, as was only to be expected with plain tyres. No. 6.—Nicholson, created a diversion by failing to pull up, and colliding with the small glazed office before mentioned. No. 7.—Vivian, came up slowly, and spun its wheels round vigorously in reversing and starting, failing also to turn without the assistance of the gravel, skidding considerably. No. 8.—Williamson, stopped rather better, but spun its wheels somewhat in starting, and skidded to the gravel before turning. No. 11.—Sainsbury, was not much assisted in stopping by its device. It took the turn rather better by turning early and not too fast, but skidded nevertheless. No. 12.—L'Empereur, stopped and started remarkably well, but having the device on the back only, could not turn better than before. It did not, however, skid sideways in turning. No. 14.—Parsons, also pulled up, reversed, and started well, but turned no better for the same reason. No. 15.—Billet, did well, though not quite so well as the last two, and also could not quite manage to turn on the grease.

A further series of tests was then made with the Billet, L'Empereur, Parsons, and Wilkinson devices, in which one or more of the front wheels of the cars employed was armed with a non skid, with the result that the first really successful turns on the grease were made, the Parsons, with all four wheels armed, leading off with a turn of about fourteen-feet radius at a fair pace, right on the greasy patch, the front wheels gripping well, and the rear skidding very little. The L'Empereur tried next, and not having four covers available, put one on the off front, and the other on the near hind wheel. With this the turn was managed at a very fast pace, coming round well, with a considerable, but not unmanageable, side-slip of the rear wheels. The Wolseley-Wilkinson, with one tread on front and two on back wheels, came round all right, but with a great wag of her tail. The Parsons was next tried with one front and one back wheel armed, and turned with little slip, while the Billet had two trials under the same conditions, skidding straight before getting a grip with front wheels the first time; then, at a slower pace, taking the turn well.

The general impression left on the observer, at least as regards cars, is that while most of the devices are distinctly protective under ordinary bad road conditions, the only ones that give security under the very worst circumstances (which must include somewhat reckless driving) are those of the type of the L'Empereur and Parsons, and, to a less degree, the Billet, and, perhaps, the Wilkinson, if not too much worn; but for this they must be on all four wheels. If on back wheels only, pulling up on grease is facilitated, but not turning if surface is too bad for front wheels to grip; this, however, is not often the case with ordinary care. There are many other considerations, though, such as cost, upkeep, ease of attachment, and wear on tyres, that prevent one's choice being decided by this conclusion alone, and the final verdict, in which all the various factors are taken into account, will be awaited with interest.

MANY alterations are in hand for the quicker dispatch of the business connected with the Metropolitan Police. Orders have recently been given for several new motor-cars for the district superintendents, in place of the horse and dogcart now in use. Already there are six cars at Scotland Yard for use on urgent business.

IN fining a motorist for driving his car to the danger of the public at Surbiton, the chairman of the Kingston-on-Thames county justices (Mr. W. Y. Cockburn) said "It appears to those living in this neighbourhood that motorists are trying to drive horse traffic off the roads, and endeavouring to monopolise them, irrespective of the inconvenience they may cause."

HERE AND THERE.

TUESDAY last was a Bank Holiday in the Isle of Man.

MRS. ROBERT LOUIS STEVENSON, the widow of the famous novelist, has purchased a White steam car.

APPLICATION has been made to the Secretary for Scotland for the prohibition of motor-cars on the roads of Arran, N.B.

THE Locomobile Company of Great Britain, Limited, inform us that they have just received one of the latest pattern Spyker cars, for which they are now the British agents.

THE Iowa Senate has passed the bill requiring the registration of motor-cars with the Secretary of State and fixing the speed limit at 20 miles per hour in the open country, 10 miles in crowded cities, and 15 miles in towns and villages.

THE Stern-Sonneborn Oil Company have made arrangements whereby any motor-car owner can have a supply of their Motor Sternoline lubricant for racing cars. This will be delivered carriage paid without extra charge to any address in Germany, France, or Belgium during the forthcoming motor-races.

THE Mercedes Hotel has just been opened in the Rue de Presbourg, Paris.

MESSRS. CARLESS, CAPEL, AND LEONARD notify us that they have reduced the price of the standard petrol 1d. per gallon.

THE committee of the Western Section of the Scottish Automobile Club have received consent from the road authorities of the Upper Ward Committee of the Renfrewshire County Council to conduct experiments with oil, Westrumite, and other substances on roads in the vicinity of Glasgow.

THE Acme Motor Company, Limited, has been registered with a capital of £1,000 to acquire the business carried on by Mr. G. E. Pearce at 4, Belle Vue Road, Wandsworth Common, S.W., as the Acme Motor Company, and to carry on the business of manufacturers of and dealers in motors and motor-cycles, etc.

THE Corporation of London have made application to the Local Government Board for a regulation putting in force within the City the provisions of Sub-section 1 of Section 9 of the Motor Car Act, 1903, limiting the speed of motor-cars in their district to ten miles an hour. Objections may be sent to the Local Government Board up to the 16th inst.

The Motor-Cycling Club's Run to Market Harborough. Mr. E. Kennard meeting the Members at Newport Pagnell.

THE Committee of the Yorkshire Automobile Club are preparing to make arrangements for garage in the various towns in the country, and to this end are desirous of information, applications and recommendations respecting various garages, so that a full list may be made out for the convenience of motorists.

THE Great Western Railway Company is credited with the intention of starting a motor-car service between Saltash and Callington. The other day a trial trip was run between the two places to obtain some idea as to the time-table that will be required, and it is hoped that a regular service will be inaugurated at the beginning of June.

MESSRS. J. H. BUTCHER AND CO., who make a speciality of transfer printing, have just issued a new series of transfers suitable for identification marks for motor-cars and cycles, which should prove useful to motor agents. The transfers are made up in sheets containing complete sets of the alphabet, and a range of figures from 0 to 9, together with a number of duplicate letters and hyphens. They are printed in white to regulation size, so that any mark can be quickly made up from the sheet and applied to a panel of the car.

AT a meeting of the Racing Board of the American Automobile Association held on the 18th ult. a resolution was adopted reinstating Barney Oldfield, who was disqualified for taking part in unsanctioned competitions, the reinstatement to be preceded by the payment of a fine of £20. The fine was promptly paid, and Oldfield is again eligible for races.

AS mentioned in a recent issue, the Great North of Scotland Railway Company has started a public service of motor-omnibuses between Ballater and Braemar. The journey occupies an hour and a half. At present two services per day are being run in each direction. The vehicles are 16-h.p. Milnes-Daimlers with seating accommodation for sixteen inside passengers.

VOGT ENGINES, LIMITED, has been registered with a capital of £240,000 to acquire all the assets and undertaking of Vogt Motors, Limited, to turn to account the letters patent, inventions, rights, and interest of the said company, and to carry on in the United Kingdom or elsewhere the business of manufacturers of motors, traction and other engines, cycles, and carriages of all kinds. The registered office is at 56, Cannon Street, E.C.

THE London Fire Brigade has a first-aid motor appliance in active service.

AT a meeting of the Richmond Corporation on Tuesday it was resolved to ask the Board of Works to limit the speed of motor-cars in Richmond Park to ten miles an hour.

THE latest anti-skidding and puncture proof band for motor tyres to attract attention is the Durandal, of which an illustration is given herewith, and for which M. H. Cintrat, of Paris, has secured the British agency. It consists of a rubber band, the internal diameter of which is equal to that of the outside of the

cover it is to protect. To the band are attached a series of straps terminating in steel pieces which grip the rim of the tyre, as illustrated. The band itself is provided on the tread with a series of steel studs. The Durandal band is claimed to be most effective, both as to its anti-skidding and non-puncturing qualities.

THE Rapid Motor Vehicle Company, Limited, has been registered with a capital of £100 to carry on the business of manufacturers of and dealers in all kinds of motor and other carriages, cycles, &c.

THE question of the excessive speed of motor-cars in Hythe was again discussed by the Town Council last week. It was urged by several of the members that a speed limit should be fixed, and it was decided to communicate with the County Council to this effect.

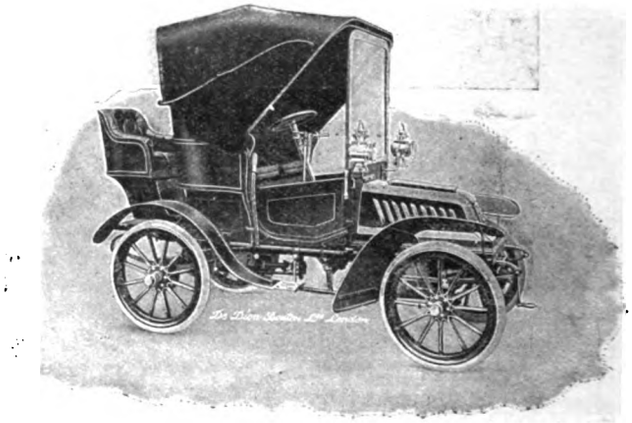
THE eleven racing cars entered by the various English makers for the Isle of Man Eliminating Trials for the right to represent Great Britain in the Gordon Bennett Race, and valued at £40,000, were insured with The Car and General Insurance Corporation, Limited, by the A.C.G.B.I. against fire for the above amount whilst in their possession.

IT is recommended that any British competitors proposing to enter for any of the events in the Calais-Dover motor-boat race in August next should secure an official certificate as to the size of the motor before it is finally put on board. This certificate, which will be accepted by the French Club, may be obtained on application to the official measurer of the A.C.G.B.I., Mr. J. A. Smith, of 47, Leadenhall Street, E.C.

AN injunction prohibiting the municipal authorities of Chicago from interfering with Mr. J. V. Edgerton, "or any other automobile owners similarly situated," has been issued by Judge Hanecy. The granting of the petition has a sweeping effect, as it allows disregard of the automobile ordinances by the 2,500 other owners and operators of motor-cars who may seek to take advantage of the writ. Both numbering and licensing ordinances are to be held in abeyance.

ON Friday, last week, Mr. George Iden, late works manager of the Motor Manufacturing Company, was the recipient of a presentation in the form of a handsome writing table and a framed photo of the offices and works staff. The presentation was made by Mr. B. K. Field, the present works manager, on behalf of the staff and employees. In additional proof of the high esteem in which Mr. Iden was held, quite 200 employees were present to wish him success in his future undertaking. Mr. Iden spoke of the many successes the M.M.C. cars had achieved during the six years he had been connected with the company, and also as to the gradual development of the motor industry.

A CINEMATOGRAPH film of the Pedrail engine in motion (the traction engine with feet, which has already been illustrated in the *Journal*) is now on view daily at the Polytechnic Institution, Regent Street, W., with "Our Navy."



THE West Riding authorities are proposing to purchase a motor-car, at a cost of £1,000, for their surveyor. It is said the use of one will enable him to keep a more constant and efficient control over the roads and bridges.

A 500 kilometre speed trial, with standing start and stopping finish, was held on Sunday last by the Antwerp Automobile Club, the winner being M. Elscamp, who on a "Metallurgique" car covered the distance in 55 secs.

THE Chief Constable of Eastbourne has submitted to the Watch Committee a schedule of roads in which it is suggested the Local Government Board should be asked to make regulations imposing a ten mile limit. At the meeting of the committee last week it was, however, decided "that the application to the Local Government Board to make the necessary regulations be deferred until the effect of the notice boards requesting motorists to drive slowly has been ascertained.

MESSRS. LOWE, BEVAN AND CO., Birmingham, have recently placed on the market two new special fittings for motor-cars. One consists of an ingenious arrangement for dust screens; the fitting is self-locking, the window is carried into the roof by slotted grooves on each side of the window frame. At the top of the grooves are cranked arms, and at the upper end of the crank is inserted a slot. The pins travelling in the side grooves are carried into these slots, and springs situated at the end of rods carrying the window force the pegs into the slots, and make a most secure fixing of the window in the roof. The arrangement is a very complete one, and well worth the attention of motor body builders who are fitting up cars with dust screens. The second production referred to is a new Cape cart hood fixing. In this, instead of the usual flat metal slats which are attached to the hoop sticks, oval tubes are employed. We may add that these fittings can be supplied alone or the Cape hood complete ready for fixing on to a car.

THE great advantage of motor-cars to doctors cannot be overestimated, as, apart from the question of economy, they overcome all possibility of delay in time of emergency. One of the most commendable features of the automobile is its readiness to respond to immediate action. Oftentimes the loss of a few

minutes would jeopardise the life of a patient, but with ready means at hand to start without delay at high speed the saving of time would be of incalculable benefit to the suffering one. That the utility of the motor-vehicle is being realised by doctors is evident from a perusal of the pamphlet entitled "Motor-Carriages for Medical Men" which has been issued by Messrs. De Dion Bouton, Ltd., and of which a copy has been sent us. The booklet gives in a collected form the experiences of a number of doctors with motor-cars, and a list of over 60 members of the medical profession who are using De Dion cars in their practice.

CORRESPONDENCE.

INCONSIDERATE DRIVING.

To the Editor of *The Motor-Car Journal*.

Sir,—The Committee of the Automobile Club have decided on measures in the carrying out of which they desire the co-operation of the public. The Committee are appealing to all drivers of motor vehicles to drive with consideration for other users of the highway, and are urging members of the Automobile Club to set an example by so driving their automobiles as to inconvenience as little as possible the public generally. The Committee of the Club feel sure that the members of the Club generally do not desire that any automobilist who may persist in driving his motor vehicle inconsiderately should be, or remain, a member of the Club. They therefore wish it to be understood that the Committee of the Club are resolutely setting their face against motor-cars being driven, not only at high speeds to the danger of the public, but also to the annoyance of other users of the highways of the United Kingdom, and deprecate the use thereon of cars intended to be driven at excessive speeds.

The Committee also realise that motor vehicles of low power are at times driven very improperly.

The public are provided by the Legislature with effective measures for bringing to justice drivers of motor vehicles which are driven at excessive speeds, or to the danger of the public, and it is therefore not necessary for the Club to invite the co-operation of the public in connection with these punishable offences.

The Committee, however, invite the public to draw attention (by letter addressed to the Club Secretary, Automobile Club, 119, Piccadilly, London, W., to flagrant offences by motor drivers against the laws of etiquette and good feeling which are well understood and generally observed by all classes of road users, and to such conduct as may, by causing unnecessary vexation and inconvenience to the public, prejudice the best interests of automobilism in this kingdom. If the offender be a member of the Automobile Club, he will be dealt with under Rule 63, which many require his resignation.

If the offender be not a member of the Automobile Club of Great Britain and Ireland, but be a member of an affiliated Club the complaint will be passed on to the Committee of that Club.—Yours truly,

H. C. L. Holden,
Chairman of the A.C.G.B.I. Club Committee.

STEAM CARS.

To the Editor of *The Motor-Car Journal*.

Sir,—Reading in one of the daily papers of a book bearing the title "English and American Steam Carriages and Traction Engines," in which Mr. William Fletcher states, being a firm believer of steam as a motive power for carriages, that every steam carriage which passes along the streets "justifies the confidence placed in it; and unless the objectionable features of the petrol carriage can be removed, it is bound to be driven from the road to give place to the less objectionable rival, the steam driven carriage of the day." I think a good many people can endorse what he says to be perfectly correct. I am more than surprised to think that English engineers have not given more attention to steam. I am aware there are several making steam carriages, but some I have seen are too heavy and clumsy looking, and much too complicated. The only steam carriage I know of as near perfection is the White, but to my mind it has two faults: first, the price is too exorbitant; second, it should be made to burn paraffin. I think there is a great demand for a good steam car not to exceed 15 cwt., and at a reasonable price.—Yours truly,

Lancelot.

BRAKES AND TYRES.

To the Editor of *The Motor-Car Journal*.

Sir,—Will any of your readers kindly advise me how I can make the foot brake of my 6-h.p. De Dion (engine at back of car) more powerful. At present it scarcely acts at all, the oil, I am told, from the gear case getting on to same.

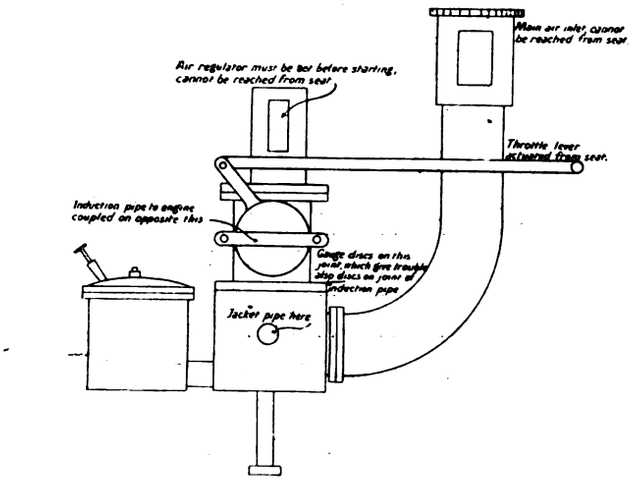
With reference to the Cambridge Autocar Company's letter in your issue of the 23rd ult. may I ask how the straps are fastened on, whether at the sides or across the inside of the cover; also how many would be required for a cover 700 by 85?—Yours truly,

Brake.

VARYING VALVE LIFT.

To the Editor of *The Motor-Car Journal*.

Sir,—I notice in the *Journal* of the 30th ult. a letter from "A. 2708," in which reference is made to our car, criticising the method of valve lift as described by you in a previous issue. I would like to draw the attention of your correspondent, and others who write in a similar strain, to the very able remarks of Mr. Dougald Clerk, also in the same issue, where he says "in many cases motors deviate somewhat from their understood requirements, generally not from ignorance on the part of the designers, but from some stern practical necessity." As the designer of the Utile car, I would like to point out that everthing has a reason for its construction; and what would, perhaps, appear at first sight somewhat out of place is not so when it is considered that our main object is to attain an essentially simple car. A motor-car must be considered as a whole, and certain details essential to our vehicle are quite out of place on another. Many parts have to be considered from different points of view, which do not occur to the casual observer, not only from a mechanical standpoint but also commercial, which affects the manufacturer and the purchaser. We do not claim to attain anything extraordinary with our car, but what we certainly do attain is a very fair result with a very small number of parts, and plenty of power in proportion to the weight, which means efficiency and minimum wear and tear.



The exhaust control under discussion is a very effectual and simple method of controlling a comparatively large cylinder and obtaining a very steady and expansive pressure when running light, owing to the cushioning action of the remaining products of combustion; in addition to which, ignition is very certain, compression being maintained. As to overheating, this I can say we have never experienced, as our valves give no trouble whatever, having a large water jacket and ample radiator. A temperature below that at which our engine works would be detrimental to its efficiency.—Yours truly,

P. G. Tacchi.

CARBURETTOR CONTROL.

To the Editor of *The Motor-Car Journal*.

Sir,—We have a Daimler car with two cylinder 9-h.p. Napier engine, the Longuemare carburettor of which is giving trouble in starting the engine. The motor will run all right for, say, a minute, then slows and stops; by manipulating the small air regulator it can be kept running until it is warmed up, when it goes well enough. At first I set this down to insufficient petrol, but found later on, taking the carburettor to pieces immediately after one of these stops, that the gauze discs between the engine pipe and the carburettor were solid with water. On wiping the water off and replacing, the engine would start readily enough, but stop in a minute, if left alone, through the same cause. The engine will not work until everything inside the bonnet is extremely hot—it will hardly work at all with the bonnet off. This water, I would say, is caused by condensation due to the rapid evaporation of the petrol. Is there any way of overcoming this nuisance, as it is

annoying to have to stand by and nurse the engine every time a start is made, especially when there is a crowd around?

The water cooling arrangement is simply a tank under the car and circulation by pump, and the water boils sometimes on a five-mile run; this is another nuisance. Would fitting a radiator in front of the bonnet have the effect of curing this? I would like to go thirty or forty miles without changing water. I enclose a sketch of carburettor. I omitted to say that the branch pipe off the exhaust to the carburettor jacket is quite free, as it gets warm, and can be felt blowing through. I should be glad if you or any reader could give a hint as to how the above faults could be remedied.—Yours truly,

Cycle Mechanic.

[In answer to "Cycle Mechanic's" query *re* carburettor trouble, we should strongly advise extending the main air pipe, so as to come in close connection with the exhaust pipe, in order to draw in hot air, which will most probably remedy the trouble of water on the gauze. But before doing this there would be no harm in trying the engine with the gauze removed, as the latter sometimes tends to act as a throttle, and numerous cars are daily running without the gauze.

Failing either of these giving the desired result, we should be inclined to think that the carburettor is too small for the size of engine. With regard to the water circulation, "Cycle Mechanic" would undoubtedly find the benefit of a radiator on the front of the car, and if a thoroughly efficient one be got the car would have no difficulty in running perhaps daily for a week without the water reqniring to be replenished.]

MOTOR VANS FOR TRINIDAD.

To the Editor of *The Motor-Car Journal*.

Sir,—Could you put me in the way to get detailed information concerning motor-vans? I contemplate running one as a tentative measure

Digitized by Google

in connection with one of our railway termini (at Trinidad). My idea is to have a van that can do a good twelve miles loaded, and the body so constructed that we can pack a load of ten to twelve passengers when we are not taking produce, *i.e.*, one trip we could run passengers and light luggage, and the next take up freight. The vehicle should have two removable benches running lengthways, and should be roughly constructed, no regard being paid to upholstery of any kind. As this would be an entirely new departure in our present methods of transport, I would like to ascertain whether any similar idea is being carried out in any of our tropical dependencies, and whether we would experience any technical difficulties in the working and upkeep of the machinery. I would like also to know which, for our climate and general conditions, is thought the best system of propulsion, steam, electricity (we have a power station), or petrol, etc. A rough idea of the cost of a car of the capacity mentioned would be useful to know. If you have any illustrations or literature that would assist us to determine, I would feel obliged if you would mail them on.—Yours truly,

H. D. FADELLE.

[We shall be glad to forward any lists of suitable vehicles sent us to our correspondent.—ED. *M.C.J.*]

COST OF OPERATION.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I see in the *Journal* you ask for the cost of operating cars. I therefore send mine, as it may interest your readers. I have omitted the first cost together with interest on same and depreciation, as that is the same for everyone. I have put a share of mechanic's wages, as I have two cars, etc., and I am my own driver. With regard to "Less railway fares saved," I have only put down those journeys which I should have had to have taken in any case. If the car continues as well as it has done during the first year, I shall have every reason to be pleased with it.—Yours truly,

EDWARD S. CHURCHILL.

14-h.p. Daimler car. First year's cost, etc., including tyres and spare parts :—

	£	s.	d.	
Insurance	13	4	0	
Licence	2	2	0	
Registration...	1	0	0	
Driver's licence	0	5	0	
Estimated share of mechanic ...	30	0	0	
Cost of petrol	16	2	4	229 galls. ·076 per mile.
Repairs to tyres (Collier's) ...	23	17	7	About 2d. per mile.
Repairs to car	1	7	3	
Lubricating oil	1	6	3	
Total	89	4	5	
Less railway fares saved	23	17	5	
Running cost	65	7	0	5·2 pence per mile.

Number of days car has been used, 124; miles run, 3,004; average run, 25 miles per day.

DECAUVILLE CARS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Replying to Mr. J. W. Hicks' enquiry in the *Journal* of the 30th ult. re Decauville 10-h.p. cars, I beg to inform him I have been driving a car of this type for the past two years. It has never given me a moment's trouble, and I believe I am right in stating there are several improvements on the present 10-h.p. car. I was so pleased with the 10-h.p. that I purchased last year a 20 h.p. Decauville. They are both in my possession at the present time, and I am not at all inclined to part with either.

I do not pretend they are so fast as some other cars, but thirty miles an hour for the 10-h.p. and over fifty for the 20-h.p. is not bad.—Yours truly,

E. H. SMITH. (MAJOR.)

A PROPOSED INSTITUTION OF AUTOMOBILE ENGINEERS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Some months ago you were kind enough to notice in your columns a circular which I was then placing before a considerable number of automobile engineers and other followers of the automobile movement. This circular sought opinions and criticisms as to certain suggestions dealing with (*i*) a proposed institution of automobile engineers, and (*ii*) a proposed scheme of automobile engineering education.

Out of a large number of replies received, some ninety per cent. were of a favourable nature; these, moreover, were remarkably unanimous upon the following points, viz. :—(*i*) That an institution of automobile engineers, following approximately the lines of the existing engineering institutions, should be formed. (*ii*) That the question of automobile engineering education should be postponed for the consideration of the Institution of Automobile Engineers, when formed. (*iii*) That only persons actually engaged in the designing and constructing of automobile machinery and vehicles should be eligible as members, (associate members, etc.) of the Institution; but that other persons connected with or interested in the construction, employment, etc., of automobiles, should be eligible as (say) associates of the Institution. (*iv*) That reports of meetings, contents of original papers discussed at meetings, and any other literary matter relating to the transactions of the Institution should be printed and distributed, free of charge, among the members, associates, etc., of the Institution. (*v*) That the Institution should consider the question of organising a testing department, for the purpose of conducting various official tests of automobile machinery and vehicles and of issuing certificates of the results obtained. This department would bear much the same relation to automobilism as Lloyd's does to shipping. (*vi*) That the Institution of Automobile Engineers should confine its attention to the strictly technical aspects of automobilism.

My friend Mr. T. M. Cairns has since carried out a similar "canvass" in Scotland, with much the same result. We propose to call a meeting in London, at an early date, for the purpose of submitting for discussion a scheme drawn up on the above lines. While desiring that such meeting should be as representative as possible, we find it very difficult to communicate directly with more than a limited number of automobilists. If, therefore, you could find a place for this (I fear lengthy) letter in your correspondence columns, it would be of very great assistance.—Yours truly,

JOHN F. MARSHALL, M.A.

ACETYLENE MOTORS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—Like your correspondent Mr. F. J. Spencer, I also have been anxious to learn whether acetylene gas could not be used as engine fuel. Noticing an article in one of the motor journals some months ago, I wrote to the French inventor, who has only just sent me his reply. Translating the same the reply would be as follows :—

"As you say in your letter, the burnt gas is odourless, vibration is practically nil, starting is instantaneous, and with the gas no breakdowns need be feared, as no carburettor is used, because the gas reaches the motor in a finished state. Instead of the carburettor there is a mixer of air and gas with accurate 'dosage.' I have made numerous experiments with a Buchet bicycle of 1¾-h.p. The consumption was one kilogram of carbide per 100 kilometres. The carbide is not in cartridges, but the commercial product in fifty to sixty millimetre pieces. The generator is automatic, more power is developed than with petrol, and the valves foul less."

The inventor refers to the advantage that lighting can also be had from the same source and that he is making similar experiments with another motor. He is anxious to develop the invention on this side of the Channel, and I shall gladly place anyone sufficiently interested into communication with the inventor.—Yours truly,

L. W. K. TRUBRIDGE.

THE MOTOR-VAN PARADE.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—In your article on the above in the last issue of the *Journal* it will probably strike some of your readers as strange that, although you mention two Milnes-Daimler vehicles belonging to the Midland Railway Company, these are not included in the list of those for which prizes have been awarded. These two lorries were not, however, eligible to enter for the competition proper, as they had only just been handed over by the makers.—Yours truly,

HY. FOWLER.

CARS FOR DEVONSHIRE.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I purchased some little time since a 6½-h.p. Darracq to carry four, but found the car not suitable for this hilly country, viz., North Devon. Doubtless among your vast number of readers some could advise what make of car is suitable, the hills in some instances being one in seven. I require to take four occasionally, and want to provide for such. I want a simple car that can be easily learnt by a person of ordinary intelligence, smallest cost, that is reliable, speed not to exceed twenty to twenty-five miles per hour, and, as roads are not extra grand, would solid tyres be preferable?—Yours truly,

WOULD-BE MOTORIST.

TORPOINT FERRY AND MOTOR-CARS.

TO THE EDITOR OF *The Motor-Car Journal.*

SIR,—I have lately had occasion to take my motor-car across by the Torpoint steam ferry. My car is a small two-seated one, the total weight being 7 cwt., and the wheel base about six feet. For this I am charged half-a-crown. Out of curiosity, the other Saturday, when crossing, I asked the driver of a large covered wagon drawn by two horses, which was also crossing, what they charged him, and what weight he had. The driver told me he had two tons in his wagon, and was charged half-a-crown. I do not know on what basis the ferry company make their charges, but it seems to me most absurd that one vehicle which occupies about a quarter of the space of another - and weighs only 7 cwt. against nearly three tons should be charged the same. I can only conclude that the ferry company are under the usual absurd impression that a man who owns a motor-car must be rolling in wealth, and therefore well able to pay any charge, but perhaps it might

Digitized by Google

be well for them to remember there are other means of crossing the border into Cornwall besides the Torpoint steam ferry.—Yours truly,

LIGHT CAR.

PETROL IN READING.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—On Sunday, the 1st inst., I endeavoured to obtain petrol in Reading, and was finally told that I could get it at the shop kept by Collins opposite the Barracks, "agent for petrol in Reading." Mr. Collins will not supply petrol on Sundays "under any circumstances whatever." Motorists please note. In consequence of my inability to purchase petrol in Reading I was compelled to buy some at a small roadside "pub." The can was marked B, and was not sealed, and the petrol gave me an infinite amount of trouble. Here let me express my sincere thanks to the owner of a large Mercedes who kindly stopped to try and help me when my engine was at rest between Chippenham and Colne, on Tuesday, all for the want of a drop of Carless.—Yours truly,

A 391.

QUERIES *re* PANHARD CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reply to "7-h.p. Panhard," may I be allowed to state that I experienced the same kind of thing with a Panhard car, and on looking for the cause of the trouble I found the bolts of the crank-chamber right on the last threads. On tightening up these bolts I experienced no further discomfort. Hoping this will prove useful to "7-h.p."—Yours truly,

PANHARD.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—In reference to "7-h.p. Panhard's" letter in the last issue of the *Journal*, if one cylinder were misfiring, it would cause a knocking which would sound in the gear box, but if this is not the cause I should advise returning the car to the makers for remedy, as, the car being new, this ought not to be.

The best position for the gas control can only be found by experience with the car, as almost every automobile has its own peculiarities, and even two cars of the same power and size, by the same maker, will not, as a rule, run with the levers in identical positions.—Yours truly,

H. J. T.

MOTORING PROGRESS IN SOUTH AFRICA.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I enclose a cutting from "Erocott's Penny Mail," published in Grahamstown, to show you that our city fathers are not as bad as most of your English ones. You will see that they have actually put on a speed limit to horse traffic, and have excepted motor-cars.

Here in Grahamstown we are getting on slowly with the motor movement. Three Oldsmobiles, two Stars and one Clement. In a week or two we expect a couple more little Stars, and I am, I hope, getting out my third Star, a four-cylinder one. Our roads are fearful, surface bad and gradients stiff, and yet, in spite of all, the motor-car is the correct means of getting about. I have done my entire practice for twelve months now on my two cars, a small two-seated 7-h.p. and a four-seated 10-h.p., and, as my medical work has often taken me out thirty-five miles, it is no inconsiderable saving in time, and I find it cheaper than horses. "Good luck to the motors," say I.—Yours truly,

G. G.

WHEEL v. TILLER STEERING.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—A couple of years ago wheel steering had made such advances in public favour that predictions were freely advanced that it would within a very short time become universal. That prediction has not been fulfilled, of course. Lever and tiller steering are still with us, and to all appearance there is not the slightest probability of its falling into disuse. At the same time wheel steering has made decided progress. No maker has turned from wheel to lever steering, while many have forsaken the lever and tiller for the wheel. Popular favour is possessed by or assumed for the wheel, but it will scarcely be denied that just as the wheel is the natural method of steering to be used on some cars, so the lever or tiller is the equally logical accompaniment of others. The choice should be made, not in obedience to the dictates of fashion, but in consequence of known peculiarities of cars and the adaptability of wheel or lever steering to them. The big car, equally with the speed car, demands the steadiness and reliability that come with the adoption of the wheel. But the superior claims of the lever, with its quickness and ease of manipulation, are quite as indisputable. It would be interesting to have the opinions of those motorists who have given both systems of steering devices a practical trial.—Yours truly,

TILLERLEVE.

A Breakdown in Early Motoring Days.

BOYER CARS.—Replying to Mr. P. White, full particulars of these cars can be obtained from Messrs. Boyer and Company, 64, Avenue de la Grande Armée, Paris.

CARBURETTOR TROUBLES.—Major E. H. Smith, of Arundel House, Wednesbury, writes:—"*Re* the letter on page 200 of the *Journal* for the 30th ult., I have just accomplished the very thing with my Longuemare carburettor 'Mack Siccar' requires, and if he will put himself in communication with me, I will willingly assist him in both his queries."

ACCUMULATOR CHARGING SET.—Replying to Mr. J. Darby, jun., the address of Messrs. Everett, Edgcumbe and Company is 151 and 152, Great Saffron Hill, London, E.C.

TERMINAL CONNECTIONS.—In connection with our reply to Mr. C. H. Peake last week, Messrs. G. T. Ritchie and Company, of Gray's Inn Road, W.C., ask us to mention that they have the Herz terminals in stock.

THE INDICATOR DIAGRAM OF A HIGH-SPEED PETROL MOTOR.*

By Prof. H. D. Callendar, M.A., F.R.S.

The object of this paper is to describe the method adopted for obtaining high-speed indicator diagrams, and to show how the indicator may be utilised in the study of the theory of the motor, and as a guide to its practical improvement. The motor employed in the experiments is a Clement-Garrard, with 60 mm. bore and 70 mm. stroke. The cylinder capacity is 198 c.c., and the clearance volume approximately 60 c.c. The valves are on the top of the cylinder, and a fan is arranged on the flywheel to deliver a blast on the exhaust valve side, which is necessary to prevent the valve being injured when the engine is run continuously for a long time on the stand. The inlet valve is automatic, and is provided with an arrangement for varying the tension of the spring for experimental purposes while the engine is running.

The indicator used is a Hospitalier-Carpentier manograph, with certain modifications necessary for high-speed work. It is connected directly to the cylinder by a short steel tube, 5 mm. bore, in place of the long fine copper tube usually employed. The pressure acts on a thin steel disc, the movements of which are communicated to a large pivoted mirror, which is tilted upwards through an angle proportional to the pressure acting on the disc. The movement of the mirror is observed or recorded by a ray of light reflected on to a screen or photographic plate. In order to record the pressure at each point of the stroke in the form of a continuous curve or diagram, the mirror is simultaneously tilted from side to side by a little crank revolving in time with the fly-wheel, so that the spot of light reflected from the mirror moves horizontally in time with the motion of the piston in the cylinder. Owing to the high speed the spot of light is seen as a continuous curve, which is readily measured or photographed.

Simple diagram.—The relation of the indicator diagram to the cycle of operations taking place in the cylinder of the motor will be readily understood by reference to a simple diagram. The straight horizontal line, A T, which the spot of light describes when the pressure is atmospheric on both sides of the steel disc of the indicator, is called the atmospheric line. When the piston is at the top of the exhaust stroke, the spot of light is at A, and the pressure in the cylinder is practically atmospheric. As the piston moves outwards on the suction stroke, the spot of light describes the line A B. This falls considerably below the atmospheric line at high speeds, showing a negative or suction pressure (required to draw the charge into the cylinder) of more than half an atmosphere. At B the piston turns and begins to compress the charge. As the charge is compressed, the pressure rises, as shown by the curve B C, reaching a maximum (in this case of 47 lb. per square inch) at C, when the piston has again reached the top of its stroke. Shortly before this, at the point S, the spark occurs in the cylinder and fires the charge. The spark itself can be photographed on the plate by using a spark gap in the focus of the mirror. Although the explosion pressure takes less than a hundredth of a second to develop, even with a very weak mixture, as in this diagram, the piston has already reached the middle of its outward stroke, at the high speed of 2,400 revolutions per minute, before the combustion is complete. The pressure is never quite the same in successive explosions at this speed, so that the explosion lines do not exactly coincide. The exposure of the photograph in this case lasted three-quarters of a second, and includes fifteen successive explosions. At the point D on the diagram, the exhaust valve opens near the end of the stroke, and the pressure in the cylinder rapidly falls to the atmospheric, before the piston has had time to turn. During the exhaust stroke, from T back to A, the piston is pushing the remainder of the exhaust gases out of the cylinder, and the pressure in consequence rises a little above the atmospheric line at E.

Revs. 2430. Light.

The work done by the motor depends on the average excess of pressure in the explosion stroke C D over that in the compression stroke C B. This is called the mean effective pressure, and when multiplied by the area of the piston and by the length of stroke (*i.e.*, by the cylinder capacity) gives the gross work done per explosion. This is reduced to foot-pounds, multiplied by the number of explosions per minute, and divided by 33,000 to get the gross indicated horse power. The work done by the piston against back-pressure and suction during the pumping strokes, T E A and A B, may be also ascertained from the diagram, and deducted so as to obtain the net indicated power; but it is in some respects more convenient to include these necessary losses with mechanical losses such as piston and bearing friction.

The diagram illustrated herewith was taken with the engine running light on the stand, the gas supply being throttled by reducing the lift of the inlet valve, so that the explosion pressure was comparatively weak. As the throttle is opened, and the engine is made to do work on the brake, the explosion pressure is much greater, the pressure rises steeply at C, and the area of the diagram, which is proportional to the work done per explosion, is greatly increased. On the other hand, if the spark is retarded so as not to take place till after the piston has turned the corner at C, the pressure does not begin to rise till late in the stroke, and the engine runs comparatively slowly.

The nominal brake horse power of a motor is generally estimated from the cylinder capacity and speed, or measured by a brake acting on the flywheel. Given a complete motor-cycle, with the engine already fitted in position, it is more convenient and satisfactory to measure the brake horse power by applying a brake to the tyre of the road wheel. This is easily done if the brake is cooled by water circulation, and the tyre lubricated with glycerine. The brake horse-power so determined includes transmission losses in the belt or chains and bearings, and gives the power actually available for propelling the machine.

The principal defect of the air-cooled motor is that, if it is run at full power continuously, the cylinder rapidly becomes too hot for efficient lubrication, the motor loses power from excessive friction, and refuses to go when power is most wanted, as in hill-climbing on a low gear. To run such a motor at full power it is necessary to employ artificial methods of cooling. For moderate sizes air-cooling by a fan is preferable to water cooling, as it is much lighter and less likely to cause trouble. Another reason of the falling off in power when the cylinder is very hot is that the incoming charge is heated and expands, so that less mixture is drawn into the cylinder. The compression pressure is also higher, owing to the gas receiving heat from the hot walls of the cylinder during the compression stroke.

The commonest of all defects is imperfect or variable ignition from a weak spark or a dirty plug. This is shown, especially at high speeds, by sluggish rise of pressure and great irregularity in successive explosions, even if the spark is not so bad as to cause misfires. Leakage is a fruitful source of loss of power, but is easily detected by testing the compression. A leak shows itself on the indicator diagram as a loop at the end of the compression stroke if the spark is retarded, coupled with a rapid fall of pressure during expansion. The commonest leaks occur at the sparking plug or the exhaust valve. A leaky plug gets overheated by the hot gases, and soon misfires or cracks. A leaky exhaust valve gets badly burnt.

Back-pressure, due to insufficient exhaust lift or to a throttled silencer, does not produce very serious loss of power directly unless the throttling is excessive. Indirectly its results are more serious by overheating the engine. The gain of power due to omitting the silencer is generally due mainly to the fact that the rapid escape of the exhaust keeps the engine much cooler.

Errors of timing the valves rarely occur unless the engine has been taken to pieces and re-assembled with insufficient knowledge. When running slow, the exhaust valve should close slightly before the end of the stroke. The diagram shows that there is, as would be expected, a slight lag in closing at high speeds. It is difficult to get the engine to run at all if the timing is wrong by so much as a tenth of a revolution.

The proper adjustment of the strength of the valve springs is a matter which generally receives careful attention at the hands of the makers. Troubles are often occasioned by the springs becoming weakened by overheating or otherwise. If the exhaust spring is too weak to keep the valve closed against the suction, burnt gases are drawn back, and the charge is weakened. This is especially liable to occur with a stiff inlet spring, and makes the engine weak at high speeds. The defect is readily detected by the indicator by holding up the inlet valve so that it cannot open, and driving the engine by pedalling or otherwise. The exhaust spring should be strong enough to hold the valve closed against the atmospheric pressure. A useful auxiliary method of governing or regulating the speed is to employ a spring exhaust lifter, the effect of which is not actually to open the exhaust valve, but to diminish the effective strength of the spring. This does not heat the cylinder like throttling the exhaust, but weakens the mixture by suction leakage.

With an automatic inlet valve the strength of the spring is a most important consideration. If the spring is very weak, the suction pressure is diminished, and a larger charge is drawn into the cylinder, giving more power at low speeds, which is useful for hill climbing. But at high speeds a weak spring does not close sufficiently quickly and steadily to retain the charge, and the diagrams show unsteadiness and loss of compression. A stiff spring is suitable for high speeds, but it throttles the gas too much for hill climbing. The only satisfactory solution is to fit an arrangement for varying the tension of the spring, which may easily be designed to serve also in place of a throttle valve.

Speaking generally, the diagrams indicate that loss of power at high speed is due rather to diminished charge than to back pressure. A good deal of the suction loss is due to the carburettor, and could not be cured by fitting a mechanical inlet valve. Some suction loss is probably necessary to secure a good mixture at high speeds, as the time of mixing is so short; but any devices for getting more mixture into the

* Abstract of Paper read before the Auto-Cycle Club, at the Royal College of Science, South Kensington, on Wednesday, May 4th.

Digitized by Google

cylinder would evidently be futile, unless at the same time effective provision were made for cooling the cylinder. In any case, the thermal or fuel efficiency would be lowered owing to the higher explosion temperature.

HEAVY MOTOR-CAR REGULATIONS.

THE President of the Local Government Board laid upon the table of the House of Commons on Friday last week the report of the Departmental Committee on motor-cars. The committee, which consisted of Mr. Henry Hobhouse, M.P. (chairman), Sir William Arrol, M.P., Mr. H. C. Monro, C.B., Mr. H. H. Law, Mr. G. F. Deacon, C.E., and Mr. H. Graham Harris, was requested "to enquire and report with regard to any regulations which should be made under Section 6 of the Locomotives on Highways Act, 1896, and Section 12 of the Motor Car Act, 1903, as respects any class of vehicle, for the purpose of increasing the maximum weights of three and four tons mentioned in Section 1 of the former Act, and with regard to any conditions as to the use and construction of the vehicles which should be made by any such regulations. The committee held thirteen meetings and examined twenty-eight witnesses, including representatives of county councils and municipal corporations, the Automobile Club, officials of railway and omnibus companies, motor manufacturers and traders, and the Roads Improvement Association.

The following is the text of the Committee's recommendations:—

(1) That the maximum weight of three tons and four tons for unladen motor-cars mentioned in section 1 of the Locomotives on Highways Act, 1896, shall be increased to five tons and six and a half tons respectively.

(2) That the total gross weight on any one axle of a motor-car when laden shall not exceed eight tons.

(3) That every motor-car which exceeds two tons in weight unladen shall be marked conspicuously on its right or off side with (*a*) the weight of the car unladen, and (*b*) the gross weight to be carried on each axle when laden.

(4) That these weights shall be certified, when the motor-car is registered, by an officer of the registering authority who has seen the vehicle weighed when unladen, and each axle of the vehicle weighed, when laden, that the motor-car shall not be registered without this certificate, and that the weight so certified shall be entered in the register for motor-cars.

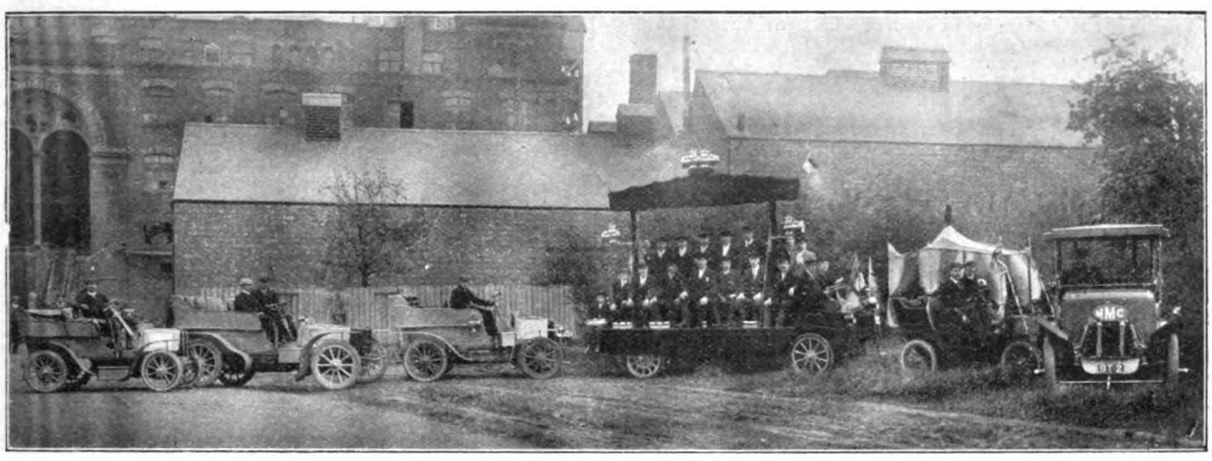
(5) That any motor-car registered as being over the unladen weight of two tons before the issue of new regulations shall be liable to be weighed and re-registered, but without any further charge by the registering authority.

(6) That every "trailer" (*i.e.*, a vehicle intended to be drawn by a motor-car) shall be conspicuously marked on its right or off-side with its weight unladen, and, if such weight exceeds one ton, with the gross weight to be carried on each axle when laden. The gross weight to be carried on any one axle of the trailer shall not exceed four tons.

(7) (*a*) That in the case of metal tires the width of the tyre of every wheel of a motor-car exceeding two tons in weight unladen shall be regulated as follows:—If the wheel is three feet in diameter the width of the tyre shall be not less than half an inch for every seven and a half cwt., or fraction of seven and a half cwt., of the certified gross weight to be carried on the axle to which the wheel is attached. If the wheel exceeds three feet in diameter the foregoing rule shall apply with a proportionate increase above the seven and a half cwt. in the ratio of one cwt. for every twelve inches increase in the diameter of the wheel. If the wheel is less than three feet in diameter the foregoing rule shall apply with a proportionate decrease below the seven and a half cwt. in the ratio of two cwt. for every twelve inches decrease in the diameter of the wheel. Provided always that the width of tyre shall in no case be less than five inches. (*b*) That in the case of a motor-car exceeding two tons in weight unladen, and in the case of a trailer exceeding one ton in weight unladen, the diameter of any wheel having a metal tyre shall not be less than two feet. (*c*) For the purpose of the above measurements the diameter shall be the extreme diameter of the wheel measured from the outside of any tyre or other portion of the wheel which will come into contact with the ground.

(8) That the width of the tyres of a trailer exceeding one ton in weight unladen and having metal tyres shall be regarded in the same way as the tyres of a motor-car, gross weights marked on the vehicle being substituted for certified gross weights.

(9) That metal tyres shall be smooth and flat, provided that the tyres may be either solid or constructed with diagonal cross plates having parallel spaces between the plates so arranged that any straight line drawn across the width of the tyre parallel with the axle shall be in contact with metal for at least seven-eighths of the total width of the tyre. The above requirements shall not prevent the bevelling of the edge of the tyre for not more than one-tenth of its width on either side. [We consider that there would be an advantage in having the edge of the tyre slightly curved, so as to avoid a cutting edge on the road surface.]



(10) That the maximum speed of a motor-car shall be regulated as follows:—(*a*) In the case of a motor-car having its wheels fitted with metal tyres the speed shall not exceed—(*i*) eight miles an hour when the certified gross weight on any axle exceeds three tons, and does not exceed six tons; (*ii*) five miles an hour when the certified gross weight on any axle exceeds six tons, or when the weight of the vehicle unladen is three tons, or over three tons and a trailer is used. (*b*) In the case of a motor-car having its wheels fitted with non-metallic resilient tyres the speed shall not exceed twelve miles an hour when the certified gross weight on any axle exceeds three tons and does not exceed six tons.

(11) That the width of a motor-car of, or exceeding, three tons in weight unladen, or of a trailer drawn by such car, shall not exceed seven feet six inches between its extreme projecting points.

(12) That the officer of any highway authority shall have power to require the driver of a motor-car exceeding two tons in weight unladen, which may be within a quarter of a mile of a weighing machine, to proceed thither for the purpose of weighing the motor-car or trailer with the load it is carrying in such a manner as to ascertain the weight upon each axle. If the weight on any axle thus ascertained exceeds the weight marked on the vehicle in respect of that axle, the driver or person responsible for the load shall be deemed to have committed an offence against the regulations.

(13) That no motor omnibus or other passenger motor vehicle of or exceeding three tons in weight unladen shall be used to draw a trailer.

(14) That every motor-car of, or exceeding, three tons in weight unladen, and every trailer shall be constructed with springs on each axle.

The Fleet of M.M.C. Cars which took part in the Lifeboat procession at Coventry on Saturday last.

CLUBS AND ASSOCIATIONS.

SHEFFIELD AND DISTRICT.

THE annual hill-climbing competition for the challenge cups presented by Mr. Harvey Foster (at present held by Messrs. H. Cooper and W. H. Brown) will again take place on Padley Wood Hill, that for motor-cycles on June 4th, commencing at 2.30 p.m.; and for cars on June 18th, commencing at 2.30 p.m. Entries for the cycle competition must be sent in on or before the 21st inst., and for the car trial before the 28th inst. The start will be on Padley Wood Hill, near the Maynard Arms Hotel, and the finish near Fox House Inn, and all vehicles will be allowed a flying start. Cars and cycles must be driven by the owners, and be their *bona fide* property at the time of entering their names. An Observer will accompany each car, and each cycle will be followed by an

Digitized by Google

Observer on another vehic'e. Passengers may be carried, but they must not dismount during the competition, and the car with its load will be weighed the same day. Cycles and their riders will also be weighed.

SCOTTISH.

TROON was the rendezvous of the western section of the Scottish Automobile Club on Saturday last, and the informal meet consisted of about two dozen cars. The day was fine and the famous links in front of the hotel were crowded with golfers. It was the day of the Spring Meeting, and a number of motorists who are members of the Golf Club took the opportunity of a round of the green. The presence in the hotel of many well-known ladies engaged in the championship meetings at present being held on the Ayrshire Golf courses lent an added interest to the afternoon.

SOUTH AFRICA.

THE second annual dinner of the Automobile Club of South Africa was held in Cape Town on the 11th ult., when Mr. A. T. Hennessy, the president, occupied the chair. After the usual loyal toasts were honoured, Colonel Crewe, replying to the toast of "Our Guests," given by Mr. D. P. de Villier Graaf, the Vice-chairman of the Club, related some amusing anecdotes in connection with the election campaign which had recently taken place. Sir L. Mitchell followed with "The A.C. of South Africa," which he proposed in very humorous terms, and specially congratulated the A.C.G.B.I. for the good work which they had done in the interests of automobilism. The President, in responding, was very emphatic in regard to due consideration being given in Africa by automobilists to other users of the road, and mentioned that the club had asked the local authorities to particularly deal with any automobilists transgressing the usual rules of courtesy on the road. The club were establishing a system of hotel accommodation under special arrangements throughout the country. The final toast, prior to the usual vote of thanks to the chairman, was "The A.C.G.B.I.," to which Mr. Rudyard Kipling responded. Opening with some characteristic humorous remarks on the previous speeches, he in similar strain said that he wished to protest against the statement of some of the gentlemen that motoring was in its infancy. He knew the child. He did not say that he was present at its birth, but he helped to nurse the rickety thing along. The men that deserved a statue, the men that deserved the consideration, the love and affection, and reverence of their fellow men, were the men—"maniacs" they used to call them—who years ago laid their right shoulders to the wheel and pushed the whole thing along.

MIDLAND.

THE members of the Midland Automobile Club have been invited by their president, Mr. J. Broughton Dugdale, to visit his residence at Wroxall Abbey to-day. An open hill-climbing competition will take place at Sun Rising Hill on July 23rd, on the main road between Stratford and Banbury, under the same conditions as last year. An inter-club hill-climb is down on the fixture list for September.

A POINT FOR DEALERS.

AT the South Western Police Court, a few days ago, Wm. May, of Clapham, appeared to an adjourned summons for fraudulently allowing to be used by Ernest Sullivan a mark for identifying a motor-tricycle. His brother John was summoned for that, as a dealer, he failed to keep a record of the distinguishing number annexed to the identification plates of the tricycle; and Ernest Sullivan was summoned for driving a motor-tricycle which was not registered. It appeared that a dealer's plate was wrongly used, the defendant not knowing that it could not be used for hiring purposes. He had a record, but not for private use of motors, which was the case on this occasion. Mr. Fenwick fined each 20s., or 14 days' hard labour.

CASES DISMISSED.

SHERIFF FYFE disposed of an interesting case last week in the Glasgow Small Debt Court, when James Parker, Callander, sued John Hunter, Downanhill, Glasgow, for £10 in respect of the loss of a bull terrier dog, which was run over and killed by defender's motor-car. In giving judgment for defender, the Sheriff said that the speed of ten miles an hour at which the car was going was not excessive, and that the driver was justified in holding on his course, seeing that the dog was presumably nimble and able to take care of itself.

A CASE of considerable importance to motorists has just been decided in the Paisley Sheriff Court by Sheriff-Substitute Lyell. The action was brought by Mr. John Melville, the proprietor of a brickworks at Brora, Sutherlandshire, against the Mo-Car Syndicate, Limited, Paisley. The pursuer sought damages in respect of a collision which took place between one of his horses and one of the Arrol-Johnston cars. The facts of the case, briefly, were that a 12-h.p. Arrol-Johnston car was being driven northwards on the left hand side of the road between Golspie and Helmsdale by one of the defenders' drivers, when the foremost of two horses which were drawing a bogie belonging to the pursuer commenced to cross the road immediately in front of the car from left to right. The result was that the horse and car came in contact, but only after the latter had been almost pulled up. The main road at this point is crossed by a tramway line leading from the pursuer's works to the railway station, and it was along this line that the horses and bogies were proceeding. The pursuer's case was, (1) that the car was being driven at an excessive speed, over thirty miles an hour; (2) that the driver was not keeping a proper lookout; and (3), that he failed to draw up though he had ample time to do so. In support of his averment as to the speed of the car, the pursuer adduced the evidence of several witnesses. One of these stated that the car was going at thirty-five miles an hour, but at the same time he said, in cross-examination, that the car took a minute to travel a distance of a hundred yards, which, of course, is equal to about 3½ miles an hour! Another witness made the even more extraordinary statement that in the time the horse walked from the centre of the road to the side the car travelled from a point fifty yards distant and collided with the horse! As the horse would traverse the distance in 3·88 of a minute the car would require to have travelled the fifty yards at fifty miles an hour. This result, however flattering it may be to the makers of the car, is of course a *reductio ad absurdum*. The defenders' side of the question was that they were travelling at about twelve miles an hour; that they were keeping a proper lookout, but were unable to see the horse until it appeared on the road owing to the foliage on the roadside; and that the pursuer's driver was not at the horse's head. They further stated, and substantiated the fact by the evidence of the occupants of the car, that the horse appeared when they were about six yards from the opening and that the driver brought the car almost to a standstill within that distance. It was also proved that the car could not possibly have been going at more than fourteen miles an hour. It was successfully argued for the defenders that the wild statements of the pursuer's witnesses as to the speed of the car could not be relied on, and that as the pursuer was using the road for a private purpose and not in the ordinary way, his servants should not have crossed it without first ascertaining whether or not any vehicle was approaching, the roads existing primarily for the benefit of those travelling along them, whether on foot, or horseback, or in vehicles.

His Lordship has assoilzied the defenders with expenses, and it is to be hoped that his decision will have a deterrent effect upon the indiscriminate raising of actions of damages. The pursuer, who had twenty-eight days in which to appeal, has now acquiesced in the judgment.

JOSEPH BARBERRI was summoned before the Southampton Borough Bench for having driven a motor-car at a speed which was dangerous to the public, in Above Bar Street, on April 29th. P.C. Lucy gave evidence to the effect that the defendant was proceeding at a fast pace. When approaching witness, defendant slowed down; after passing him he put on speed and went at a pace which witness estimated at sixteen miles an hour. The defence was that a mistake had been made, and that the car spoken of was not the car driven by the defendant. Mr. Lamport said he was instructed by the defendant's employer, Sir William Pearce, Bart., who gave the defendant the character of being a most reliable driver. Defendant went into the witness-box and declared that he never drove furiously on this occasion. The magistrates gave defendant the benefit of the doubt on the question of identity and dismissed the summons.

Motor-Car Journal

VOL. VI.] LONDON, SATURDAY, MAY 21, 1904. [No. 272

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

ONE result of the motor-car week in Manxland should be to give a fillip to the industry. The surface of the roads is extremely good, and although the many sharp corners may test drivers just as the steep hills will try cars, there are opportunities for motoring that should be taken advantage of by the local gentry. We heard of several medical and legal gentlemen who took their first automobile trip last week, and doubtless Mr. J. R. Corlett, of Douglas, has already persuaded some of the residents into becoming motorists. During the week he accommodated no less than twenty-four motor-bicycles in his establishment on the Promenade, and also found similar provision for several cars that were taken to the island by English motorists.

◆ ◆ ◆

The Lincolnshire Clubs.

A CONFERENCE between delegates from the Lincolnshire Automobile Club and the South Lincolnshire Motor Club was held at the Red Lion, Boston, on Thursday of last week to discuss the future relations of the two organisations to each other. Despite reports to the contrary, the South Lincolnshire Motor Club determined to maintain their independence, and, we understand, declined to form any amalgamation with the Lincolnshire Automobile Club. It was, however, unanimously resolved that where the cause of automobilism and where cases of motor politics were concerned the two clubs should act together by means of a joint committee formed of an equal number of members from both clubs. It is sincerely to be hoped that the relations between the two clubs will now become more cordial, and that, grievances having been well discussed, both parties will "bury the hatchet" and work for the common cause. With the enormous increase of motor traffic in Lincolnshire (the second largest county in England) there is surely room for two clubs, especially if they are prepared to work in harmony when occasion requires.

◆ ◆ ◆

Motor-Boat Trial.

FROM the technical secretary of the A.C.G.B.I. come the rules for the reliability trial for motor-boats fitted with internal combustion engines, which is arranged to be held in Southampton water on July 26th and 27th of the present year. The object of the trial is to prove that boats propelled by internal combustion engines can be depended upon for continuous and reliable runs, and the regulations provide that the boats must be fitted with effective silencers and carry sufficient fuel to last for the whole of the twenty hours' run. The route will consist of an approximately rectangular course, each competitor being required to run round for a period of ten hours each day. There will be five classes, and unless ten entries are received by the 11th prox. the committee reserve to themselves the right to abandon the trials. The winner in each class will be the boat with the highest number of marks, this being arrived at by its possession of the qualities of reliability, speed, safety, and economy, as well as its general condition after the trial. Mr. Basil Joy will be pleased to forward to any intending competitor a copy of the complete rules.

London Traffic.

MANY and varied were the suggestions made at the meeting of the Surveyors Institution during the adjourned discussion on Mr. Thomas Blashill's paper on "London Streets and London Traffic." The general opinion was that the laying out of new main thoroughfares was so costly that it would be unlikely to be undertaken; indeed, the figures relating to such schemes were so staggering that one speaker expressed surprise that the advocates of them had not at once suggested moving London bodily twenty or thirty miles away and beginning afresh. What was wanted was more direct routes, which could be obtained by widening existing streets at comparatively small cost. Tram lines in crowded thoroughfares were condemned and the alternative suggested was the more flexible motor traffic on roads with a smooth, easily repairable, thin surface on a permanent foundation or bed. Mr. Blashill's opinion was that slow traffic would, save in very exceptional cases, be quite done away with; it would be better, cheaper, and easier to take the heaviest loads at a quick pace, and then all the traffic would proceed together. An important point in the removal of obstacles was the organisation of work done to the surface of the road, and Mr. Howard Martin suggested a central licensing authority; there would be no improvement if it were left in the hands of the borough councils, who, in the matter of breaking up the roads, were the worst offenders.

◆ ◆ ◆

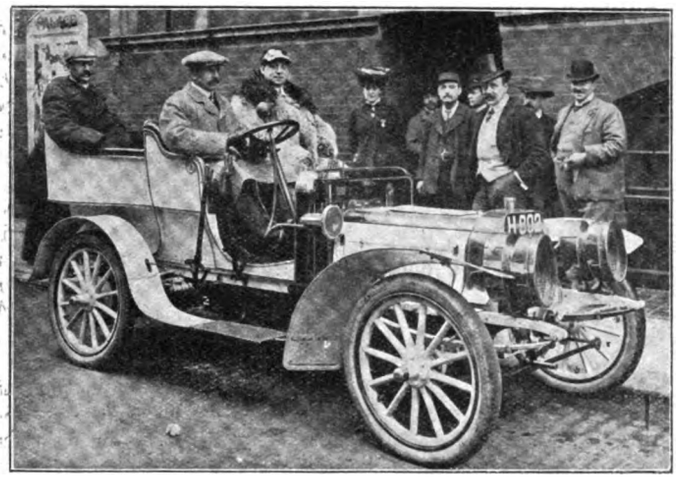
Club Repairers.

MANY of the provincial clubs are becoming of real utility to their members, and some of the smaller organisations particularly have shown great enterprise in their early development. The East Surrey Club, which has its headquarters at the White Hart Hotel, Reigate, has just appointed an official repairer, whose charges will be subject to the arbitration of the club, and who will be expected to give members the first call on his services. His appointment is to be held for one year, and is subject to the approval of the annual general meeting. Driving will also be taught to members, who will have the opportunity of storing cars at his place. This is an important development for a local club to undertake, and will doubtless suggest a practical notion to some other provincial associations of motorists.

◆ ◆ ◆

Cars and Consumption.

ACCORDING to Dr. Blanchet, of Lyons, motoring is an absolute cure for consumption. He says that to cover 100 miles a day in an open automobile would be an effective remedy for the tuberculous cough of consumptive patients, for it produces at the same time that healthy sleep and appetite conducive to their good state of health. In an article in the "British Medical Journal" he says that after an attack of influenza in 1898 he suffered from pleurisy and gradually declined in health, until two years later he had to give up work practically altogether. By the open air treatment he was partially restored. He did not quite regain his usual health until he had bought a motor-car, in which he drove twice a day about fifty miles. The result was that he lost his cough, recovered his appetite, and steadily regained his health. This experience is identical with that of the late Sir Henry Thompson, and we



Digitized by Google

would suggest that, in connection with open air sanatoria and other institutions now being introduced in this country, the provision of a motor-car should be made to assist the effectual remedy of consumptive patients.

◆ ◆ ◆

Professionals and the Car.

THE motor-car is now being pressed into service for the rapid conveyance of theatrical parties from one town to another. The accompanying illustration shows Mr. Montague Atkinson leaving the Palace Theatre, London, W., on Wednesday morning last week, with Mr. Arthur Roberts and

two other artistes, on his 20-h.p. Spyker car. The start was made at 10.30 a.m., and Bexhill reached at two o'clock, in time for lunch, after which Mr. Arthur Roberts and party gave an entertainment at the Kursaal. The return journey was commenced at a quarter to five, the Palace Theatre being reached just as the clock was striking eight. Both runs were non-stop, except for half an hour's rest at East Grinstead on both the outward and return trips.

◆ ◆ ◆

The Endorsement of Licences.

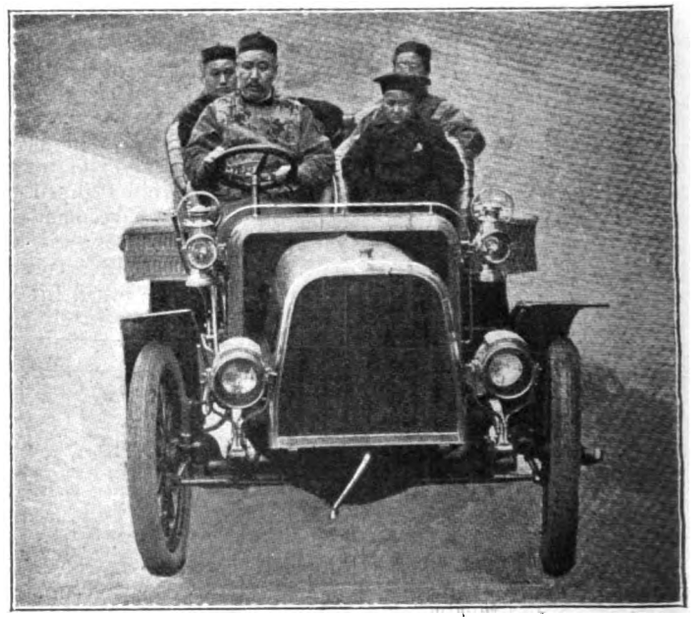
VARIOUS are the methods of police magistrates, whose want of uniformity in judgment is becoming something akin to a scandal. At West Ham, the other day, a motor-cyclist who had left his licence at home was fined, and his licence was endorsed. It was an error of carelessness that might well have been met by the fine, or, perhaps, the payment of costs. But to endorse the licence, thus branding the driver as in the same category as those who drive recklessly, is manifestly unfair. Such decisions as these tend to bring disrespect to the law, and to make motorists often feel something of the pangs of martyr souls. This question of the endorsement of licences is an important one, and we trust one of the many organisations connected with automobilism will give the matter earnest consideration, with a view to securing some revision of these magisterial judgments.

◆ ◆ ◆

Unequal Sentences.

ANOTHER aspect of the same subject is presented in the way that some magistrates deal with drivers of vicious animals. At the Clerkenwell Police-court evidence has been given as to the running away of two horses attached to a brewer's dray. They dashed along a crowded street and collided with an omnibus, knocking down one of the horses drawing the vehicle. In the course of their wild career they threw down two other omnibus horses, turned over a milk cart, injuring the horse attached thereto, and finally became wedged between a couple of tram-cars near the Euston Road. Such antics were a source of serious danger to other users of the roadway, and yet the driver was only fined £2—for being drunk. On the same day, at the Kingston Court, a motorist was fined £10, and his licence endorsed. His offence was that of driving a car at a speed of thirty-one miles an hour. No real danger was apparent to those on the roadway, and yet he was mulcted in penalties to the extent of five times as much as the fine imposed on a drunken driver who injured several horses and narrowly escaped injuring human beings.

◆ ◆ ◆



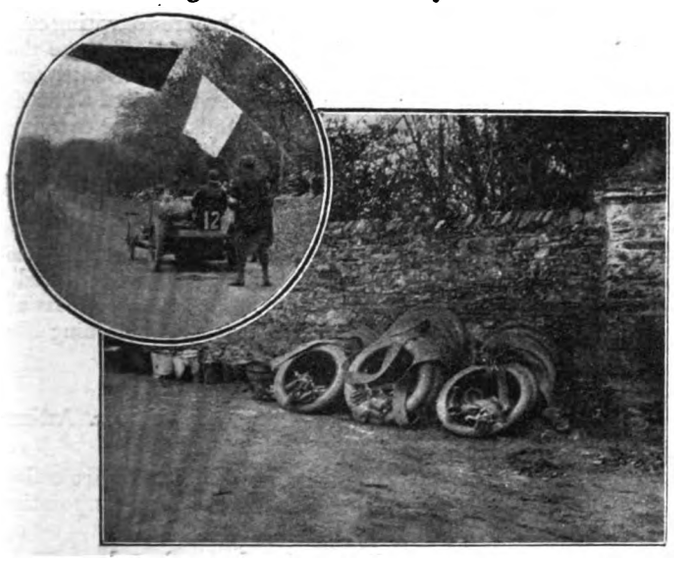
Motor-Car Services.

SEVERAL new public motor-car services are about to be inaugurated, and that between Modbury and Plymouth, due to the enterprise of the South Hams Motor Carriers, Limited, is expected to start on Whit Monday. We hear, too, of several garages which are opening for the holidays, and shall be glad if motoring readers, who have experience of these new places during the next few days, will inform us of the way in which they cater for cars and men. The publication of such information will be of service to the many drivers who may be expected to be upon the road during the coming summer, and who are entirely at the mercy of those who claim to possess not only accommodation for cars, but also the facilities for repairs, which are too often found to be wanting.

◆ ◆ ◆

Diplomatic Motoring.

THE extent to which motoring has been taken up by the various diplomats attached to the foreign legations at Washington, U.S.A., is a strong token of the universal popularity of the new means of locomotion. Practically every country in the world is represented at Washington, in the person of its duly-accredited officials, and that these many men from many lands, typifying as they do the customs and traditions of widely differing and even of variously civilised populations, should so unanimously approve the modern motor-car, constitutes a striking commentary upon the force of progress as opposed to ancient institutions. The most surprising feature of automobile use in Washington is, states the New York "Motor," the vogue it has



Chentung Liang-Cheng, the Chinese Ambassador to the United States, at the Wheel of his Car.

attained among the Orientals. That the motor-vehicle should find favour with the Ministers from France and Germany is not to be wondered at, for those countries were pioneers in the new development, and motoring was widely popular in Europe almost before it was heard of in America. But that the Ministers from Korea and Japan, and the Chinese Ambassador and his secretary, should be found literally in the van of civilisation, not only to the point of riding in, but even to the extent of driving their own motor-cars, is altogether an unprecedented renunciation of Oriental conservatism.

Motor-Cars in Richmond Park.

AT the last meeting of the Richmond Town Council the General Purposes Committee reported that they had had under consideration the question of motor-cars in Richmond Park. They were communicating with the Councils of Kingston and Barnes with a view to approaching H.M. Office of Works on the subject. Alderman Burt said he had seen a gentleman at the Office of Works, and gained some idea of the rules and regulations on this subject to be laid before

The Isle of Man Trials.—The Start at Quarter Bridge.—Spare Tyres at the Starting Point.

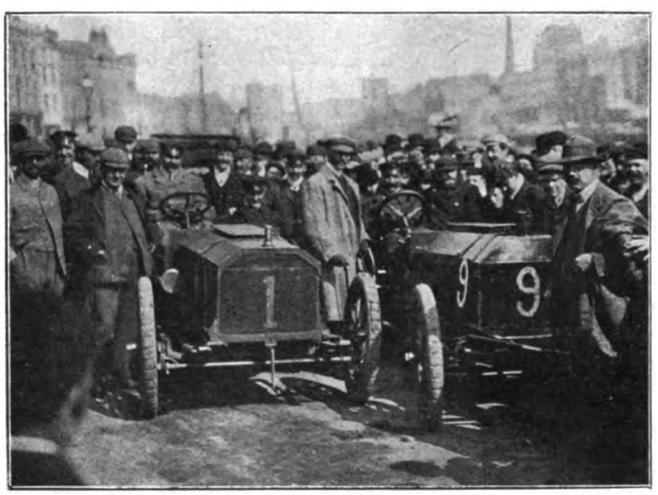
Parliament. He thought that some regulation as to the speed of motor-cars in Richmond Park would be welcome, as they were often a great nuisance and a great danger. He proposed:—"That in the opinion of the Richmond Corporation the speed limit in the Park should be ten miles an hour." This was a good speed for anything else, and the Park was a place for rest, recreation and quiet. If motorists wanted to go at a great speed they should travel outside the Park. Councillor Hilditch seconded, and complained that instead of fresh air in the Park, pedestrians were compelled to inhale burnt petroleum. Councillor Morgan thought they should cultivate a broader spirit of "live and let live." The motor-cars had come to stay, and he considered that Parliament had placed sufficient restrictions upon them, without that Council taking any steps. Councillor Chancellor and Councillor Carless agreed that the Council should do what they could to curb the extravagant conduct of motor-car drivers. Councillor Ward said the dust inside the Park was very distressing to invalids and all who desired rest and quiet. Councillor Gibb contended that the limit of speed would not affect the points which had been raised by various speakers. The motion was carried with only one dissentient.

◆ ◆ ◆

Motoring by Moonlight.

BOMBAY motorists have found a pleasant sensation in climbing the Ghauts on their cars by moonlight. This makes material calls on the nerve and resource of the drivers, and is a task not to be too lightly undertaken. Recently two cars made the ascent in company, one being driven by the secretary of the Gaekwar of Baroda, the other by Mr. Turner Laing. The two cars started practically simultaneously from Bombay and Bandora at 11.30 p.m., and arrived within a few minutes of each other at the rendezvous at Coorla crossing at midnight. After a run at a very exhilarating pace, the foot of the Ghauts was reached about 4 a.m. The roads between Bombay and Panwell and Khandalla and Poona are such as should tempt the most diffident of motorists, while the remainder are not so bad as to deter even a mild enthusiast.

An Indian Mountain Climb.



EXCEPT that the little De Dion cars had occasionally to be relieved of some of their passengers to enable them to get over specially steep bits of the road, the rest of the climb was achieved without incident other than a halt at the reversing station. At Khandalla the good folk on their way to early morning service appeared somewhat scandalised at the fleeting vision of seven begrimed and bemasked individuals "pip-pipping" through the country on the Sabbath morn and covering their Sunday clothes with dust; but, with propects of a bath, breakfast, and a sleep only forty miles ahead, these seven individuals were unperturbed. A cloud of locusts caused some annoyance, but at 8.15 a.m. the car which had practically been leading from the start rolled gracefully up to the Connaught Hotel and was followed a few minutes after by the Gaekwar's car, which had had to slow up to allow an argumentative quadruped to decide whether to get out of its way or not. After a day's halt at Poona the motorists parted, the Gaekwar's car taking the road to Mahableshwar in company with an Argyll car recruited at the Connaught Hotel, Mr. Laing's car returning to Bombay. From the bottom of the Ghauts on to Bombay the trip was uneventful, and was made practically without stop except at Thana.

◆ ◆ ◆

The Future.

BEFORE the Institution of Engineers and Shipbuilders in Glasgow, Mr. A. Govan, of the Hozier Company, has been giving a paper on motor-cars, in which he said that the improvements of the future would lie along the line of acceleration of speed and reduction of weight. Prejudice against automobilists did not exist in the minds of the rising generation, and this was a good point in favour of the early popularisation of the car. One of the best hopes for the future was the fact that all users were displaying a passionate interest in automobiles. He referred to the fact that at the present time upwards of 1,000,000 workmen were engaged in France, directly and indirectly, on the production of motor-cars, and looked forward to the early development of this country along almost equally wide and prosperous lines.

◆ ◆ ◆

Motorists and Dogs.

IN giving judgment in a case at Glasgow last week where a motorist was sued in respect of the loss of a dog which was run over and killed by a motor-car, the sheriff made some interesting remarks on the subject of how to deal with dogs on the road. In the first place he pointed out that the principle

Digitized by Google

which makes the owner of a moving object liable for damage done to a fixed inanimate object does not apply where one moving object does damage to another moving object. More especially is that principle inapplicable where the injured moving object is such an animal as a dog which was permitted to gambol all over the roadway. As between drivers themselves, the obligations for avoiding accident are mutual. Each party has a well recognised duty towards the other, and each is entitled to assume intelligence on the part of the other, and to act in reliance upon the other doing his part. But there is no reciprocal duty in the case of animals. He was, of course, far from saying that it is not the duty of a driver to try to avoid running down animals; but what his duty may be is not a question of circumstances. He did not know that this duty had ever been defined, and the circumstances may so vary that no hard and fast rule can be promulgated. Probably, a rough and ready definition may be that when a driver sees in the road on the front of him some large slow-moving animal, such as a cow, he must calculate its probable movements and try to avoid it by slackening speed, or even by stopping; but that when the animal in front of him is a small and nimble one, such as a dog, whose movements cannot for a moment be relied upon, the driver was justified in holding his course, relying on the nimbleness of the dog to keep clear. In other words, he thought a person who takes a dog unled upon a public road accepts the risk of the traffic, and relies upon his dog being able to look after itself.

◆ ◆ ◆

Reckless Drivers.

THE drivers having had their say, owners of vehicles seem to be coming forward with their opinions on those they have to employ, and the letters we now publish will probably provoke others to give their views and experiences. The amateur motorists are largely at the mercy of those they employ, and it must be a galling experience to engage a man and then discover he is not only incompetent but that his presence at the wheel is a positive danger. From such men as these motorists should be protected; hence the reason why some sort of certificate has been suggested as a kind of guarantee. But, if such diplomas are to be worth the paper on which they are printed, they must be given by some recognised authority. And if they would maintain the credit of their calling drivers will have to cease taking out their employers' cars without permission. This is more generally done than is known, and, curiously enough, many of the accidents that have happened of late have been in connection with cars thus surreptitiously used.

◆ ◆ ◆

The Amenities of the Road.

REALLY cyclists must have regard to the courtesies of the road, and now that the touring season is opening seems a proper time to emphasize the point. On the Brighton road a day or two ago we were travelling on a Mercedes car. In front was a cyclist who persisted in keeping to the centre of the roadway, and, despite the blowing of the horn and the protestations of the driver, played the part of the dog in the manger with an obstinacy that was quite unaccountable. It has been often urged that moving traffic should be required to get out of the way of more rapidly moving vehicles, and, wherever possible, motorists should do what they can to influence public opinion in the direction of making such a rule obligatory.

◆ ◆ ◆

Enterprise in Ceylon.

WHILST the British postal authorities are apparently playing with the question of automobilism, those of Ceylon seem to be going thoroughly into the matter, and the Postmaster-General of that island is putting all the facilities he can in the way of those seeking to experiment. At the present time the roads of the island are being thoroughly examined, and we understand some of them are being prepared by the local authorities with a view to rendering them suitable for improved means of transit. When that has been done, the local postal authorities will consider the adoption of the automobile for mail service. In the meantime it might be well for manufacturers of vehicles suitable for the purpose, to send particulars of their special designs to the Postmaster-General at Colombo.

◆ ◆ ◆

Motor Roundabouts.

THE accelerated speed which is becoming habitual with a good many people, owing to the example of the motor-car, has affected even the roundabouts of the old country fair. Messrs. Savage Bros., of King's Lynn, who are devoting considerable attention to motor-vehicles for heavy traffic, are the leading firm who make this particular form of popular entertainment, and we hear with interest that they have adapted a pair of 2½-h.p. petrol motors to a motor-bicycle roundabout for carrying twenty-four persons. In late years the ordinary pedal bicycle running on the roundabout has been extremely popular at pleasure fairs, but it necessitates the pedalling, which was not so wholly popular with the public. Now, however, with the two motors fitted to the one roundabout, the public is saved some exertion, for which it is always thankful, although gratitude is not always shown. The experiment has been so successful that already the machine thus equipped has run something like 17,000 miles.

AT the moment of going to press we learn that Mr. Arthur Earp has left the hospital at Douglas.

THE President of the Local Government Board is deferring final decision upon the application of the Dover Corporation until he has further experience of similar applications.

THE Right Hon. Lord Alington has been elected president of the recently-formed Dorset Automobile Club. The Rev. Ernest D. Benison, of Farrs, Wimborne, is the hon. sec.

COMPLAINT has been made that tacks and nails have been scattered on the course in the Ardennes selected for the French eliminating trials. Several drivers who have gone over the course have had four or five punctures in a day.

THE Fiat cars which will represent Italy in the Cup race have been out on the road for some days, and are reported to have attained a speed of over eighty miles an hour. The cars will be driven by Signors Storero, Lancia, and Cagno.

AT a meeting of the Races Committee of the Automobile Club, under the presidency of Mr. Alfred Bird, on Wednesday, it was decided to adhere to the original selection of Messrs. Edge, Girling, and Jarrott as the British team in the Gordon Bennett race.

BLACKPOOL, Southport, and Berwick-on-Tweed are to be regarded by the Local Government Board as county boroughs. At present Numbers only are being assigned at these places. At Blackpool Mr. W. E. Moss has been assigned No. 1, with no letter.

THE Kent County Council has refused to accede to the request of the Hythe Town Conncil to apply to the Local Government Board for a regulation limiting the speed of motor-cars in the borough to ten miles an hour, the minimum allowed by the Act.

ON the House of Commons going into Committee of Supply to consider the vote for the Post Office Service, Lord Stanley said that the motor-car services employed by the Post Office had not been particularly successful with the exception of the Milnes-Daimler car running between London and Epping, which was doing most excellent work.

AT Bisley, on Tuesday, a demonstration was held under the auspices of some officers of the Army Medical Corps and several well-known firms, in which the automobile was utilised to advantage. Two Ivel motors were brought into requisi ion, one driving an ice-making machine, the other being surrounded with armour plate, which subsequently formed a target to demonstrate its effectiveness in war.

Motoring in Manxland.

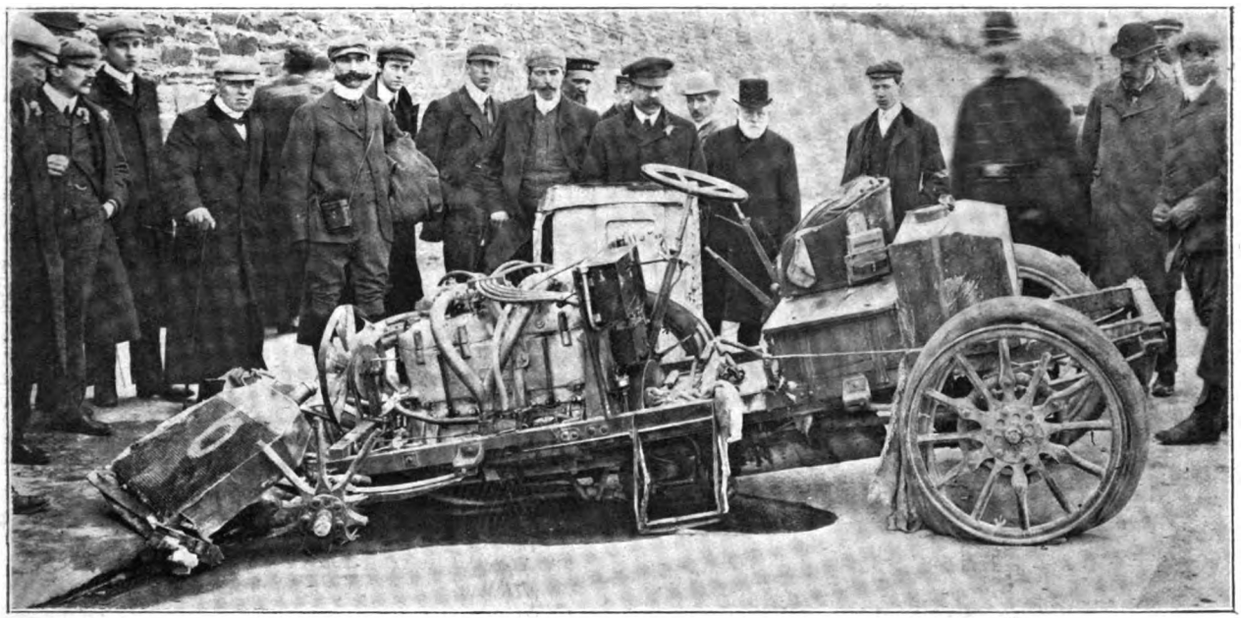

Photo by] Mr. Clifford Earp's Napier after the Accident at Douglas. *[Argent Archer.*

LAST week our account of the motoring events in the Isle of Man concluded with a report of the hill climbing competition from Port-E-Vullin to Maughold on the Wednesday. We were also able to include a report of the unfortunate mishap to a touring Wolseley, which occurred owing to the collapse of a wheel when turning one of the sharp corners with which Manxland abounds. In thus reporting fully the proceedings of the 11th inst. we were able to add the latest possible information to the greater doings of the preceding day, and outdistance our friendly rivals on the motor-press to that extent. Although the events of Thursday last have been already reported in the general press, some account must be given here, more especially as the accident at the end of the afternoon eclipsed the proceedings of the earlier part of the day.

Speed Test at Douglas.

The third factor in determining the trio to represent Great Britain in the Gordon Bennett contest was supposed to be a speed test along the Promenade at Douglas. So strenuous, however, had been the struggle on Tuesday that it was generally agreed there was no real reason for such an addition to the programme, and it was generally understood that the inclusion of a kilometre test on the Promenade was intended as a compensation to the people of the island whose roads had been closed earlier in the week. This view was strengthened when it transpired that the original time of starting was altered to meet the times advertised by the insular railway companies in connection with their cheap excursions.

Shortly after three o'clock, the Promenade had an animated appearance, thousands of people lining the sea wall, a row of seats being their main restraint. The way in which the men formed the outer rows, those nearest the track being women and children, was testimony to the kindly nature of the Manxmen as well as their instinct of curiosity. At each end of the road barriers had been erected opening inward to allow of the passage of the tramcars to the latest moment for beginning the programme. These seemed too near the start and end of the kilometre, and we subsequently learned that the one at the conclusion of the run was removed to allow the cars to stop without risk.

Major Lloyd was starter; the electrical timing apparatus was as conspicuous and useless as usual; and everything presaged success as the competitors drew up in order:—Messrs. Stocks, Hargreaves, Earp, Muir, Edge, Girling, Jarrott, and Rawlinson. They were sent off, one at a time, for a preliminary spin over the kilometre, which had an awkward turn at the further end and was marked along the centre with tramlines that made the track anything but a suitable one. All the competitors having had a preliminary canter, they returned in Indian file for the first try, which resulted in two of the Napiers making the first and second best times. Then they came back to the starting point in a cluster. The spectators cheered; there was something of a spectacle in the sight of these great cars rushing along together, booming like artillery all the while. Mr. Girling did better on the second try than the first time, and Mr. J. Hargreaves also quickened his pace, the result of the two tests being as follows:—

	1st Try. secs.	2nd Try. secs.
S. F. Edge (Napier)	39	39
C. Earp (Napier)	42	42⅜
S. Girling (Wolseley)	44⅛	43
C. Jarrott (Wolseley)	45⅜	45⅜
A. Rawlinson (Darracq)	46⅗	48⅜
C. Muir (Wolseley)	47	47
J. W. Stocks (Napier)	47⅛	48⅛
J. Hargreaves (Napier)	49⅜	47⅜

The acceleration test, taken in the second round over two hundred measured yards, from a standing start, resulted as follows:—

Stocks—18⅗th secs.
Hargreaves—18⅛ secs.
Earp—15 secs.
Campbell Muir—18⅜ secs.
Edge—15 secs.
Girling—17⅛ secs.
Jarrott—17⅜ secs.
Rawlinson—18 secs.

The Accident to Earp.

It was then that the terrible event occurred which led to the abandonment of the contest—it had been intended to have had three runs. On the return it was seen that the drivers were not satisfied with the single file order of running. There was little

Digitized by Google

doubt that, contrary to all intentions of the officials, racing was being indulged in. As they passed by those of us who were standing on the starting line it was apparent that a collision might easily take place, or a dash for the barrier result in scores of spectators being mown down. Neither contingency occurred, but Mr. Earp, realising all too late the speed he was travelling, put his brakes on as hard as possible. He skidded at least sixty yards and then dashed into the wall, being thrown to the ground. The bonnet was projected a distance of a dozen feet to the right, Mr. Campbell Muir, whose car was behind the broken Napier, getting the impression that it was rent in twain. Having made indentations in the wall the vehicle was jerked thirty feet to the left, stopping at the kerbstone as shown in the illustration. The mechanician, Arthur Earp, a brother of the driver, was hurled another twenty feet, and lay unconscious. Within a few seconds he appeared as though in a pool of blood, and, in great agony, was removed to the hospital with his brother and a spectator, whose injuries proved less severe. The car looked a wreck, and the event led to a dispersal of the crowd, whose orderly and silent departure showed how deep had been the impression left by the sad accident. Various surmises have been made as to the cause of the accident, and the supposition that the driver of No. 6 dashed into the wall to

Messrs. H. Austin and C. Jarrett Conferring in Ramsey Control.
Photo by [*T. H. Medwood.*

avoid the people at the other end of the barrier seems a possible one. But had the barrier been made at a greater distance the mishap would not have occurred—a sufficient warning to the organisers of future speed contests to leave sufficient room in which competitors may stop, and also to prevent racing against the rules and regulations. Discipline is as necessary on a motor track as on the review field.

Mr. Clifford Earp has since been able to give his version of the accident. When returning to take up his position for the third test run he says he put his side brakes on very hard with a view to stopping the car. The application of the brakes caused the wheels to lock, and the car skidded. To correct the skidding he attempted to take off the brakes; but, owing to some defect, he was unable to do so, and the car crashed into the wall. Just before the tests he had a slight accident with a part of the brake gear, and he had remedied this with wire, but it failed to withstand the strain. It is a curious coincidence that this was the car upon which Mr. Jarrott met with his accident in last year's Gordon Bennett race in Ireland, and that it has twice since been in accidents.

Latest news from Douglas is to the effect that Mr. Clifford Earp has been discharged from the hospital, and that his brother will only be detained a few days longer.

THE WINNING TEAM.

Late on Thursday afternoon the results of the tests were announced as follows:—

Mr. S. F. Edge (Napier), 1st.
Mr. S. Girling (Wolseley), 2nd.
Mr. C. Jarrott (Wolseley), 3rd.

Messrs. Stocks and Hargreaves were announced as the reserves,

Mr. Clifford Earp on Snaefell.
Photo by [*R. O. Ryan.*

and the judges added the comment that Mr. C. Earp would have been given second place but for the mishap at the close of the trials.

MR. EDGE'S PROTEST.

When the result was posted in the Peveril Hotel at Douglas, conversation was quickly monopolised by the decision of the committee to omit Mr. Earp from the trio of international competitors. No one grudged Mr. Jarrott his place, for his sportsmanlike character and his splendid driving have made him a favourite in such matters. But ere the doctors had completely diagnosed the condition of the injured men, or anyone had made an official inspection of the car, the driver of number 6 was disqualified. This appeared like panic legislation, and

Overhauling Mr. Campbell Muir's Wolseley in Ramsey Control.

was generally denounced as such. We had been assured earlier in the week by the Hon. Press Secretary that the results would be unobtainable until all the officials were back in London, and yet, within two hours of the stoppage of the last event, the selection committee had misplaced the second best competitor because of his mishap. The rumours as to a possible protest soon materialised into actual fact, and Mr. S. F. Edge's letter to the A.C.G.B.I., written on Monday, contains the following statement:—"The trials

Digitized by Google

were, I understood, held for the purpose of finding out the three best drivers and cars in combination to represent England in the Gordon Bennett race, and the finding of the committee is that a Napier car, No. 9, driven by myself, is the best combination, and No. 6, driven by Mr. Clifford Earp, second best. This being the case, I fail utterly to see how any subsequent question affects the point at issue, providing Mr. Earp and his car are

At the Bungalow on Snaefell.

Photo by] [*R. C. Ryan.*

able to race at Homburg on June 17th, and until the committee have satisfied themselves that he will be unable to do this, my contention is that they are entitled to be second in the British team. Mr. Earp's car will be on the road again in perfect condition in a few days, and he himself ready to drive it. There is no doubt that your committee are now aware that the accident to him and his car is comparatively slight. I trust that your committee will give the most serious consideration to my protest, as Great Britain will have quite hard enough battle to fight without its second best competitor being eliminated through what appears to be a panic decision which was come to a very short time after Mr. Earp's accident, when the most incorrect reports in regard to his accident were current; and I contend, Sir, that if it is the intention of the Races Committee that the proved best British cars should represent Britain, then Mr. Earp must be included, as he is entitled to by his performance, as the committee themselves admit." Mr. Edge is now awaiting a reply to his communication.

The Palmer Tyres.

As we mentioned last week, there was considerable surprise at Quarter Bridge when it was seen that Earp's car was fitted with Palmer cord tyres, and motorists naturally followed their career with interest. They behaved splendidly, and the fact that the Napier thus equipped made such fast times both in the hill-climb and in the speed test was significant. During the arduous eight hours' trial the driver evidently felt the utmost confidence in his tyres, which elicited warm praise as they continued their circuits without damage or apparent wear. Their behaviour on such an important occasion is all the more noteworthy as they were ordinary selections from stock, and were not specially made for racing.

The Darracq Disappointment.

Mr. A. Rawlinson, upon whom the hopes of the Darracq "stable" depended after Hemery's and Edmond's wild starts, had cruel luck, and it was fortunate for him that the mishap that put him out of the race a hundred yards from the start did not occur when rounding a corner. His determined efforts throughout were worthy a better result, and much sympathy has been expressed by motoring friends that he had not the opportunity of making a good show. A few minutes before the hour of starting he had trouble with his petrol, and in stripping the cars to get them within the required weight much had to be jeopardised.

The Policy Towards the Press.

As the trials progressed the attitude of the Club towards the Press improved. Little was done to facilitate the work of the special correspondents, and it was quite by accident that we learned of the appointment of Earl Russell as Press Secretary. But the appointment did not carry knowledge with it, and his lordship had frequently to confess that he was unable to give the Press what the public desired to know. The result was that on the eventful day we were left to our own resources in order to secure some idea of the performances of the various cars. By timing at Quarter Bridge, at Ramsey, and on Snaefell mountain we were able to check the times as obtained unofficially by the Press representatives, and thus gave the table of times published in our last issue. The fact that they were thus circumvented was not lost upon the judges, who must have experienced a shock when, on the occasion of the Ramsey hill climb, the timekeepers, who were stationed at the top of the hill, with a courtesy that was refreshing, allowed us to have the times of the arrival of the cars. Equal courtesy was found at the bottom of the hill, and by a simple process of subtraction the results recorded in the *Journal* last week were obtained. Seeing that secrecy was impossible, the times were then given out by the Press Secretary. On the following day the Club officials did what they ought to have done in connection with each event, viz., made written announcement of the results of the speed test. Fortunately, the weather was charming, and the island delightful—two ample compensations for the difficulties that had to be encountered in supplying the public with news of what was transpiring in the Isle of Man.

The Lord Chief Justice, Mr. Justice Wills and Mr. Justice Kennedy have delivered a unanimous judgment in Mr. Clifford's case, where he was convicted for driving a motor car under Clause one of the Motor-Car Act, 1903, at Loughborough. There was a unanimous judgment ordering the conviction to be quashed. Mr. Horace Avory, K.C., and Mr. Moresby White (instructed by Messrs. Firth and Co.) appeared for Mr. Clifford.

A quarterly 100 miles non-stop trial of the A.C.G.B.I. was held on Friday of last week, a 18-h.p. 4-cylinder 4-seated Siddeley car, being the only entry. The quantity of petroleum spirit used on the journey was 4 gallons 3qt 1pt. 10oz. Quantity of water used on journey—1 gallon 12oz. The average cost of fuel per mile at 1s. 3d. per gallon was equvalent to ·47d. A speed up to the legal-limit was obtained and the car climbed Dashwood and Aston Hills in good style.

GLASGOW TO LONDON.

ON Thursday of this week the Reliability Trials from Glasgow to London, organised by the western section of the Scottish Automobile Club, commenced. About thirty vehicles started from St. Vincent Street, Glasgow, at 5.30 a.m., and journeyed southward *via* Douglas Mill, Beattock, Gretna Green, Penrith, Kendal, Kirkby Lonsdale, Skipton and Ilkley to Leeds, the minimum time allowed for all classes being 11 hours 54 minutes, the maximum for class A being 19 hours 9 minutes, and for B, C, and D 14 hours 18 minutes.

On Friday, the 20th inst., the start from Leeds is announced for six o'clock from the Queen's Hotel. A halt will be made at Stamford for luncheon, when engines may be stopped. At Woodcock Hill, Elstree, there will be a hill-climbing contest from a standing start. The route will be *via* Doncaster, Newark, Grantham, Stamford, Biggleswade, Hitchin, St. Albans, Elstree, Barnet and London. All the cars will be allowed a minimum time of 11 hours for the journey; those in class A a maximum of nearly 18 hours, and in classes B, C, and D of 13 hours 12 minutes.

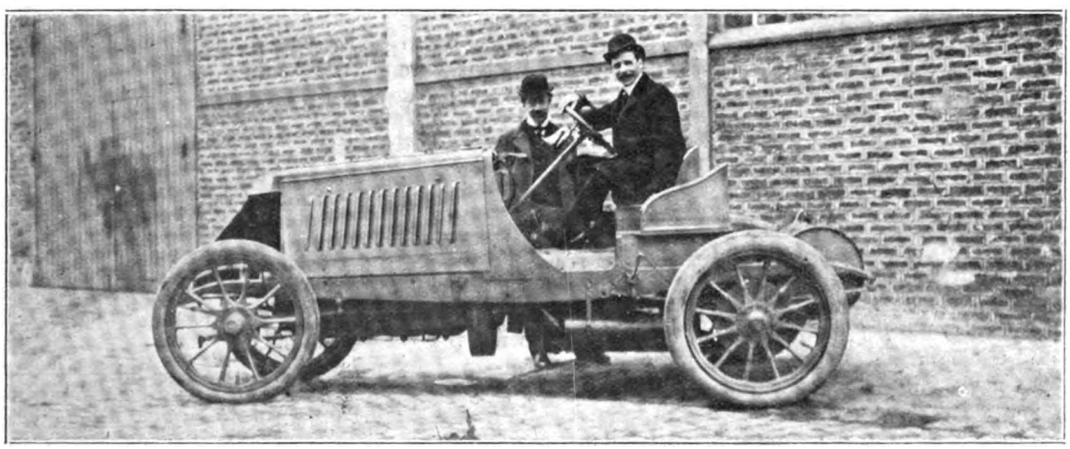
As already announced, the principle underlying the rules is that the trial is one of reliability and not of speed, and the times fixed have been allotted with due regard to the legal limit of speed as well as the nature of the roads in the towns and villages to be traversed, and the reasonable requirements of the public.

Mr. R. J. Smith, the Secretary of the Scottish Club, is acting as honorary secretary of the trials, and the way in which he has arranged all preliminaries leads to the anticipation that the test will prove a really satisfactory one.

To learn the route and just to see what their 8½-h.p. Humber car would do, the makers sent it up to Glasgow on Saturday morning by train, and ran it through from Glasgow on Sunday. They started at 5 a.m. from the Scottish city and reached Beeston at 8.30 the same night. With the exception of three punctures and short stops for meals *en route*, the car had practically a non-stop run, never touching any parts of the car from start to finish.

THE report of the Bedford Highways Committee shows that fifty-six motor-cars and 174 motor-cycles have been registered and 290 drivers' licences have been granted in that county.

THE Crosby Motor and Engineering Company, Limited, has been registered with a capital of £2,000 to carry on the business of makers and dealers in motors, etc. Mr. S. F. Wall is the first managing director.



AT the next meeting of the Highways Committee of the Surrey County Council the question of supporting a petition to the London and South-Western Railway Company, asking them to inaugurate a service of motor-omnibuses between Farnham and Haslemere, will be considered.

GORDON BENNETT RACE NOTES.

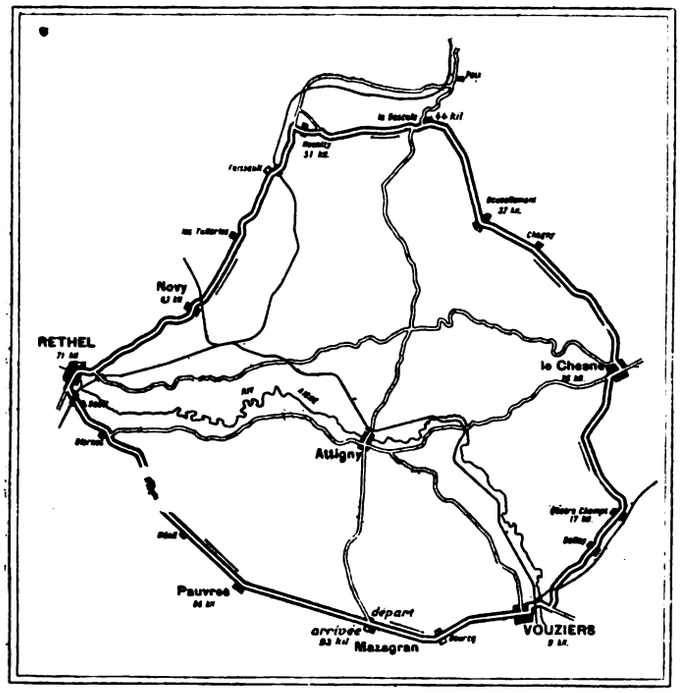
THE following is a copy of a letter which has been forwarded by the German Automobile Club to the A.C.G.B.I.:—"We beg to draw attention to the fact that the approval of the authorities for the Gordon Bennett race to be held on the road between Saalburg, Weilburg, Limburg, Idstein, Oberursel, and Saalburg, only applies to the race course; and that, therefore, the necessary precautions for the avoidance of accidents—especially with regard to the barricading of roads—can only be taken on the actual day of the race. Accordingly, the competitors should only make use of the course beforehand while conforming strictly to the police regulations. We ask you to point out that accidents which might happen during the preparatory training on the course might not only incur the withdrawal of permission to drive over the course, but might also cause the authorities to forbid any subsequent races to be held on public roads. Accordingly, it is absolutely necessary, in the interests of automobilism, to remind competitors and others that they should exercise very great caution when driving over the course.

◆ ◆ ◆

As already mentioned in the *Journal*, all cars entering Germany for the Gordon Bennett Race will have to bear a specially designed metal plate, bearing a registered number and the letters "G. B." The German Automobile Club has forwarded to the A.C.G.B.I. a supply of these plaques for the use of British automobilists who intend visiting Germany with their cars to witness the race. The price of the plaques is fixed at 1s. 6d. each, and as it is essential for all motor-vehicles entering the country to be provided with a plaque, the German Club has requested the A.C.G.B.I. to distribute them at the price stated, to non-members as well as to members. Before a plaque can be issued, however, it is necessary, under any circumstances, for the owner to apply to the Club Secretary for a special form, which must be filled up and signed. The German police have received instructions to render every possible assistance to owners of cars bearing the special plaques, which can only be supplied up to the 20th inst., when a list of those to whom plaques have been distributed must be sent to the German Club.

Mr. Henry Farman on his Panhard Racer.

◆ ◆ ◆



THE Gordon Bennett International Race Committee has decided that the competitors shall be despatched at seven minute intervals. The result of the race will be known on the evening of the race, but will not be officially announced until the banquet at Homburg on the 18th June. The day of the Cup race is to be a general holiday in the districts passed through, by order of the Kaiser.

◆ ◆ ◆

NO news is as yet available with regard to the cars for the Austrian team. They are to be driven by Messrs. Warden, Werner, and Braun. The two first named are now in Vienna, awaiting the completion of the racers.

Digitized by Google

No definite information is available with regard to the American team for the Cup race. According to the last mail the Hewitt and Sampson entries had been withdrawn, that of the Peerless Company only remaining out of the original list. The new competitors are the Bullet No. 2 of the Winton Company and a car built by Mr. W. Christie, of New York. The latter is president of the Christie Ironworks, and is known as the inventor of the mechanism used in revolving the turrets on American battleships. The racing car he has entered is of original con-

The Course for the French Eliminating Trials.

struction, the motor being in the extreme front of the vehicle and the drive being direct on to the front wheels. The car competed in the recent speed trials on the Ormond Beach, Florida, and, considering the fact that its machinery was new and that it was its first trial, it performed very creditably. Although rated at but 30-h.p. it made two successive official mile trials in 1 min. 1 1-5 sec. and 1 min., while in a ten-mile invitation race the distance was covered in 9 min. 35 sec.

◆ ◆ ◆

SOME mystery surrounds the method by which the A.C.A. will select the team. On the 4th inst. a deputation from the Racing Committee of the A.C.A. left New York for Cleveland to inspect the Winton Bullet and the Peerless car, and to subject them to speed trials in order that their fitness or otherwise for the trying ordeal may be demonstrated. An opinion is being freely expressed in motoring circles in New York in favour of the A.C.A. not sending a team to represent the United States in the big race unless the tests prove beyond doubt that the candidates can go the distance and stand the strain, not only of continuous high speed, but of the many stops and fresh starts the German course will entail.

◆ ◆ ◆

FOLLOWING his reinstatement by the American Automobile Association comes the announcement that Barney Oldfield has again been engaged by the Winton Motor Carriage Company, and that it is probable he will drive the Bullet No. 2 in the international race, if the vehicle is accepted as one of the American team.

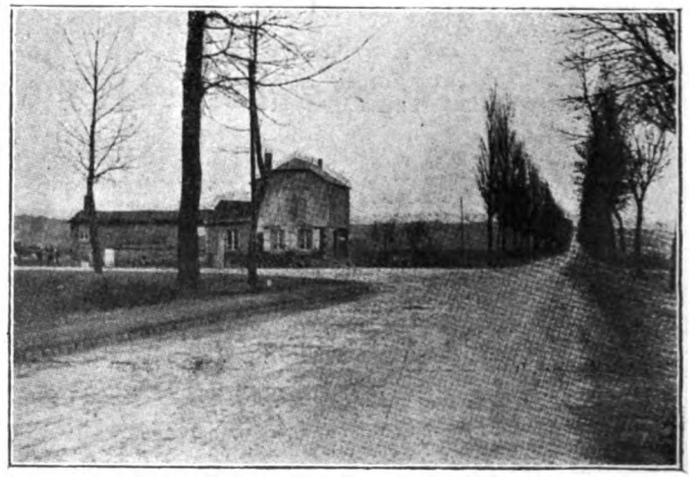
◆ ◆ ◆

BY the time these notes are read the great Eliminating Race to select three cars for the French team for the Gordon Bennett race out of the twenty-nine vehicles that have been specially built will be in full swing, the start being fixed for 5 a.m. on Friday, the 20th inst. The route has already been given in the *Journal*, but the following table of distances may be interesting. The course has, it may be added, to be covered six times.

	Intermediate distance. Kil.	Total distance. Kil.
Mazagran		
Vouziers (n)	9½	9½
Le Chesne (n)	16⅝	25⅛
Cretes de Neuvizy	26 1/16	51 3/16
Novy Chevrieres (n)	10⅜	62 5/16
Rethel (n)	10 3/16	72⅝
Mazagran	21	93⅝

N. Neutralisation.

◆ ◆ ◆



EVERY precaution is being taken to prevent accidents, but, to meet any emergency, six ambulance stations are being established along the course, while no less than 5,000 soldiers have been detailed for duty to keep the roads clear. Over thirty tons of Westrumite has been used in sprinkling the route in order to lay the dust as much as possible. The French Government has established telegraph and telephone offices at Mazagran.

◆ ◆ ◆

THE new Panhard racers somewhat resemble, in outward appearance, a racing yacht, the body being much larger in front than at the stern. The water tank is placed in front of the dash board instead of at the rear. The leather clutch has been abandoned for one of the metal to metal type of much smaller dimensions and working in an oil bath supplied from the engine crank chamber. The drivers will be seated very low down, and practically hidden, as in last year's Mors. The motor develops 20-h.p. more than last year's Panhard racer—that is to say, it gives 100-h.p. at 800 revolutions. The stroke is the same as previously, but the bore has been increased to equal the stroke. The ignition is by Eisemann magneto, but to facilitate starting two accumulators have been coupled and branched on to the magneto cam. The change speed gear gives four speeds forward and a reverse with direct drive on the fourth. As has already been stated in the *Journal*, the transmission is by cardan shaft on to a live axle.

◆ ◆ ◆

THE illustration on page 259 shows Mr. Henry Farman on the Panhard he will drive in Friday's race. In the course of an interview with him he informed us that he is very pleased with the car, which he considers one of the best ever built by the Panhard Co. The car gives an average speed of 30 to 40 kilometres more per hour than that of last year; it takes hills splendidly, and altogether he has no fault whatever to find

A Right Angle Turn near Vouziers, on the French Eliminating Course.

with it. Mr. Farman is no novice at motor-racing, and prior to his appearance on the car was a very successful cycle racer. His first automobile success was the winning of the Pau 150 kilometre race in February, 1901, on which occasion he drove a 2-cylinder Darracq at an average speed of 60 kilometres an hour. Since then he has participated in the Paris-Berlin Race in 1901, Paris-Vienna 1902, and Paris-Madrid and the Gordon Bennett race in Ireland in 1903.

THE "CREMORNE" STEAM CAR.

WE are this week able to give some particulars of the new steam car built by the Cremorne Motor Manufacturing Company, and which made its *debut* at the recent Show at the Agricultural Hall. The vehicle has been designed to meet the demand for a smooth running, reliable car, using paraffin oil as fuel, and shod with solid tyres.

The boiler is located in the fore part of a channel steel frame; it is of the ordinary fire-tube type with seamless steel shell, which in this large size has been found in actual practice to be economical, durable, and to require little attention, besides being a quick steam raiser, and holding a big reserve of power always at command for hill-climbing. It has a heating surface of 110 square feet and is tested up to a pressure of 750 pounds per square inch, and is fitted with a two-headed safely valve. The steam, on issuing from the boiler, is passed through a drying and superheating coil on its way to the engine; thus no condensation of the steam takes place in the cylinder, and full use is made of the heat in the burnt gases. The burner used is the Cremorne Company's well-known type; it is of simple construction, with an absence of wearing parts, and is claimed not to smoke, smell, fire back or clog up, although using ordinary paraffin or lamp oil. The fire is started by means of methylated spirit, and it is claimed that from 250 to 300 pounds pressure of steam can be obtained within ten minutes of lighting up. It is provided with an automatic controller which regulates the burner flame indirectly in proportion to the steam pressure, thus maintaining a normal and constant head of steam. When a steam pressure of 250 pounds is reached the fire is automatically shut down.

The tanks containing both the water and the oil are enclosed, and provided with baffle plates to prevent surging and splashing when the car is in motion. A strainer is placed in a convenient position on both the water and oil pipes to ensure the collection of all dirt and foreign matter; it is designed so that each can be cleaned and replaced within three minutes. The water is pumped from the tank, through its strainer and the feed heater, into the boiler, unless the bye pass is open, when it is returned direct back to the tank. The oil is pumped from its tank through a strainer into a pressure tank, which feeds the burner with oil under pressure; a relief valve is fitted which opens when the pressure in the tank reaches a predetermined amount, the oil being then returned to the tank.

The engine consists of four single-acting cylinders, $3\frac{1}{4}$ in. bore by 5 in. stroke, developing 25-h.p.; the cylinders are cast in pairs, a single valve operating each pair, and one eccentric operating both valves. The gear used allows of a variable cut off, and, therefore, variable expansion, this being obtained at the will of the driver. From this it will be seen that the engine is of simple construction, as well as economical and efficient. There are no glands to work loose and to require packing continually. One lever controls the speed and the operations of starting, reversing and stopping. The water, oil and return water pumps

are driven by the engine, being enclosed together in an oil and dust-proof casing. The pumps' valves, however, are situated conveniently for inspection at all times. A positive and mechanical lubricator is provided for the valve chests and cylinders, this discharging a minute portion of lubricant continuously into the steam pipe, the method of operation providing for an increased amount of lubricant on starting and for hill-climbing. The drive from the engine shaft is by a single chain on to the back axle, on which a differential gear of the spur wheel type is mounted. The exhaust from the engine passes through, firstly, a separator, which takes from it any oil that it has brought with it from the engine. It then passes through the feed heater, giving up a great proportion of its remaining heat to the feed water on its way to the boiler. After passing through the condensers, where it is condensed back into water, it passes through another separator, where any steam still uncondensed escapes, the water being pumped by the return water pump back into the tank, passing on its way through a filter, which thoroughly cleanses it. When the engine is running at 600 revolutions per minute, the car can attain a speed of twenty miles per hour. A clutch is fitted to the sprocket on the engine so that the latter may be run for a few minutes before starting out on a journey. Coming now to the control of the vehicle; upon the dashboard in front of the driver are the steam pressure, oil pressure, and water level gauges and the main steam throttle valve. At his right hand are the reverse lever, the hand brake and the water bye-pass valve. In front of him is the inclined steering wheel, to which the horn is attached. His right foot rests upon the brake pedal and the left foot upon the auxiliary steam throttle valve, by which the speed of the car can be instantly and momentarily controlled.

Figs. 3 and 4.—Part Sectional Front and Side Elevations of the Cremorne Steam Car.

The reverse lever controls the speed of the car. This, however, is only within limits, as it operates by varying the cut off in the cylinders; so, in practice, when the reverse lever has been placed in the notch to keep the car at a speed of say between ten and fifteen miles per hour the speed of the vehicle is then controlled by the left foot, which slows the car down for traffic, for passing obstructions, for cross roads, or for corners, until it is desired to alter the speed of the car to say five to eight miles per hour, or perhaps twenty-five to thirty miles per hour, when the reverse lever is again brought into action. In practice, the reverse lever is but rarely used, the driver controlling the speed of the car entirely with his left foot.

Solid rubber tyres with wood wheels of the artillery type are used, but a smooth motion is ensured by the use of extra long and heavy double springs and a long wheel base. The axles, springs, and wheels are of specially strong construction to withstand road shocks, no attempt having been made to cut down the weight of these members. The brakes are of the metal to metal type, and act equally efficiently whether the car is running backwards or forwards. Three are provided, one on each rear road wheel, and one on the differential. The engine itself can, of course, at any time be used as a brake. The steering is irreversible, and means of adjustment are provided to take up any wear. The fuel tank has a capacity of 15 gallons, while 28 gallons of water can be carried, these quantities being sufficient for a run of 100 miles. Fig. 1 shows a side entrance double phaeton to which a detachable brougham top can be fitted. The *chassis* of the car weighs 18 cwt.; it is also made slightly heavier when intended to receive a van body capable of carrying up to two tons.

MOTOR-CYCLING NEWS.

No less than seventy entries have been received for the Motor-Cycling Club's run to Edinburgh, the start of which is fixed for 10 p.m. on Friday, the 20th inst.

THE annual motor-racing and cycling meeting of the Midland Cycling and Athletic Club was held on Saturday at the Aston Villa grounds. The feature of the afternoon was the motor-bicycle racing. T. A. Tessier, on a Bat, covered the five miles in 7 min. 22 2-5 sec., and E. R. Collier, on a Matchless, won the two miles race with a time of 2 min. 47 2-5 sec.

FROM Messrs. Brown Bros., Limited, comes a copy of the booklet on the Brown motor-bicycle they have recently issued. It gives a very full description of the machine, the various parts being clearly illustrated, and, in order to further assist users of these motor-cycles, the function of each part is fully explained. The illustrations include large size views of the engine and diagrams showing attachment of Longuemare carburetter, wiring, etc.

THE Southern Motor Club's one hundred mile reliability trial has resulted in the first prize (a silver cup) being won by H. C. Bygrave (2¾-h.p. Crypto), and the second by C. Pattison (3½-h.p. Phœnix). Messrs. May and Larkin also made non-stop runs. The next events organised by the club will be a garden party at the Glyn Arms Hotel, Ewell, on June 20th, and a launch party on Sunday, July 17th, to Marlow.

THE awards have now been made known in regard to the recent Paris-Bordeaux-Paris motor-bicycle reliability trial organised by the Auto-Cycle Club de France. Gold medals have been awarded to the following competing machines:—Bruneau (2), Lurquin-Coudert (2), Werner (2), Minerva (2), Lamaudiere (2), Bonnet (1), Knap (2), Cavelier (1), Stimula (1), Carreau (1), F. N. (1), Alcyon (1), Clement (1). The Doue machine secures a silver medal, while the Boudiot, Van Altena, La Foudre and Gladiator receive honourable mention.

THE hill-climbing competition organised by the Auto-Cycle Club was held on Saturday last in splendid weather. The hill selected, which was on one of the bye-roads beyond Northaw, off the Great North Road, in Hertfordshire, has a length of about 750 yards, the gradients including stretches of 1 in 8 and 1 in 12. The competitors, to the number of about thirty, assembled at Barnet, where the machines were carefully weighed. The competition was confined to touring machines, fully equipped, with the tanks filled with oil and petrol. The machines were classified under four heads, namely:—Class 1: Motor-cycles having a cylinder capacity not exceeding 70 by 70. Class 2: Up to 76 by 76. Class 3: Up to 80 by 80. Class 4: Fore-carriages, side-carriages and trailers, carrying two passengers. Competitors were allowed to pedal up to the starting line only. Only three machines failed to get up the hill, and it was noteworthy that the three fore-carriages made very good times. The committee of the club met afterwards at Barnet and inspected the fastest machines in each class, in order to ascertain that they fully complied with the stipulation that they should be standard touring machines, fully equipped for the road. As there were a few doubtful points which the judges will be called upon to settle, the announcement of the awards was held over.

THE HIGH-TENSION IGNITION SYSTEM FOR PETROL MOTOR-CARS.

By J. W. Frings.

(*Continued from page* 218).

The Contact Breaker.—There are three important varieties of contact breaker—the trembler, the positive make and break, and the wipe, the latter form being that now most generally in use. Its function is to provide a means whereby the flow in the primary circuit, and the high-tension discharge in consequence, may be restricted to the moment when it is desired to produce the ignition spark. This piece of mechanism is frequently, but quite erroneously, referred to as a commutator, an organ of a dynamo, the specific uses of which are to collect, and to rectify the direction of, the generated current. A positive make and break gives, by induction, a single discharge of reversed direction in the secondary circuit, the intensity of which depends upon the rapidity with which the break is made, but it has been found that a series of rapid makes and breaks, giving a continuous alternating discharge through the secondary coil, occasions a larger and hotter spark—really a stream of sparks—at the plug, and ensures ignition with greater certainty even if the mixture of gases be of a less explosive character. To achieve this result a steel blade of fine temper, with platinum contact points, platinum being used on account of its practical infusibility, was caused to vibrate rapidly for the fraction of a second when the current was allowed to pass, by using a disc cam with a segment removed, which for seven-eighths of the period prevented the contact of the points. When contact was made by the cam permitting the tongue to fall into the notch, the spring of the blade gave the necessary trembling movement for the rapid make and break. To maintain a good result it was always necessary to have a very fine adjustment of the blade, a matter of difficulty, as the platinum points pitted and scored, and the blade itself, from the constant hammering, lost some of its temper. Further objections to this type of mechanical trembler were that the wear of the involved parts altered the adjustments, and oil from the crank case frequently prevented the points making sufficiently good contact. In the wipe contact the cam is replaced by a circular disc, and the trembling blade by a stout spring blade which firmly presses on the disc during the whole of the revolution. A segment of the disc is a conductor and in metallic contact with the spindle on which it revolves, this providing the "return" for the circuit. The blade, by pressing on the disc, keeps it clean and free from oil, and the contact is sufficiently long to allow the electrical trembler on the coil ample time for a great number of makes and breaks, in addition to which it has the great advantage of requiring no adjustment whatever.

The Coil Trembler.—The fact that the core of the induction coil becomes a powerful electro-magnet at the moment that the current is passing has already been alluded to. This is taken advantage of by constructing the trembler as an armature—a piece of soft iron subjected to the action of a magnetic field to produce mechanical motion in the following manner. The connections of the primary circuit are so made that the path through which it must complete its circuit includes a steel spring, to which the iron armature is attached. At the moment that contact is made on the disc the platinum points on the trembler are also in contact, and permit the current to flow, but simultaneously with its flow the core becomes magnetised and attracts the armature. The armature responds to the magnetic attraction, which is greater than that of the spring which holds it in contact. As it moves in obedience to the magnetism it breaks the circuit. Immediately the magnetic attraction ceases, with the cessation of the current, and the spring forces the armature back into contact, only to be immediately re-attracted by the core. A stop piece is provided to limit the movement of the armature to a useful range, and an additional spring is attached to the armature mechanism to assist its return and accelerate the speed at which it works. A stout bridge over the armature carries a milled-headed screw which constitutes one of the contact points, and permits an extremely sensitive adjustment, which, when used in conjunction with a good coil, containing an efficient condenser, requires practically no attention.

The Sparking Plug.—This is a very familiar item of the ignition system, and as its uses have been referred to it will not be necessary to do more than point out some features which a good plug should possess. The body should be so designed as to give ample insulation both longitudinally and transversely. The insulating material should be capable of withstanding great heat and a moderate amount of ill-usage. The nuts to secure the wire—for preference there should be two—should be a good fit without being so tight as to prevent ready removal. The central wire, the conductor, might with advantage be much stouter than is usually the case, and the gap should be capable of simple, certain and efficient adjustment. I have found that a second and even third pole, providing alternative paths for the discharge, produces better results than the single pole plug; the fire area being greater, a more rapid combustion is obtained and the initial pressure on the piston is enhanced. Insufficient external longitudinal insulation is responsible, especially in damp weather, and in motor-cycles—where the plugs are very much exposed—for short circuiting and consequent misfiring, the damp air or the film of moisture on the porcelain providing a path of less resistance than the internal spark gap.

The Wiring.—Both high and low tension wiring should be well insulated, more especially where the frame of the vehicle or machine is used as part of the circuit, for a bare wire here, in the primary conductor, would almost inevitably result in damage to the accumulator by discharging it without the resistance of the coil, and in the case of the high tension wiring, a poorly insulated, or chafed wire, which for neatness of appearance is generally clipped close to the framing, will afford a "short" and so cause misfiring.

The Interruptor.—This is merely a means of conveniently breaking the circuit when the motor is not in use for a considerable period, while the switch is, of course, used for momentary breaks in running the engine. There are several types of switch, the latest and most convenient being that operated by the preliminary movement of applying the brake in a motor-cycle. On a car, the engine is usually kept running during stoppages for short periods, and the switch only used to break the circuit when it is desired to cease running the engine.

The Duke of Connaught and his two daughters were seen on a six-cylinder Napier car on the Surrey roads on Sunday.

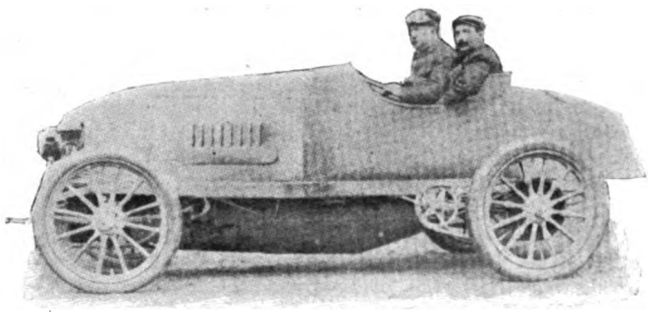
Sir Francis and Lady Jeune went a-motoring on Sunday on a Talbot car driven by Mr. Oliver Stanton.

To the end of April last 265 British-made motor-cycles had this year been exported from this country, their value together with those of "parts" amounting to £12,220.

Copies of the photos taken by Mr. E. Kennard at the Eliminating Trials in the Isle of Man last week can be obtained from the Stereoscopic Company, of 108, Regent Street, London, W.

Messrs. Atkinson and Griffin are opening the Westmorland Garage at 58, Highgate, Kendal, for the Whitsun holidays. They will have accommodation for ten cars, and will also supply petrol and accessories.

The stoppage of Mr. Edge's car in the eight hours' trial in Manxland last week, owing to the firing of the petrol tank by the exhaust, did not exceed two minutes, this being the official timing in the Foxdale control. It is a pity that these official times were not issued to the Press, thus giving correspondents an opportunity of correcting general impressions.



Extensive premises have been acquired by the Brighton and Sussex Moor and Carriage Works at the rear of and immediately adjoining the Grand Hotel and plans have been prepared for the erection of a glass covered Public Garage nearly 70 feet square, or about 5,000 square feet area. Private lock-up storage will also be provided and the whole will be capable of accommodating, without inconvenience, 70 to 80 cars. Provision is also made for ample workshops, with five inspection pits, and a large open yard; the whole being easy of access from the road.

CONTINENTAL NOTES.

Hill Climbing near Vienna.

The annual hill climb on the Exelberg, organised by the Austrian Automobile Club, was held on the 8th inst. The length of the course was 4 1-5 kilometres, and this was covered by Hieronymous on a Spitz car with 60-h.p. Mercedes motor in 4 minutes 29 2-5 seconds, he thus not only being first in the heavy car class but making the best time of the day. Fritz Opel was first in the voiturette class, climbing the hill on an Opel-Darracq car in 4 minutes 46 4-5 seconds. In the motor-cycles (under 50 kilog.) class, Nikodem on a Puch secured the first

M. Léger on his Mors Racer.

place in 4 minutes 57 1-5 seconds, while Wondrich on a Laurin-Klement headed the heavy motor-cycle category, his time being 7 minutes 38 3-5 seconds.

◆ ◆ ◆

Motor Traction in Denmark.

A commission appointed by the Danish Minister of Public Works is visiting London and Paris with a view of inquiring into the question of employing motor-wagons in place of the horse-drawn vehicles at present used at the ports in Denmark.

◆ ◆ ◆

Track Racing at Frankfort.

In connection with the Gordon Bennett week the Frankfort Automobile Club is organising a race meeting to be held on the Oberforsthaus trotting track, at Frankfort-am-Main, on the 19th, June. One lap of the track is equal to one mile, that is 1,609 metres. The following is the programme of the races. 1.—Motor-cycles; open to amateurs; the machines must be started by pedalling and without assistance from anybody; distance, three miles. 2.—Alcohol competition; open to alcohol-driven cars weighing 400 kilos and over, up to 15-h-p.; to be driven by professionals; besides the driver an adult passenger must ride in the car; distance five miles. 3.—Light cars weighing 400 kilos and over, with one or two-cylinder motors up to 14-h.p. inclusive; open to amateurs; besides the driver, an adult passenger must be carried; distance five miles. 4.—Alcohol competition; large alcohol driven cars weighing over 650 kilos, up to 40-h.p.; open to amateurs; besides the driver a passenger must ride in the car; distance ten miles. 5.—Heavy cars, weighing over 600 kilos, up to 24-h.p. inclusive; open to amateurs; besides the driver, a passenger must be carried; distance, eight miles. 6.—Touring cars over 1,000 kilos, up to 30-h p. inclusive, with complete touring carosserie, for four persons; open to amateurs; besides the driver, a passenger must ride in the car; distance ten miles. 7.—The Peter Cup race, cars weighing over 600 kilos, up to 60-h.p. inclusive: open to amateurs; besides the driver, a passenger must be carried, distance ten miles. Herr Poege at present holds the cup, which must be won twice in succession by the same driver on a German track before it finally lapses into his possession. June 1st is the latest date for entries for the events, full particulars of which can be obtained from the secretary of the Frankfurter Automobil Club, Frankfort-am-Main.

Electric Postal Vans in Paris.

The postal authorities in Paris have adopted a light electric motor-van for the carriage of mails from the post offices to the railway stations. The cars are designed to attain a speed of twelve miles an hour, as compared with the eight miles of the horse-drawn vehicles. The first vehicle, which was constructed by Messrs Mildé and Co., was subjected to a trial a few days ago. It has a carrying capacity of about 12 cwts., while the battery of 44 cells will enable the vehicle to travel about twenty-five miles on one charge. It is stated that fifteen of the vans are shortly to be put into service.

◆ ◆ ◆

An Austrian Motor Volunteer Corps.

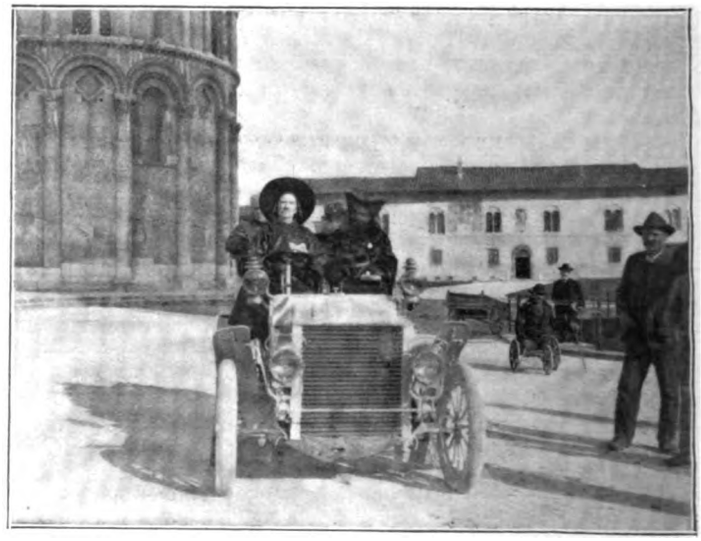
It was announced some time ago that a movement had been inaugurated by the Austrian Automobile Club to organise a Motor Volunteer Corps on the lines of that existing in England. A scheme was drawn up by a commission consisting of members of the A.C.A., the Austrian Motor-Cycle Union, and the Austrian War Office, and this has now received the approval of the Minister of War. It is expected that the new corps will make its debut in the manœuvres in Southern Bohemia in September next, in which ten cars and about twelve motor-cycles are expected to take part.

◆ ◆ ◆

Another Motor-Bicycle Competition.

The "Cote d'Azur Sportive," of Nice, is organising a "criterium" of touring motor-bicycles to be held at the end of the present month. The course will be about 150 kilometres long, starting at Nice and finishing at Cannes. Points will be awarded for (1) regularity of running, (2) consumption of spirit, (3) speed in kilometre trial, (4) hill-climbing capability, and (5) facility of starting and stopping.

◆ ◆ ◆



The Nice Automobile Club House and Garage Burnt Down.

On of the largest fires ever known at Nice occurred early on Sunday morning last in the garage of the Automobile Club, a huge circular building on the Boulevard Gambetta and Promenade des Anglais, which was formerly a panorama and skating rink. The building was completely gutted, and forty cars are reported to have been destroyed, including those of the Duke of Leuchtenberg and Prince Soltykoff. The damage is estimated at upwards of £40,000.

◆ ◆ ◆

A De Dion Excursion in England.

Last year Messrs. De Dion, Bouton, and Co. organised an interesting excursion to the Rhine districts for motorists

A White Steam Car at the foot of the Leaning Tower at Pisa, Italy. Seated in the Car is the "Official Beggar" of the Town.

using De Dion cars. For 1904, arrangements are in hand to organise a similar tour in England. The following is the preliminary programme which has been prepared.

July 10th.—Leave Paris for Calais.
July 11th.—Cars leave Calais on special steamer for Dover.

Digitized by Google

July 12th.—Departure of motorists at 1 a.m. for Dover, and run to Tunbridge Wells.
July 13th.—Run from Tunbridge Wells to Portsmouth.
July 14.—Visit to the Isle of Wight.
July 15.—Portsmouth to Bournemouth *via* Andover and Salisbury.
July 16.—Bournemouth to Torquay.
July 17.—Torquay to Plymouth.
July 18 and 19.—Runs into Cornwall from Plymouth.
July 20.—Run to Barnstaple.
July 21.—Barnstaple to Bristol.
July 22.—Bristol to Oxford.
July 23.—Oxford to London *via* Windsor.
July 24 and 25.—London.
July 26.—Return to France.

The tour will altogether extend to about 750 miles.

◆ ◆ ◆

A Military Motor-cycle Relay Race in France.

Good progress is being made with the organisation of the military motor-cycle relay ride from Brest to Belfort, a distance of about 1,000 kilometres, which is to be held in the latter half of July. At a meeting last week it was decided that there should be eleven relays, each of which is to be undertaken by a different type of machine. The various stages and the machines allotted thereto are shown below.

Stage.	Distance.	Machine.
Brest-Louargat	101 kilometres.	F.N.
Louargat-Broons	92 ,,	Alcyon.
Broons-Vétré	90 ,,	La Française.
Vitré-Pre-en-Paille ...	100 ,,	Werner.
Pré-en-Paille-Tillieres ...	110 ,,	Gladiator.
Tillieres-Paris	105 ,,	Clement.
Paris-Chateau-Thierry ...	99 ,,	Griffon.
Chateau-Thierry-Couvrot	108 ,,	Lurquin-Coudert.
Couvrot-Jouy	110 ,,	Georgia Knap.
Jouy-Arches	112 ,,	Cottereau.
Arches-Belfort	99 ,,	Peugeot.

Trials of Commercial Vehicles in France.

The Technical Committee of the A.C.F. has now published the rules for the trials of commercial vehicles, which are to be held from August 22nd to September 2nd next over a course of about 1,000 kiloms., in the North of France. The trials will comprise four tests—(1) for industrial vehicles, which will be subdivided into tests for (a) passenger service and delivery vans and (b) motor vans and wagons; (2) for electrical touring vehicles and delivery vans; (3) for speed and distance recording devices, which will be attached to the judges' cars; (4) for tyre protecting devices. In the first section will be comprised omnibuses capable of carrying ten passengers with luggage, delivery vans with a load capacity of at least 750 kilos., wagons with a load capacity of at least one ton, and road trains capable of carrying at least twenty passengers, or a load of 2½ tons. The entry fee for each vehicle is 300f., and entries will be received up to August 15th. The Trials will include a fuel consumption test, before the start, which will be made on the level on good roads over a distance of 50 kiloms. for vehicles in the first class, and 30 kiloms. for those in the second category, road trials of about 900 kiloms. for vehicles in the first, and about 650 kiloms. for those in the second class; one or several exhibitions of the vehicles, lasting a day each, in the towns through which the routes for the trials pass; a fuel consumption trial at the close of the road tests similar to that before the start. A jury nominated by the Technical Committee of the A.C.F. will supervise the trials, and will note the regularity of running, fuel consumption, and repairs, which can be made by means of outfits carried on the vehicles themselves, or through the ordinary resources of the country traversed. At each of the nightly stopping places the competing vehicles will be stored under supervision.

◆ ◆ ◆

Baron de Caters' new World's Record.

On Sunday last, on the Ostend-Nieuport road, Baron de Caters made another attempt to lower the world's record for the flying kilometre on his 90-h.p. Mercedes, and succeeded in setting up new figures. Timed by Messrs. de Beukelaer and Rotsaert he covered the kilometre in 23 seconds dead, equal to a speed of almost ninety-eight miles per hour. The previous record, 23 3-5 sec., was made by Rigolly on a Gobron-Brillié.

HERE AND THERE.

—◆—

On Saturday the Burnley and District Automobile Club had a run to Settle.

The Westrumite Company announces that it has now secured orders for its dust-laying solution from nine cities, thirty boroughs, forty-one urban district councils, eight municipalities, and nine metropolitan boroughs.

Dr. O. H. White, of Helsby, near Warrington, is introducing a new sparking plug, of which illustrations are given herewith, Fig. 1 showing a general view and Fig. 2 a section of the complete plug, while Figs. 3 and 4 show the details, from which it will be seen that the spark occurs across the end of the central rod and a point forming part of dome-shaped shell. The advantages claimed

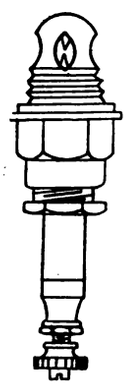

Fig. 1.

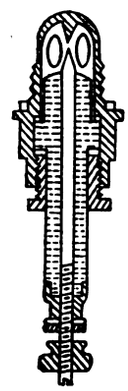

Fig. 2.

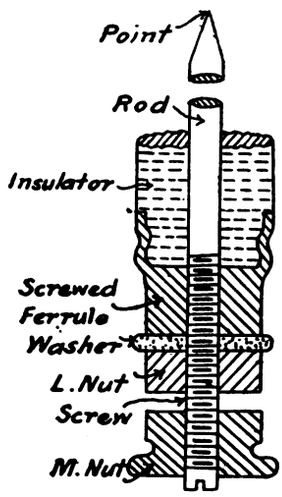

Fig. 3.

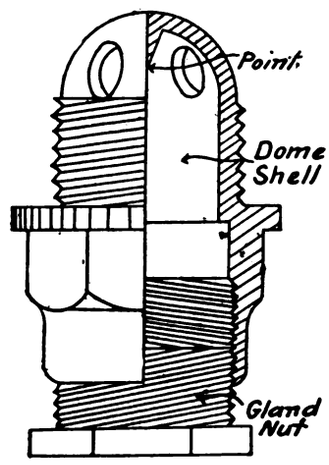

Fig. 4.

for the new plug, which is known as the "Dome," are that it is less liable than the ordinary type to get sooted up, and is easily cleaned by a feather or brush; the points are not affected by vibration and are mechanically protected from injury, while the parts are all adjustable and may be renewed and replaced if necessary.

Quite an invasion of motor-cars is taking place in Ceylon. Mr. R. Davidson, of Colombo, has just imported a 10-h.p. Beaufort car. Mr. R. J. Farquharson, a well-known sportsman, has received a 5-h.p. Humberette. Mr. Ernest Hamilton, of the Dolosbage and Yakdessa Company, is also expecting a 6½ h.p. motor-car from England shortly.

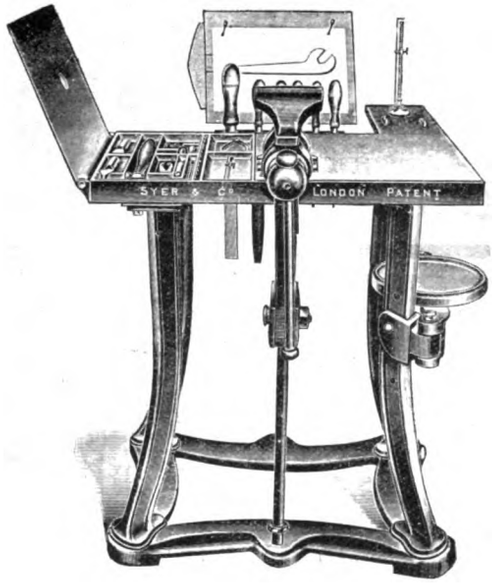
The fortunes of the Cleveland Motor Company, which was formed in Cleveland, U.S.A., last autumn to exploit the automobile inventions of Mr. E. J. Pennington, are at a low ebb, the concern having gone into bankruptcy. The company proposed to manufacture several inventions of Mr. Pennington which it was claimed would revolutionise the automobile industry.

Digitized by Google

WE hear that an automobile club is in course of formation at Westcliff-on-Sea.

MESSRS. FRISWELL, LIMITED, are now issuing a weekly auction catalogue.

WE learn that the E.I.C. sparking plugs were used on the Napier, Wolseley and Darracq cars in the Eliminating Trials in the Isle of Man last week.



THE exports of automobiles and parts from the United States during March last were valued at £33,880, as compared with £18,723 in the same month last year.

MR. C. GUY, who is opening premises at 16, West Street, Reigate, has been appointed official repairer to the East Surrey Automobile Club.

DESPITE unfavourable weather no less than 217 motor vehicles took part in the May Day automobile parade held in New York by the Automobile Club of America on the 30th ult.

SO far twenty-nine entries have been received for the Circuit des Ardennes, which is to be held on the 25th July. No less than six Darracqs will compete in the event.

THE accompanying illustration shows a vice bench which has lately been brought out by Messrs. T. Syer and Co., and which should prove a useful addition to the equipment of the motor-house of those motorists who like to undertake small repairs themselves. As will be seen, it is a small engineers' bench

complete in itself. One half of the table is plain while the other is provided with compartments to hold a range of tools. A file rack is also provided. The illustration shows the bench with a drawing board, as arranged for student's use, and also with a small surface plate with two small V blocks.

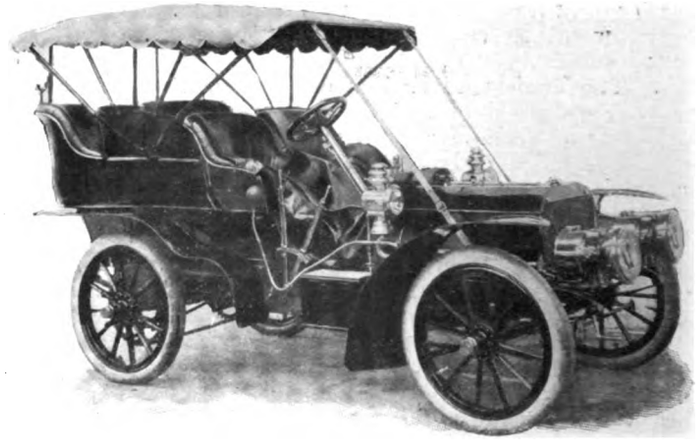
THE Motor Castings Company, of Gray's Inn Road, W.C., are bringing out a 4¼-h.p. motor specially designed for launch work. It is being supplied with a two-bladed propellor to suit a boat of sixteen feet in length.

THE Bristol Motor Company, Limited, has been registered with a capital of £15,000 to acquire the business now carried on at 4 and 5, Redcross Street, and 18, Victoria Street, Bristol, as the Bristol Motor Company.

HARTFORD, Conn., claims to be the first American city to do away with horses and substitute automobiles for police department service. The motor-car equipment, which was installed three years since, now comprises an electric patrol wagon and electric ambulance. The Chief of Police of Hartford states that these vehicles have entirely superseded two horse-drawn patrols, a horse ambulance and a prison van.

THE 1904 edition of the Great Eastern Railway Company's Tourist Guide to the Continent has made its appearance. Among its fresh features are particulars of new tours in the Tyrol, in North Germany and in Norway, Denmark and Sweden, *via* the Royal Mail—Harwich-Hook of Holland route; of tours in the Luther country, and Thuringian and Hartz Mountains; with a series of Continental maps, and a chapter, "Dull Useful Information," giving particulars of the cost of Continental travel.

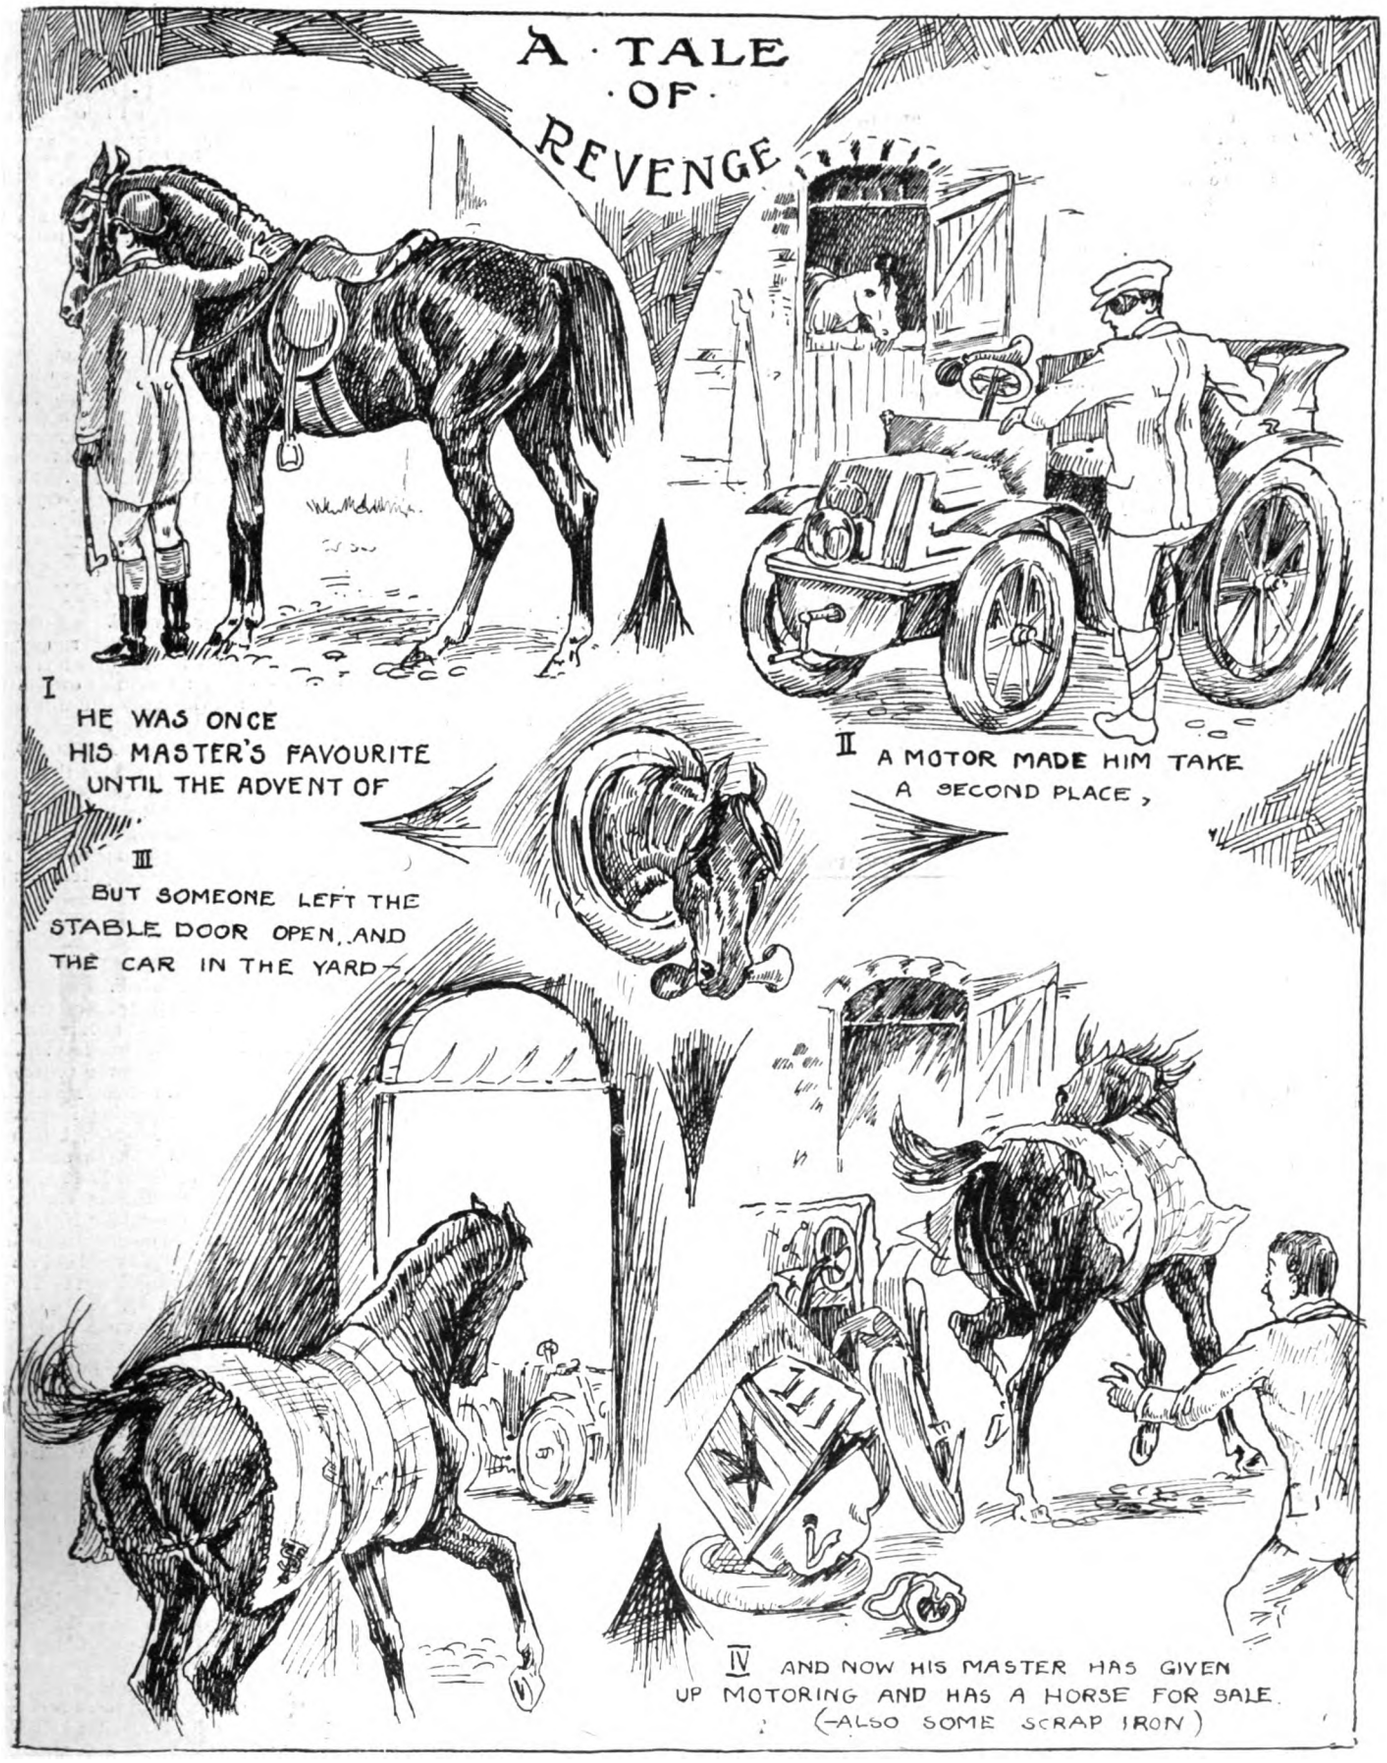
MESSRS. PANHARD AND LEVASSOR have recently issued from their London branch a booklet, a copy of which should be



A 16-20-h.p Argyll Saloon car with side entrance. The vehicle is fitted with a folding down seat between the doors, capable of very comfortably carrying four people inside.

in the hands of all users of Panhard cars. It consists of a price list of spare parts for these cars, ranging from any particular nut up to new cylinders. To assist the motorist in ascertaining the part he requires, illustrations of the majority are given, while, as each has a number allotted to it, it is only necessary to mention this when ordering. Altogether the list is a most useful production.

FROM the Coventry Motor Fittings Company comes their price list for the season, in which special attention is called to the C. M. F. honeycomb radiator, in which a grooved tube, designed to give the maximum cooling surface, has been introduced. A spiral radiator on the thermo-syphon system is also illustrated in this well-arranged catalogue. In the section devoted to lubricators are some good types, including an automatic water pressure lubricator, known as type E. Tanks, bonnets, float feeds, and other accessories also find a place in the list.



THE other day we had an opportunity of going over the Cadogan Garage which has been established in Sidney Street, Chelsea, by the Wilkinson Sword Company, Limited. The garage is most complete, as, in addition to accommodation for about

The above illustration depicts one of the first completed 15-20-h.p. 4-cylinder Brooke cars. The vehicle, which has proved most satisfactory in its trials on the road, is fitted with an elaborate Roi des Belges Body and Cape Cart Hood.

sixty cars, an electrically-operated repairing plant has been installed, while there are no less than five inspection pits available. A large addition to the garage is at present being prepared, in which it is intended to erect lock-up compartments sufficient to accommodate close upon forty private cars. We may add that the garage is open day and night.

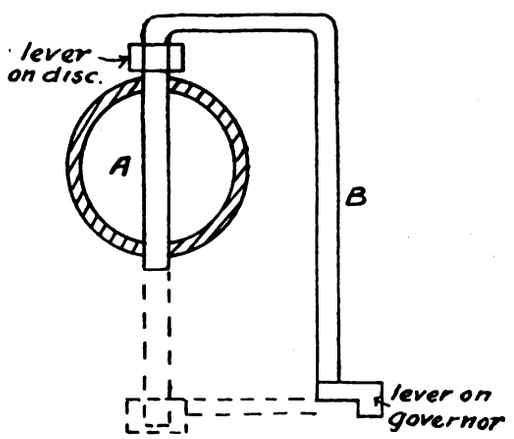
CORRESPONDENCE.

STEAM CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—In answer to the letter of "Lancelot" in the *Journal* of the 14th inst., in which he expresses his astonishment that English engineers have not given more attention to steam, let me call his attention to one English steam car, the Turner-Miesse, which seems to embody all the good points which he asks for in his letter. It is simple, easy to manage, burns paraffin, and certainly is not expensive as compared with petrol cars. Moreover, it is absolutely reliable, and takes any ordinary hill at the same pace as the flat, and I have yet to meet the hill which my car will not take at a good pace in the hilly county in which I reside.



The White is an American car, and, in my judgment, too automatic, and, as your correspondent says, burns petrol (of itself a bad point), and the burner in those I have seen is noisy. The Miesse in my hands, which are not, as yet, those of an expert, costs about ½d. per mile, as near as I have been able to calculate. It seems to me that the Miesse is the car for your other correspondent, "Would-be Motorist." My car is a 6-h.p. and climbs—indeed runs—away up any hill in my district.—Yours truly,

E. H. O. Sankey.

THROTTLE GOVERNING.

To the Editor of *The Motor-Car Journal.*

Sir,—Referring to Mr. J. L. Player's letter in the *Journal* for the 7th inst., I may say that some time ago I had some difficulty with the governor of a 6½-h.p. Aster engine. The governor acted on a disc valve in the inlet pipe; the engine used to run very erratic, but I found that this was not due to the governor, but to the bad principle of connecting the small lever on the governor to the lever on the valve, a small sketch

A. Disc Valve.—Section through Inlet Pipe.
B. Rod connecting the lever from governor rod to lever on disc valve.

of which I enclose. The drawing also shows the alteration made to remedy the trouble. I found, when the engine was working, that the rod B used to sway about in any direction, so in place of this the spindle carrying the disc valve was lengthened downwards as shown dotted, and connected by a short straight lever. This I have found to work very satisfactorily, giving no trouble.—Yours truly,

T. H. J.

DUST SCREENS.

To the Editor of *The Motor-Car Journal.*

Sir,—I am desirous of having a dust screen for the back of tonneau of my car—8-h.p. M.M.C.

The one I have seen and like—"Patent Collapsible"—is four guineas, which seems rather too much to pay. Perhaps you or some of your readers might know of an effective but inexpensive arrangement which would answer the purpose.—Yours truly,

A 184.

CHARGING ACCUMULATORS.

To the Editor of *The Motor-Car Journal.*

Sir,—We have an electric lighting plant in our works from which I should like to be able to charge my 15 ampere-hour ignition accumulator. The installation consists of 150 lamps of 16-c.p. at 100 volts continuous current. The lamps are grouped in sets of ten, *i.e.*, one switch controls ten lamps, and we also have at intervals wall sockets for connecting up extra lamps as required. Should I be safe in taking current from one of these wall sockets to charge my accumulator? Any information you or any readers of the *Journal* can given me on the subject will be greatly appreciated.—Yours truly,

Rallentare.

[It is an easy matter to charge a 15 ampere-hour accumulator from a 100 volt installation, but on no account should the attempt be made to do so from a wall socket, as this would result in connecting 100 volts on to the accumulator, which would probably destroy it in a few moments. All that is necessary is to obtain what is known as a charging adaptor from an electrical firm, and use this from one of the electric lights. A charging adaptor is simply an ordinary lamp holder with a flexible cord attached to it in such a manner that one can charge an accumulator in series with an incandescent lamp. The lamp should beremoved from one of the pendant fittings (inserting the charging adaptor in its place, which it is made to fit), the lamp being put into the holder which is provided on the adaptor. A flexible cord is fixed in the holder, and after testing the two ends of this with pole-finding paper to ascertain which is the + wire, the accumulator should be connected up, taking care to connect the wire from the adaptor to the terminal of the accumulator. The accumulator is charged by the current passing through the lamp and then through the accumulator, the lamp acting as a resistance and preventing too much current flowing through the accumulator.]

MOTOR-CAR INSURANCE.

To the Editor of *The Motor-Car Journal.*

Sir,—I should like a few lines to tell other motorists how well I have been treated by the General Accident Assurance Corporation of Perth. In May of last year I insured a 9-h.p. car. In September I sold the car and bought a 12-h.p. In March of this year I had an accident with the 12-h.p. car, and not having notified the insurance company of the change, I thought they might not pay. I am very pleased to inform you that they paid up without the least hesitation or trouble. Bearing in mind the change of car and that the latter vehicle was very much speedier, etc., I think they acted very liberally.—Yours truly,

Well Satisfied.

THERMO-SYPHON WATER CIRCULATION.

To the Editor of *The Motor-Car Journal.*

Sir,—I would like to ask a few questions as to the thermo-syphon system of water circulation in petrol cars. How is the syphon principle applied to circulate the water in an automobile; that is, how are the water tank and radiating coils located so that this principle will work? Has heat got much to do with its working?—Yours truly,

Petrolius.

[The thermo-syphon system of water circulation is simply the natural circulation. The tanks and radiator are fixed above the level of the cylinder head with the return pipes below the water level. The supply is taken from the bottom of the radiator, or the tank, into the cylinder, and kept circulating by the heat, the hot water passing upward into the top of the radiator; in fact, it may be said that the system depends entirely on the heat for its operation.]

CHAUFFEUR OR DRIVER.

To the Editor of *The Motor-Car Journal.*

Sir,—I append a paragraph which I cut from the pages of a daily paper this week, and which I would like to comment upon, as it is distinctly a gross libel on our profession. It is as follows:—"London is vulgarised by the hundreds of chauffeurs whose Sunday out includes the conveyance on their masters' cars of hordes of hooligans of both sexes. Dressed like tramps, with short black pipes in their mouths, shouting and singing comic songs, these parties invade the West End generally, bringing a most unsavoury odium on the motor-car and all its works and uses." Now, Sir, I beg to state that the gentleman who wrote that had never seen what he describes; the chauffeurs have been accused of a few things, but never, that I know of, of being common, or hooligans smoking black pipes, or dressed like tramps, for as a rule they are much more high-toned, etc., than men in any other profession, and as to the "hooligans of both sexes," it is simply absurd, as when the chauffeur picks up a girl to favour with a ride he always chooses the smartest one he can find, and the whole turn-out is, nine cases out of ten, a smarter and better dressed one than when the owner and his family are on board. Of course, I am not defending chauffeurs who go out "on their own," as the saying is, but I do say they are not open to the insulting abuse of this gentleman of being common and hooliganish, and I think we deserve an apology.

Now, *re* a letter in a recent issue of the *Journal re* the name of chauffeur. Why not? I ask; in France we can use English names for English sports such as yachting and football, etc., without losing any sleep over it, so why not keep the French names for a French sport in England? I guess soon some of our insular Englishmen will be objecting to us Americans calling our language "English" and make us call it "United States," as I have heard done before now at home, and a good thing too; tit for tat.

Now, Sir, if you will grant me yet a little more space I would like to say a word on the question of drivers. The best man on a car is not a "certified" man, valet or otherwise, nor a man who has spent his life at the bench; but a man who has knocked around in all branches of engineering, electrical included, and whenever he gets up against a snag his varied experience in all lines will enable him to get over it; and there are plenty such around. Now, if a man buys a motor-car he wants it available at any hour of the day or night, and sure he wants the chauffeur as well. Let him pay a chauffeur a good wage, and treat him as a man and not a sort of emancipated slave, and in most cases the man will act as if the car were his own, study it and his employer, and get best results, both for his employer and himself, because there are some men still left who can see more

Digitized by Google

than an inch in front of their nose. Why a man of the type I say deserves his wage is, because he can get it at any one branch of knowledge in which he ought to be proficient before having charge of a valuable automobile.—Yours truly,

CHAUFFEUR.

PROPOSED ALTERATION OF BOILER.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I should be greatly obliged if some of your readers would give me some advice as to a Locomobile steam car. I thought of changing the present boiler to one of the flash type, to burn paraffin, if same would be beneficial. At the present time I burn petrol and consume on good roads, with four up, one gallon for nine miles, and require about twenty gallons of water per thirteen miles. What would be the consumption of water and paraffin with a flash boiler, also would the power be as great and as safe ?—Yours truly,

OXON.

PROPOSED SERVICE IN ABERDEENSHIRE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Kindly allow me, through the medium of your valuable *Journal*, to draw the attention of those in authority to the great need that exists for the introduction of a service of motor-cars to ply between Gartly Station and Rhynie, Lumsden, Toll of Mossat, and Strathdon, Aberdeenshire. At present there exists no adequate means of conveyance between these places. From my long connection with and intimate knowledge of the route and the districts enumerated, I am confident that if a suitable service of motor-cars could be introduced and run to suit the principal morning and afternoon trains running to and from Aberdeen and Huntly, etc., in a very short time a considerable volume of traffic, both in passengers and light goods, could be secured.—Yours truly,

M.

CHARGING ACCUMULATORS FROM A DYNAMO.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I notice with pleasure that you are answering queries with regard to the charging of accumulators, and therefore venture to write you on the subject. I have a dynamo generating current at 100 volts, and have got my two wires (having ascertained which is + and —). How many candle-power must I have in the one circuit to charge my four-volt accumulator, which, according to instruction, should be charged at the rate of one ampere for ten hours ?—Yours truly.

F. J. TINSLEY.

[To charge a 4-volt accumulator which requires one ampere for the charging rate, it will be necessary to put two 16 c.p. lamps in the circuit. At 100 volt pressure a 16 c.p. lamp takes ·6 amperes, and therefore two of these will give a trifle over one ampere when the 4-volt accumulator is in circuit. If 16 c.p. lamps are not available, three lamps of 8 c.p. will do; these take about 4 amperes each; or if it is preferable to charge for a long time at a slow rate, two 8 c.p. lamps will be sufficient.]

NUMBERING ALL VEHICLES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I am sending you some paragraphs, as they may interest your readers, showing the different treatment to motorists and drivers of horse drawn vehicles. I think the Automobile Club would be doing a good thing to get an Act passed for carmen to be licensed and the carts to have number plates similar to those on motor-cars. Driving along a country road after dusk one meets carts on the wrong side of the road with no lights and the drivers asleep. If one has not powerful lamps and good judgment there is a collision; a summons follows for reckless driving, the motorist has to pay the piper, while the carman goes on his way rejoicing.—Yours truly,

M. ROBERTS.

QUERIES *RE* MARSHALL CAR.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—I have bought a second-hand (represented as) car of this make, 1902 pattern, but am sorry to say I have not got what I expected. It was advertised as "run 1,200 miles," and I bought it on this understanding and statement; but finding, on tyres getting dry, that they showed a good deal of wear, I made inquiry, and found car was third hand, and had been run 2,000 miles before the seller got it. The covers are Collier's, three of which and the spare (valued 2s. 6d.) are in a very bad state and giving way in long slits next the rim, and I fear ready to burst up any day. I gather that car has run certainly 3,000 miles, and surely covers should not be in such a state with so little wear. As I shall be obliged to get new tyres soon unless I can sell car altogether, I should be glad to have the experiences of others on the subject.

The car is a bad one to drive, and I cannot run it on top speed on the roads in my district; it "picks up" so badly, and cannot do anything of an up-gradient on top gear, and as the roads are always twisting and twining up hill and down hill, I have to crawl on the second, which is a funeral speed only fit for an old woman. It has struck me that lowering the top speed might improve matters, and I wrote the makers. They say they can easily reduce the speed to 25 miles, but they do not say it would actually alter the running, nor did they state cost of same. I wrote them further, but have had no answer, although it is now a good many days ago. People told me it was much better to go in for English-built cars, as there was then no trouble in getting repairs done and obtaining spare parts; some dealers even advertise in this strain, but so far I have not found it to be the case. If you know where to send to abroad you will get spare parts in a few days' time, as they will be in stock; but how many English firms can produce a price list of spare parts, and how many stock such ? I don't know one. I shall be glad of any information on the Collier tyres, and also as to improving the running of the "Marshall."—Yours truly,

AMATEUR.

SOLDERING ALUMINIUM.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Could you tell me of any method by which I can solder or make fast a crack in aluminium ? It is in the base chamber of my motor. I should be glad if you could tell me of any substance with which aluminium can be soldered. Is it at all possible for it to be softened by heat and the crack made up ?—Yours truly,

EDWARD T. WOOD.

[A new solder for aluminium is invented almost weekly, to judge by the numerous recipes appearing in technical journals, but we do not know of any satisfactory one. The usual defect in them is that the joint, sound at first, gradually disintegrates. One of the best formulæ is: tin, 56 parts; lead, 7 parts; zinc, 14 parts; and phosphor tin, 28 parts. It is necessary to use a scratch brush through the melted solder to remove the obstinate film of oxide on the aluminium, and an "automatic" soldering bolt; one of those with a self-contained benzine blow-lamp in the handle, is useful on account of the high conductivity for heat of aluminium. In the case, however, of a cracked base chamber, the best thing would be to rivet a plate over the crack, inside if there is clearance for it, and caulk it outside, if crack is not too wide, with hammer and punch, carefully applied. If the crack is anywhere where mechanical strength is necessary, as we have occasionally seen in the extensions of crank-chamber to carry pump, gear-wheels, or the like, nothing but a bolted or riveted repair is possible.]

BRAKES AND TYRES.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—Replying to "Brake's" letter in your last issue, the best brake and the most reliable consists of a steel band with transverse pieces of brass about half-inch wide riveted on the inside of the band. The oil from gear box or any part of the car has no effect on a brake of this type, as it is immediately burnt off when the brake is in use.

Referring to the latter part of letter *re* tyres, these covers have the straps sewn inside the cover, and there should be one pair of straps for every spoke to make the job a success. This adaptation of old covers is quite a success, and makes punctures almost an impossibility, and very considerably reduces the upkeep of a motor-car.—Yours truly,

THE CAMBRIDGE AUTOCAR CO., LTD.

A DOCTOR'S EXPERIENCE.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—The first few months of ownership of a motor-car, when one is paying for experience, is the most expensive period. After that, not only is the cost of operation reduced, but depreciation also becomes less, because of proper handling. Most of my troubles were due to lack of knowledge rather than to apparent recklessness of driving, and I find that there is much less breakage and strain and the car requires much less repairing and adjusting of parts now than it did during the first few months I owned it.

I have not yet been able to dispense with horses, as I have never been able to fully trust the car. It has broken down and been laid up for minor troubles at different times, which have put it out of use for a number of days. It is like a horse, in that it is ready for business most of the time; yet, while it can easily do the work of three or four horses, a single car will not take the place of two or three horses. If one of your horses is sick, the others can do the work. With the motor-car the same rule must, I think, hold. The physician who decides to use the automobile exclusively must own two machines, so that one will always be in perfect condition. I see in this proposition not only the greatest economy but the greatest degree of comfort, for, with a competent man in the motor-house, only one car is used at a time, and the cost of maintenance is no greater than if one vehicle only were used. Add to this the fact that your two cars will do the work of many horses, yet when they are not in use they are not "eating their heads off," do not require to be exercised and do not add to a man's work. I formerly kept four horses. I now keep two horses and the car for winter's work, and I used but one horse and the car during five months last summer. I mean in another year to own a second car of the same type, and then I shall dispense with horses entirely.

Digitized by Google

With hay-motors I was always on the road, as I have never found a horse that could stand more than fifteen miles of travel per day on the average, and keep in good condition. With the motor-car I have not been obliged to count the miles and have been enabled to cover my entire practice, which usually took me the greater part of the day, in the forenoon. For the busy practitioner the possession of one or two cars under the conditions above indicated will serve the purposes of a conserver of his energy, a saver of his valuable time, an indicator that he is abreast of the times, and will give him the necessary leisure for reading, so difficult to obtain where "hay motors" only are used.—Yours truly,

PROVINCIAL DOCTOR.

THE CARE OF CARS.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—There is all the difference in the world between a well kept car and one which has no regard paid to its appearance. A horse-drawn carriage gets nothing like such hard usage as an automobile, yet it is looked after with an exceeding care, with the object that its outward appearance—its finish, in short—is rarely disreputable and is frequently most creditable. The other day I asked a certain motorist whose car is noted for its well kept appearance for the recipe. He replied:—"The reason why the car looks so well is that I never have a mechanician rubbing it down with oily rags. You see, I know their little ways, and cleaning down with greasy rags will ruin the very best carriage work in a very short time." There is more truth in this than is generally admitted. Paint and varnish are not imperishable. Applied with the utmost care and skill, and subjected to only a minimum of severe weather conditions, they frequently deteriorate deplorably, and are kept bright and glossy only by exceeding care. But the user of a motor-car frequently proceeds on the assumption that no use—scarcely any abuse—is too severe for an automobile. If he looks after the vitals of the car—the engine, transmission, ignition, etc.—he feels that he has done his full duty. The motor-car has not only mud and dust to contend with; in its internal economy oil plays an important part—oil and grease of divers kinds for lubricating, petrol for propulsion—in generous proportions. Ingredients of this kind are life to the metal parts, but death to wood and rubber. A divorce, complete and absolute, should be declared between them, as only in this way can the lustre and longevity of the parts mentioned be maintained.—Yours truly,

LUSTRE.

THE MOTOR-CAR ACT.

TO THE EDITOR OF *The Motor-Car Journal*.

SIR,—The following facts illustrative of the absurdity of the new motor-car regulations will be of interest to many of your readers. Having a contract for the delivery of newspapers on Saturdays throughout London and the suburbs, it will easily be understood the constant stoppings at the various newsagents entail a considerable strain on the car. It is therefore necessary to try any car it is proposed to use for this object to ensure an expeditious and satisfactory delivery. For this purpose a car was tried on the 30th ult. and the trade numbers allotted by the County Council used, resulting in two convictions and two fines, really for the same offence, at the South Western Police Court, one against the driver for using an unregistered motor-car, and whose licence was endorsed to this effect, and the other against myself, as secretary of the Great Central Garage Company, Limited, for unlawfully using an identification mark, and although I was in Paris at the time the offence was committed, my driving licence has also been endorsed with the particulars of the conviction.

As you are aware, a number of endorsements may prevent my obtaining a renewal of a driving licence or it may be taken away altogether without my ever having driven a car at all. Surely a ridiculous anomaly!—Yours truly,

ROBERT NUTSEY.

PARSONS ANTI-SKID CHAINS.—"W. M." writes:—"I shall be glad if someone will tell me if a "Parsons Chain," or other removable anti-skid arrangement, on one driving wheel only of a car will prevent slipping on greasy hills, and this without straining any part of the machinery?"

PETROL IN READING.—Mr. A. H. Harms, of 113, Caversham, Reading, writes that his depot is always open, and that he keeps a stock of charged accumulators, petrol and oil in stock at nominal prices. The Iverna Motor Company, of Abbey Street, Reading, also write to say they are always open on Sundays for the supply of petrol, repairs, and sundries. Their shop is situated in the centre of the town on the main road.

THE LADIES' AUTOMOBILE CLUB.—Replying to Miss E. M. MacGregor, full particulars as to membership of the Ladies' Automobile Club can be obtained by applying to the secretary at Claridge's Hotel, Brook Street, London, W.

TYRE FOUND.—A motor tyre has been found near Huntingdon. Application by the owner should be sent to the Police Station, Huntingdon.

SOME SHORT TRIPS.

BELOW we give some suggested runs of about fifty miles out and home from some of the leading centres of motoring interest. These can be varied according to circumstances; they are only intended to suggest short runs of interest; and we shall be glad to hear from readers able to give alternative routes or propose suitable trips.

CLUBS AND ASSOCIATIONS.

WEST SURREY.

MEMBERS and friends of the West Surrey Automobile Club met at the Hautboy, Ockham, on Saturday, for tea. Among those present were Major Matson, Messrs. Crothers, Praschkauer, Ponsford, Pullman, Vogan, and Buttemer. Several members were reduced to their smaller cars on account of an epidemic of annual overhauls, and the appearance of the Hon. Sec. and his wife on an 1897 Benz gave rise to much mirth. As a result of the efforts of the Club, the road entering Guildford has been treated with Westrumite, and further trials on the other side of the town are being arranged for.

The Meet of the South Lincolnshire Club at Fron Hall, Market Deeping.

LINCOLNSHIRE.

THE members of this club had another very successful meet on Thursday, the 12th inst., when the Red Lion, Boston, was the rendezvous. The club has been singularly fortunate this year as far as the weather is concerned, for every run has been favoured with pleasant sunshine and excellent roads. Amongst the motorists present were Messrs. C. W. Pennell (Lincoln), H. S. White (Lincoln), C. Nelson (Lincoln), Capt. Gleed, J.P. (Donington), W. A. Tomlinson (Sleaford), G. Godson (Asgarby), Rev. R. H. Sampson (East Keal), Rev. M. Watkins (Croft), Leslie Pogson (Sleaford), Dr. White (Swineshead), Dr. Benson (Market Deeping) J. H. Carter (Market Deeping), F. Richardson (Sibsey), Dr. Crompton (Benington), Dr. Miller (Wrangle). Dr. Reckett, C. Holland, and some of the other Boston members were also present.

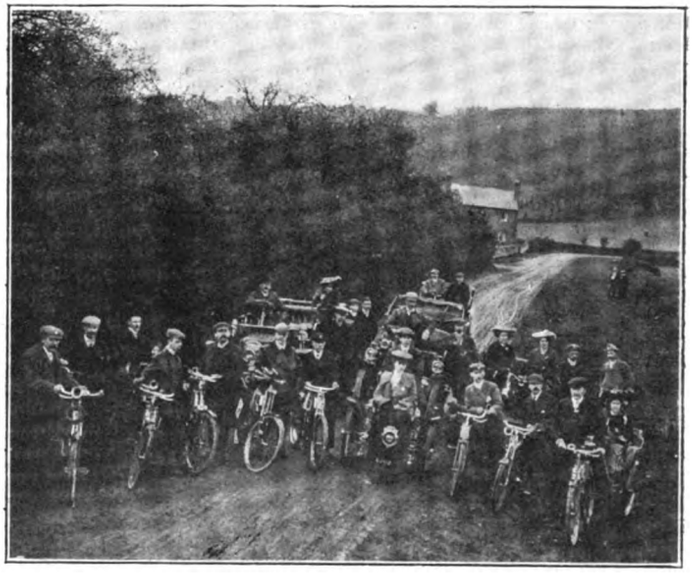
MANCHESTER.

ON Saturday last the Manchester Club run was to old Moreton Hall, and was attended by twenty-two cars, which brought so many members and their friends that the capacity of the dining room was severely taxed. Very great interest was taken in the picturesque old hall, which is situated at the extreme corner of Cheshire off the highway between Congleton and the Potteries, the lofty hill of Mow Cop being its conspicuous landmark. It is a perfect specimen of a half-timbered manor house and is a beautiful example of the Tudor and Jacobean period. Seen from the highway its projecting upper storeys and quaint windows, its gabled roof, and ivyclad chimneys and its walls chequered in black and white, make a charming picture, and cameras were very much in evidence. Before leaving a number of photographs were taken of the cars arranged in a semi-circle by the side of the hall.

LEICESTER.

THE members of the Leicester Automobile Club had their third run of the season on Saturday, when Oakham was visited, the route being by Billesdon and Uppingham. There were fifteen cars and two motor-bicycles, and the spin was a most enjoyable one. Oakham was reached about five o'clock, and tea was provided at the Crown Hotel, thirty-seven being present. Mr. King presided in the absence of the president, Mr. G. E. Mawbey, who, however, was not forgotten, as a telegram was sent to him conveying all kinds of good wishes. A communication was received from Colonel Powell, Melton Mowbray, who requested the club to call upon him on the return journey. After a stroll round the quiet old town a start for home was made at seven o'clock. Melton was reached in good time, and the cars drew up at the residence of Colonel Powell, whose hospitality was enhanced by vivid descriptions of the motor trials in the Isle of Man, from whence he had just returned. Another halt was made at Syston, on the invitation of Mr. Harding. Leicester was reached about 9.30, after a capital run, none of the cars having experienced the slightest mishap. It was a most pleasant outing, the weather being all that could be desired throughout, and every member of the party was in the merriest mood. Those who took part in the run were Mr. T. C. King, the Hon. Charles Douglas, Mr. Orson Wright, Mr. J. F. Johnson, Mr. Harding, Mr. E. S. Harding, Mr. and Mrs. Victor Oliver, Miss Evans, Mr. Earp, Mrs. and Miss Peberdy, Mr. R. E. Parker, Mr. F. O. Robinson, Mr. and Mrs. Barron, Master M. Barron, Miss Talbot, Mr. Doran, Dr. McAllister-Hewlings, Mr. J. McAlpin, Mr. Perkins, Mr. Gilbert, Mrs. Wherry, Mr. H. V. Oliver, Mr. and Mrs. Whilby, Mr. E. H. Herbert, Mr. Clerk, Mr. Thomas, Mr. Binns, Mr. S. Longmore, Mr. Thompson, Mr. Harris, Mr. Gerard, Mr. L. Pierpoint, Mr. Haynes, and Mr. A. McAlpin (hon. secretary).

MIDLAND.



ABOUT forty members and friends of the Midland A.C. visited the residence of Mr. J. Broughton Dugdale, at Wroxall Abbey, Warwickshire, last Saturday. Tea was partaken of at 5 o'clock, after which most of the members strolled round the grounds, gardens, and other places of interest. Mr. Dugdale personally conducted a small party over his private engineering shop, which is fitted on up-to-date lines and in which he takes a keen interest. The old abbey, park and grounds ranks as one of the finest places in the kingdom.

HEREFORDSHIRE.

THE roads were in such a bad state on May 10th, owing to the rain, that the Herefordshire A.C. decided to postpone the hill-climbing contest for motor-cycles until June 21st, when it will be held at 3 p.m., on Dinmore Hill. The Club, however, ran to the hill, and eight motor-bicyclists essayed the climb. Several accidents were narrowly avoided, but Mr. A. W. Marriott was not fortunate enough to save himself from a bad spill off his Griffon, as it was rounding the curve near the top. He luckily was only slightly bruised. The Club fixtures for June 4th, July 2nd, August 6th, and September 3rd are cancelled; but the Club will run to Sufton Court on July 12th to lunch with their president, Mr. J. T. Hereford.

SOUTH LINCOLNSHIRE.

A VERY successful meet of the South Lincolnshire Motor Club was held at Market Deeping on Saturday, and a good number of cars assembled in the Market Place. The members and friends were kindly entertained by Mr. and Mrs. G. Linnell to a sumptuous tea in the Town Hall, and the building was prettily decorated, and a splendid spread was provided. The following cars and cycles were present, namely:—Mr. Alfred Smith, Thrapston, 7½-h.p. Wolseley; Mr. Arthur Green, Spalding, Baby Peugeot; Captain Strangways, Deeping St. James, 3½-h.p. Enfield Quad; Dr. Husband, Crowland, 8-h.p. Wolseley; Rev. F. Taylor, Boston, 4½-h.p. Benz; Mr. Mayes, Bourne, 6½-h.p. Humberette; Dr. and Mrs. Miller, Wrangle, Baby Peugeot; Mr. F. Richardson, Sibsey, 10-h.p. Wolseley; Mr. T. O. Mawby, Spalding, 3-h.p. motor-cycle; Dr. Croxford, Peterborough, Humberette; Mr. W. White, Spalding, Bradbury motor-cycle; Mr. H. White, Spalding, Centaur motor-cycle; Dr. A. J. Stiles, Spalding, Excelsior motor-cycle; Rev. S. W. Skene, Deeping St. James' 2½-h.p. Vinco cycle; Mr. G. Linnell, Market Deeping, 10-h.p. Wolseley; Dr. Stanton, Deeping, 1½-h.p. Royal George; Mr. Carter, 1½-h.p. Royal George; Dr. and Mrs. Crompton, Benington, Baby Peugeot; Dr. Wrinch, Boston, Phœnix motor-cycle, and others. The weather

The Meet of the Hertfordshire Automobile Club at Dinmore Hill.
Photo by [*Mr. Quintin Miller.*

was fine, the affair was well organised, and the courtesy and kindness of Mr. and Mrs. Linnell added greatly to the pleasure of the gathering.

The next meet of the club will take place on Whit Monday, the destination being Woodhall Spa.

BERKSHIRE.

FIELD MARSHAL EARL ROBERTS, V.C., K.P., etc., who resides at Ascot, has accepted the invitation of the committee to become the hon.

Digitized by Google

president of the Berkshire Automobile Club. The fixtures for the remainder of the season are as follows:—June 8th.—At Ockwells Manor, Maidenhead, by invitation of Mr. E. A. Barry. June 25th.—At Beenham Grange, Beenham, by invitation of the hon. sec., Lt.-Col. W. Waring. July 13th.—At Holme Park, Sonning, Reading, by invitation of Capt. E. F. Rhodes. July 30th.—At St. Ann's Hill, Chertsey, by invitation of Mr. J. F. Ochs. September 14th.—At Inglewood House, Hungerford, by invitation of Mr. H. J. Walmesley.

IRISH MOTOR-CYCLE UNION.

A VERY enjoyable afternoon's sport was provided by the speed trials of the Irish Motor-Cycle Union on Saturday, when the motor-bicycle competitions under their auspices took place on the Velvet Strand at Portmarnock. The beach at Portmarnock, running along by the residence of Mr. John Jameson and the links of the Portmarnock Golf Club, is an ideal place for such a competition, as there is a perfect stretch of about a mile, and a less perfect one of twice that distance. The Irish Automobile Club may have to go there to hold its speed trials in August, as the authorities are reluctant to again allow permission to race in the Phœnix Park. There were three classes on Saturday, viz., machines under 120 pounds, machines under 150 pounds, and machines of unlimited weight. The races were run over a distance of a mile from a standing start, and the times given below, the fastest being equal to 35·29 miles per hour, speak eloquently for the suitability of the beach for motor racing, for, it must be remembered, the machines were ordinary roadster bicycles fitted with guards, brakes, silencers, etc., and roadster tyres, and the races were run against a fairly strong wind.

Class A, under 120 lbs., First Heat, J. C. Drury, Dublin, Triumph, 66 by 70, 1; Rev. W. Ireton, Belfast, Riley, 2; time 1 min. 52 4-5 secs. Second heat, W. B. Martin, Dublin, F.N., 64 by 72, 1; L. P. Oswald Sealy, Dublin, Brown, 2; time 1 min. 49 secs. Final, Martin, 1; Drury, 2; time of winner, 53 secs.

Class B. (under 150 lbs.), C. B. Franklin, F.N., 70 by 80, 1; R. W. Stevens, Phœnix (2); time, 1 min. 42 sec.

Class C. (unlimited as to weight) Final: C. B. Franklin, 1; R. W. Ireton, 2. Time 1 min. 45 sec.

ACTION OVER A MOTOR-CAR.

A SHERIFF'S Court was held at the Leeds Town Hall last week, when the Under-Sheriff of Yorkshire (Mr. Edwin Gray) and a jury were occupied with the assessing of damages in an action brought by Mr. Francis Sowden, of Ferncliffe, Clayton, against the Central Auto-Car Agency, Tottenham Court Road, London, for breach of contract in reference to the sale of a motor-car. Mr. Harold Newell, who appeared for the plaintiff, stated that the plaintiff was owner of a 9-h.p. Clement car, which he wished to dispose of for a more powerful car. He entered into negotiations with the defendants, who agreed to supply him with a 12-h.p. Sunbeam car for £510, of which he was to pay £255 in cash, the balance being represented by the Clement car, which was to be taken in part payment. Subsequently the Clement car was fetched by the defendants' representative, but the Sunbeam car was not sent as agreed to. Plaintiff made application for it but unsuccessfully, and eventually he had to buy another car, which cost him £476 13s. The plaintiff lost, therefore, the sum of £220 13s., and this was the amount which he claimed as damages. Evidence having been given as to the negotiations and agreements, the jury awarded the plaintiff the damages which he claimed.

UNLICENSED MOTOR-CAR.

AT Birkenhead County Magistrates' Court, Mr. Carlton Thompson was summoned for neglecting to take out a licence for his motor-car. Defendant admitted the offence but pleaded that he had applied for a licence some hours before the police stopped him, but did not receive it for four days. The Chairman said they would dismiss the case on payment of costs.

CASES DISMISSED.

AT Dewsbury two charges against motorists have been dismissed. Mr. Claude Jubb (Batley) was charged with driving his vehicle to the danger of the public, and Mrs. Martha J. Tolson with neglecting to use her "hooter," in consequence of which, it was alleged, a factory operative named Annie Ledgard was knocked down and injured. Both charges were denied and the defences sustained.

THE Hon. Claude Hay, M.P., appeared at the City Summons Court, on Tuesday, to answer a summons for interrupting the free passage of pedestrians in St. Paul's Churchyard. Mr. Hay, it was alleged, drove his motor-car on the wrong side of the "island" in leaving the churchyard for Cheapside, with the result that several people had narrow escapes from being run over. The magistrate dismissed the summons, remarking that had it been for driving on the wrong side of the road there would have been a conviction.

AT Christchurch, Charles Pooss, of the Triangle, Bournemouth, was summoned for having driven a motor-car in a reckless manner and to the danger of the public through the borough of Christchurch on April 1st.—At a former Court it was alleged that P.C. Boyd had, on the occasion of serving a previous summons, said to Mr. Pooss, "I will have you again soon." Supt. Payne thereupon applied for an adjournment to enable him to call evidence to disprove that statement, and P.C. Sumner was now called. He stated that he was in company with P.C. Boyd when a summons was served upon the defendant in respect to a charge of having driven a motor-car furiously. To the best of his recollection the following conversation took place. P.C. Boyd said, "I have got a summons for you, Mr. Pooss." Pooss said, "You are very smart," and Boyd retorted, "Yes, we are paid to be smart." For the defence, Mr. Bone urged the Bench to dismiss the case, pointing out that they were asked, on the evidence of a police officer which was totally uncorroborated, and in a case in which corroboration could have been brought, to convict a motor-car driver of a serious offence. The Bench dismissed the case, but they desired to say, said the Chairman, that the constable had acted thoroughly honestly and openly in the matter.

MOTORISTS v. HORSE DRIVERS.

AT Hailsham, Philip Luck, jun., was summoned for leaving a horse and cart unattended in Willingdon. Mr. J. B. Campion Coles was the prosecutor. He deposed that he and his son were driving through Willingdon Street on a motor-car. Defendant's cart was standing at a narrow part of the road, unattended, and as Mr. Coles stopped his car to allow another car coming in the opposite direction to pass, defendant's horse swerved out into the road and nearly caused a serious accident. A man ran up "from behind somewhere" and took charge of the horse, but for quite five minutes the horse was left unattended. The wheel of the van was chained. Mr. J. J. Hissey, Trewin Towers, Eastbourne, the driver of the other motor-car, stated that he was driving through Willingdon, and going very slowly, when the horse suddenly swerved right across his path. As far as he could see the cart was quite unattended. Mr. Luck, in defence, said his horse was a very quiet one, and the car ran into it and dragged it round. The wheel was chained, and the animal was fastened by the head. The Bench fined defendant £1 and 7s. costs, or fourteen days in default.

AT Horncastle, Tom Fenson and Jesse Brown, waggoners, were charged with neglecting to pull to the left side of the road and so allow the free passage of a motor-car, belonging to Dr. E. B. Reckitt, of Boston, at Tattershall, on the 13th April. The evidence of Dr. Reckitt and his driver was to the effect that the defendants took no notice whatever of the motor-horn. Two of them tried to get out of the way, but the third made no attempt to do so, and the car collided with a gravel heap and was smashed. The magistrates expressed their opinion that the defendants had no time to get out of the way, and there was no evidence that they refused to do so when called upon. The case was dismissed.

CONVICTIONS AGAINST MOTORISTS.

Place.	Summoned for	Fine.
West Ham	Failing to produce licence	£2, etc.*
,, ...	Driving without licence	£2.
Marlboro' Street, London, W.	Reckless driving	£20 or 3 months.

Southport	,, ,,	£2.
London, Marlborough Street		
Lambeth	,, ,,	£10.
	Refusing to stop when accident occurred	£10, etc.

* Licence endorsed in addition to fine.

POLICE TRAP.

THE Andover County Bench had a batch of motorists before them the other day on charges of driving at a speed dangerous to the public. The offences all occurred on the Andover to Salisbury main road, at a point where it passes through the village of Nether Wallop, and where there are cross-roads leading from the direction of Grateley to Broughton. A number of motorists have already been trapped there by the police.

THE

Motor-Car Journal

VOL. VI.] LONDON, SATURDAY, MAY 28, 1904. [No. 273.

Published Weekly by CORDINGLEY & CO., 39 & 40, Shoe Lane, London, E.C.

COMMENTS.

THE Motor Union has just been successful in obtaining the first High Court decision in favour of motorists, in connection with criminal proceedings, that has been given since the passing of the Act of 1896. The case, which came before the Court of King's Bench, composed of the Lord Chief Justice, Mr. Justice Wills and Mr. Justice Kennedy, was that in which Mr. Clifford, jun., of Loughborough, had been granted a *nil nisi* which obtained against the Loughborough justices for a *certiorari* to quash a conviction by the applicant by them under Section 1 of the Motor Car Act. The conviction was worded as follows:—"That on a public highway there situate he drove a motor-car at a speed or in a manner which was dangerous to the public, having regard to all the circumstances of the case, including the nature, condition, and use of the highway, and to the amount of traffic which actually was at the time or which could reasonably be expected to be on the highway." The summons to appear before the magistrates was worded in the same way, and the rule was obtained on the ground that the conviction was bad for duplicity as charging more than one distinct offence on a single summons.

◆ ◆ ◆

Success of the Motor Union.

As already announced in these columns the Lord Chief Justice gave judgment for the motorist. He said it was impossible to contend that the only offence mentioned in the section was that of driving at a speed dangerous to the public, for it was obvious that there was also the offence of driving in a manner dangerous to the public. The magistrates, therefore, had not to consider the two things together but ought to have considered whether the defendant was driving in a manner dangerous to the public apart from the question of speed. The conviction therefore could not stand. Mr. Justice Wills and Mr. Justice Kennedy having given judgment to the same effect the rule was accordingly made absolute and the conviction quashed.

◆ ◆ ◆

The British Team.

THE Races Committee of the Automobile Club have issued a communication in which they say that the statement appended to the Races Committee's award, viz., "But for the mishap to the car No. 6 driven by Mr. Clifford Earp it would have taken second place in the team selected," was published with the award as a recognition of the previous performances of this car and its driver during the trials. There was nothing in the statement to warrant the assumption which has been made that there was any wide difference between the performances of car No. 6 driven by Mr. Earp and car No. 12 driven by Mr. Jarrott. After the conclusion of the trial on Thursday the committee had to decide which of the cars and drivers then before them were best suited to represent the Club in the race. The committee throughout had regarded the driver and the car as a unit, which could not be separated after the selection trials. They therefore formed their judgment on the results of the trials and the condition of the cars and drivers on the Thursday evening, and did not feel justified in entering into speculation as to what might be their condition at a subsequent date.

◆ ◆ ◆

Railways and Motor-Cars.

AMONG railways the Great Eastern Company has always shown an enterprising spirit, and it is freely rumoured along its system that, should the motor-car service recently inaugurated between Southwold and Lowestoft be successful, another service will be run at Clacton-on-Sea. This is a popular resort, and although the country round about is somewhat dreary, there are a few pleasant drives—one to Walton and another to St. Osyth, in which latter direction, it is thought, a motor-car service is likely to be started. It should pay and prosper.

◆ ◆ ◆

The Burton Meet.

THE Manchester Automobile Club, which is organising the united club run to Buxton, has now definitely fixed the date for Saturday, the 11th prox. It is to behoped that the gathering at the Empire Hotel there will be a fully representative one so far as northern motorists are concerned. Already most of the leading clubmen have promised to attend, and the collection of cars that will assemble in the pleasant Derbyshire resort will be fully representative of all the leading types, thus giving an added interest to the event.

◆ ◆ ◆

S.I.

SOME correspondence has reached us with regard to the Identification Mark S.I. which has been seen about London of late. So many readers appear to have seen this number and to have noticed its omission from our Identification Card that it may be of interest to recall the passage in the Circular of the Local Government Board to county councils issued in November last, according to which "it has been arranged that no use shall be made by English and Welsh registering authorities of the letters G., I., S., V., or Z, the letters G., S. and V. being intended to be distinctive of Scottish, and the letters I. and Z. of Irish authorities." The two letters S.I. cannot therefore properly occur in the same index mark.

◆ ◆ ◆

Trial for Small Cars.

THE question of a trial for small cars for 1904 has been further considered by the expert and technical committee of the Automobile Club, and the secretary has been instructed to insert a rule in the classification clause which would exclude quadricycles and similar machines from taking part in the Trials. The classification will be as follows:—Class 1—Not exceeding £125; Class 2—Exceeding £125 and not exceeding £150; Class 3—Exceeding £150 and not exceeding £175; Class 4—Exceeding £175 and not exceeding £200. Entries will only be accepted from manufacturers or their nominees. No manufacturer will be allowed to enter more than two cars, which, unless there is more than twenty per cent. difference in cylinder capacity, shall then be run as a team. Certificates will only be awarded to those cars which actually receive a

Digitized by Google

prize, but it is left to the discretion of the judges to award an "honourable mention" to those cars which they may think worthy of it. The fundamental feature of the trials will be non-stop runs, and these should consist of, say, six non-stop runs of 100 miles each, or twelve non-stop runs of 50 miles each, to be carried out in six days, and these runs should be performed at a minimum average speed of twelve miles an hour for all except in Class 1, in which the average speed might be ten miles an hour

Dr. Fitzgerald, of Grahamstown, South Africa, crossing a river.

◆ ◆ ◆

Motoring in South Africa.

One of the South African readers of the *Journal*, Dr. Fitzgerald, of Grahamstown, has sent us two interesting photographs, which we reproduce herewith. The doctor writes that "the photographs were taken on a trip that I and three friends took the other day down Belmont Valley on my 10-h.p. Star car. We went about fourteen miles, and in the course of the trip we crossed the Kowrie River near its source seven times. Some of the gradients were 1 in 4 and 1 in 5, on which we never shed our passengers once. One picture shows the first drift across the Kowrie River, and the other a group of Kaffirs round the Star. The trip was done without any trouble, and throughout the whole fourteen miles we were unable to even put in the top speed, as the roads are fiendish, the surface bad, and never level."

◆ ◆ ◆

Motor Maintenance.

Mr. E. Shriver Reese, president of the Automobile Club of Cleveland, U.S.A., than whom there is no more enthusiastic motorist, says:—"The expense of operating a motor-car is of little consequence in proportion to mileage. I have never heard anyone make complaint on this score. The expense of maintenance and repair depends largely on the driver and the care of the vehicle. A careful driver who owns a good machine, and takes proper care of it, will have no cause for grievance as to repairs. The popular idea as to the cost for necessary repairs being excessive is largely due to the conditions that formerly existed, when many of us, who were among the early purchasers, were practically trying out the experimental work and designs of the manufacturers. This condition no longer exists. Any of the prominent cars now on the market can be relied upon for substantial and satisfactory service, according to their type. There will, of course, continue to be improvements, but the inducement to an owner to make a change in the future will be because the improvements are desirable and not because they are necessary. The cost of maintenance for my three cars during 1903 was £62, including tyre renewals and the general overhauling of one of the older vehicles. If only half the care is given to a good motor-car that is usually given to a good horse, an intending purchaser need not, in these days, feel deterred by any idea that the expense of maintenance would be excessive or unreasonable."

◆ ◆ ◆

Motors for Ministers.

It appears, from an article in the "Christian World," that the complaint of "Mondayishness"—a common failing with ministers—can be greatly relieved by motoring. A parson who has become a very ardent motor-cyclist writes enthusiastically of the joys of whirling through space at the rate of many miles an hour, and has even ventured to give his clerical brethren some good technical advice. There is no doubt that a short spin on any form of automobile is a capital awakener of the nerves of men, and that ministers as well as doctors will find health of body as well as economy of time in the use of the motor.

◆ ◆ ◆

Children and Cars.

During the Glasgow to London run of the Scottish Club last week, much interest was shown in the automobiles by small children along the line of route. Nearly all appeared to have paper and pencil, and to be recording the numbers of the cars. Curiously enough, we have since received an envelope enclosing lists of scores of motor-car identification marks.

◆ ◆ ◆

Dr. Fitzgerald visiting the Kaffirs on his 10-h.p. Star car.

◆ ◆ ◆

[Motor-Car Regulations in the Transvaal.

The Transvaal Government have recently approved by-laws which not only regulate purely road traffic, but enforce certain requirements as to the construction of motor-cars. They must, for instance, be mounted on adequate springs; unless motor-cycles, they must be capable of being worked both forwards and backwards; they must be provided with at least two independent brakes. Cars must not exceed 6½ feet in width. Should petroleum or other inflammable liquid

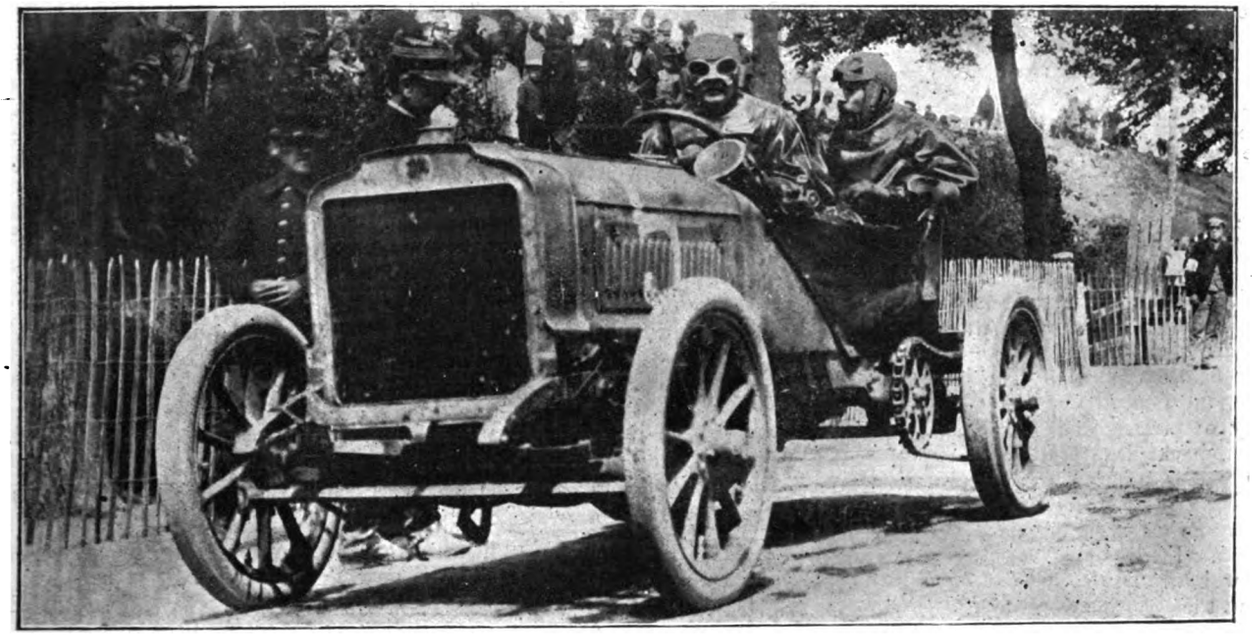
Digitized by Google

be used to produce power for a motor, such inflammable liquid must be kept in vessels containing not more than twenty gallons each, and no vehicle is to be allowed to carry more than two.

◆ ◆ ◆

Traders' Marks.] TRADERS must exercise considerable care with reference to their identification marks, and not allow them to be indiscriminately used by anybody, or even to be allowed on cars which are likely to be taken out without permission by their employees. As a general rule it may be taken for certain that most of the inconsiderate driving of which complaint is made is by men who are using cars which do not belong to them. Another point as to which traders should exercise much discretion is as to making a record of cars out on trial. Two cases have just been heard where neglect to do this immediately the car was sent out has been followed by fines.

◆ ◆ ◆



Hampshire and the Act. THE special Committee of the Hants County Council as to the Motor Car Act, 1903, submitted a report in which they stated that 116 parishes had applied for the erection of about 350 sign-posts denoting dangerous corners, cross-roads, and precipitous places, and the committee recommended that a sum of £100 should be provided by the Council for the purpose of any cases which, in the opinion of the county surveyor, were urgent. Up to the 1st May the number of motor cars registered in the county was 616, and 873 licences had been issued to drivers. Mr. E. P. King caused some amusement by moving as an amendment that no sign-post be erected except on the recommendation of a coroner's jury. The amendment, however, found no seconder, and the recommendation was agreed to.

◆ ◆ ◆

Automobilism in South Wales. THE committee of the South Wales and Monmouthshire Automobile Club, in their annual report, state that they have been successful in inducing Mr. S. Andrews to reduce the toll on motor-cars passing through the gates on the Penarth road from 1s. to 6d. The state of the roads in various parts of South Wales has received much attention from the committee. The consideration given to the matter by the Glamorgan County Council had been much appreciated, and it was hoped to receive similar assistance from the Breconshire Council. The committee ask for reports from members who experience inconsiderate treatment on the road, desiring to make an example of some of the persons who display prejudice against motor-cars. The committee regret that they have not yet been successful in finding premises in Cardiff suitable for a club garage. The accounts show a balance in hand of £58.

◆ ◆ ◆

In New Zealand. A MEETING of the Automobile Association of New Zealand was recently held at Canterbury, Mr. J. S. Atkinson being in the chair. With reference to the efforts of the Association to have the Waipara Bridge planked, in order that it should be available for automobile traffic, letters were received from the League of New Zealand Wheelmen, the Canterbury Centre of the League, and the Christchurch Cycling and Motor Club, promising co-operation. In response to a letter from the secretary asking the Mayor what were his ideas in regard to opening up Hagley Park for automobilists the following letter was received from the Town Clerk:—"In compliance with your request, I am directed by his Worship the Mayor to inform you that, personally, he feels that carriage traffic should not be allowed in the Park, and considers that if automobiles were permitted to enter the Park, it would encourage those persons, if any, who wish to open it to ordinary traffic." A committee was appointed to deal further with the subject and also to arrange for the appointment of a paid secretary. Evidently the organisation of the automobile movement in the Colonies is proceeding rapidly.

Thery—the Winner of the Race—on his Georges Richard-Brasier Car.

◆ ◆ ◆

The Agitation for Alcohol. LIEUTENANT W. G. WINDHAM has been lecturing under the auspices of the Junior Institution of Engineers, at the Westminster Palace Hotel, on the "Running of Motor-cars and Cycles," in the course of which he laid stress upon the undeniable usefulness of the motor, and remarked that in the development of reliability and perfection serious considerations are the continuation of the supply of rubber and petrol, or of an adequate substitute for them. He impressed upon his audience the importance of every attention and encouragement being given to the motor-car industry, and in this respect he thought our Government might well take a lesson from our neighbours in France. The French Government is doing everything

Digitized by Google

possible to enrich their country by the sale and use of the motor-car and to produce home-grown alcohol for industrial purposes. Only 2 per cent. of the world's output of petroleum is suitable for the distillation of motor spirit. "This means," said the lecturer, "that at any moment the petrol output might be cornered or the supply might run short." Last year, for instance, at the time of the military manœuvres, when only a few hundred gallons of motor spirit were ordered, the price went up 50 per cent., and in some places petrol could not be had at all. "Why," asked Lieutenant Windham, "should we be at the mercy of other countries when we can ourselves well grow what is required for the production of alcohol and render ourselves independent of the foreign oil supply?"

◆ ◆ ◆

The French Eliminating Trials.

THE result of the great race in the Ardennes last week has occasioned the greatest surprise in French motoring circles. Rigolly and his Gobron-Brillie were the first favourites before the race, and it was fully expected that Panhards would be well to the front with at least one vehicle. The Mors Company have of course competed in the Gordon Bennett Race before, but the Georges Richard-Brasier and Turcat-Mery cars will make their *debut* in the great international event at Germany next month. It is noteworthy that the successful vehicles are all of the chain-driven type.

◆ ◆ ◆

Mr. Jarrott's Views of the Race.

AS we go to press we have received a letter from Mr. Jarrott, from which we take the following:—"You will probably have observed from the results of the French Eliminating Trials that one of the two cars entered by Messrs. Turcat-Mery, the designers of the De Dietrich cars, gained third place in the French team, and that the fourth place and first reserve was gained on a De Dietrich driven by Gabriel. The Turcat-Mery and the De Dietrich cars are identical in every respect; the Turcat-Merys were finished two or three weeks ago and thus were probably tried before the race. The De Dietrich's were, on the other hand, only finished the week before, and there was no opportunity of proper trials being made, so that the success of Gabriel is remarkable. The latter would probably have been in a much better position were it not for the fact of his water tank breaking and delaying him considerably. My own trouble was in the same direction, my water tank giving way after the second round. In the endeavour to keep everything down to the prescribed weight the tanks were made somewhat lighter than was safe and the performances of the cars suffered accordingly."

◆ ◆ ◆

Easter in Australia.

THE most ambitious motor tour yet attempted in Australia was concluded when the Automobile Club of Victoria returned to Melbourne after its Easter trip through the western district of Victoria. The trip practically started from Geelong on the Friday, though the majority of the tourists left the club rooms on Thursday afternoon. Those who had cars drove to Geelong, and those mounted on motor-bicycles mostly went across by boat. However they went, and all the tourists, to the number of forty-one, foregathered in Geelong on Thursday night. The vehicles included two Decauvilles, six Humberettes, two De Dions and an Argyll. The first night of the tour proper was spent at Camperdown, and on Saturday morning, at 9.30, the journey was resumed, and all that day the tourists swept on under idyllic conditions. Hamilton was reached by dusk, and the motorists were entertained at a social given in their honour by the Mayor of the town. An early start was made from Hamilton on Sunday morning, for the longest day's journey of the tour had to be faced, a run of 120 miles to Ballarat. The last stage of the trip lay between Ballarat and Melbourne, a distance of sixty-eight miles. Ballarat was left at 10.45 a.m., and, after a glorious run over the Pentland Ranges, Ballan and refreshments were reached. Then, with stoppages at Bacchus Marsh and Keilor, the journey to Melbourne was resumed, and at 6.30 that evening the club-rooms were reached. There the tourists felicitated themselves. Most of the trouble on the road was caused through the water tanks and radiators on the light machines leaking, whilst on the heavy machines there were tyre troubles to be encountered. In neither the light nor the heavy cars, however, did the mechanism give the slightest trouble. Petrol depots were established along the road by Mr. H. James. At Geelong the party took along forty gallons of petrol, sixty at Camperdown, eighty at Hamilton, and sixty at Ballarat, and this took them comfortably back to Melbourne.

◆ ◆ ◆

Guides.

MR. T. THROUP, of Bradford, has brought out a new edition of his motorists' guide to the North of England, and also a companion volume entitled the "North Wales Cyclists' and Motorists' Guide." Both are well illustrated, while each contains a selection of routes admirably devised for the saving of time and temper of those who travel quickly by road. There are many charming districts in both parts of Britain made accessible by the advent of the motor-car, and to these Mr. Throup's books are capital companions.

◆ ◆ ◆

Hill Climbs.

THERE will be a plethora of hill-climbing competitions this season, and already the A.C.G.B.I. have approved of such contests being organised by the West Surrey, the Midland, the Lincolnshire and the Derby automobile clubs, on condition that the consent of the local authorities should be obtained and no inconvenience caused to the public. These events naturally arouse considerable interest in the districts in which they are held and do much to maintain the enthusiasm of members in their respective clubs.

MR. BALFOUR crossed from Dover to Calais on Monday for a motor tour in France.

AN automobile club has been formed at Stockton, with Mr. Leonard Ropner, J.P., as chairman.

MR. D. T. CALLOW, of Castletown, Isle of Man, has become a motorist since the Eliminating Trial in that island.

THE directors of the Car and General Insurance Corporation, Limited, have now extended their policies to cover the owner and the paid driver against accidental injury sustained when examining or standing by the insured car.

THE Committee of the Royal Horse Show have made arrangements for motor-cars to be admitted to the show ground on the occasion of their annual show to be held in the Old Deer Park, Richmond, on the 10th and 11th prox., at a charge of 10s. each car and 1s. each occupant. An enclosure will be reserved for motor-cars.

THE 12-h.p. Richardson car in the Glasgow-London run went from the works at Saxilby to Glasgow, starting at 4 a.m. on the 15th inst., and reaching Glasgow at 6.45 p.m., without any punctures or any stops for meals. The sole stops were two to buy petrol and once to speak to Mr. Belcher on his 8½-h.p Humber. The last 112 miles was absolutely non-stop.

COLONEL W. J. BOSWORTH'S latest acquisition is a 14-h.p. Clement car. After exhaustive trials he has come to the conclusion that light cars of this type are the most suitable for his special work, namely, the instruction of officers in field sketching and reconnaissance. As an instance of the value of motor-cars for this particular kind of military work, it may be mentioned that recently a party of officers, leaving Cedar Court, Roehampton, in three cars, had a run of fifteen miles, sketched three square miles of country, and returned to Roehampton, the time occupied from start to finish being just over three hours.

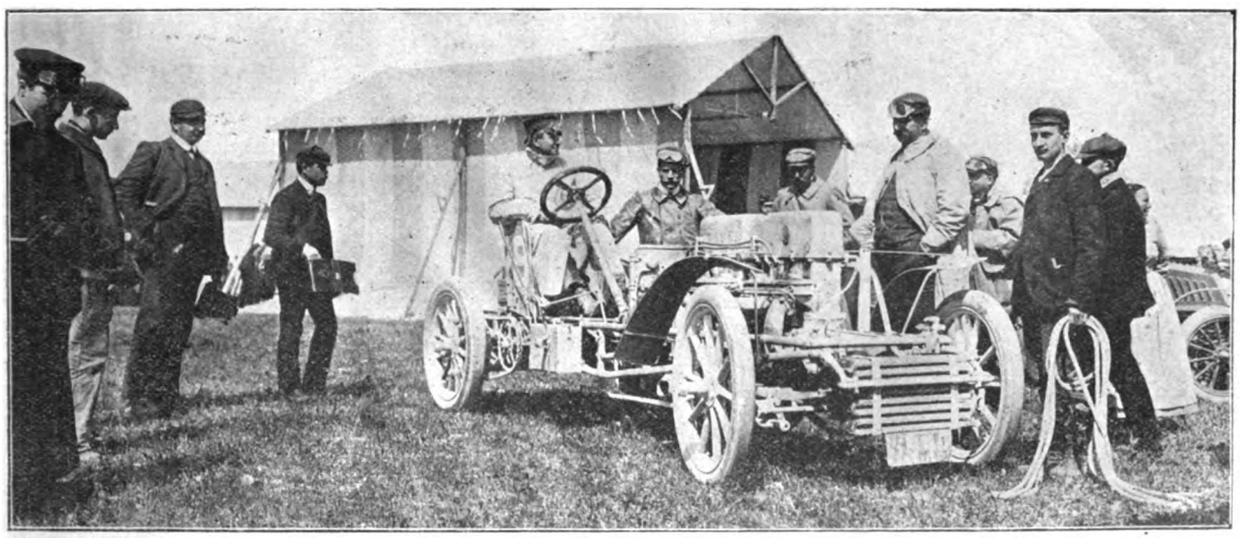
Digitized by Google

The French Gordon Bennett Eliminating Trials.

PREPARING FOR THE EVENT.

MAZAGRAN, Thursday, May 19.

ONLY a few hours separate us from the start of the great event of the French motor-racing season—the Eliminating Trials for the team of three cars and drivers to represent France in the Gordon Bennett race in Germany next month. The course for the contest is entirely in the Department of the Ardennes, and passes through one of the most sparsely populated parts of France. Mazagran, where the start is to take place, will be vainly sought even on ordnance survey maps, as it consists in normal times of one farm and one *estaminet* at the crossing of the roads from Chalons to Meziéres and from Rethel to Vouziers. The two last-named places are the only towns of any importance on the route. To-day Mazagran is temporarily turned into a small town, bustling with active officials and noisy with the sound of the exhaust of the racing cars already on the scene. The circuit, originally some twenty-five miles longer, has, in order to steer clear of a cluster of villages, been reduced to fifty-eight miles. Over this distance three miles and one-sixth will be "neutralised," where the road passes through Rethel and Vouziers and two villages, Le Chesne and Novy, the total time allowed for travelling over these portions of the circuit being 26 min. The net length of the course is thus reduced to 54 5–6 miles. In order to cover a distance nearly equivalent to the minimum required for the Gordon Bennett Cup, the cars will have to travel six times round the circuit. The total distance will, therefore, be 348 miles gross and 329 miles net. The test differs materially from that of the British cars in the Isle of Man, the French Club relying on a contest affording as far as possible a duplicate of the conditions of the actual race. Paris has almost emptied itself of motorists, special and excursion trains bringing thousands to Attigny, Vouziers, Rethel, and other places on the course. The hotels and inns for twenty miles round Mazagran are crowded, and many visitors have been compelled to seek quarters in farms, while others are arranging to camp out in the open air. All imaginable precautions have been taken to prevent accidents to spectators. The road in all the villages has been fenced off, and will be kept all along by troops. No one except the timekeepers will be allowed on the course. The road has been sprinkled with Westrumite to lay the dust. At each of the neutralisations a corps of twenty-five military cyclists will be at the disposal of the timekeepers in piloting the cars, while a small special train is being kept in readiness at Attigny to convey the injured to the hospital at Rheims in case of accident.



Thery—the Winner of the Race.

The weighing-in took place to-day, and, strange to relate, there was not a single forfeiture, the whole of the twenty-nine cars putting in an appearance. An extra 7 kilogs. over the 1,000 kilogs. was allowed for the cars having magneto ignition. After being scaled, attention was centred by the authorities on the condition of the brakes.

THE RACE.

MAZAGRAN, Friday, May 20.

There was little rest for anyone last night. Ere the cocks began to herald the dawn of the eventful day, all around the course there were signs of activity rarely if ever seen in this part of France. The soldiers gradually took up their positions, and at 4 a.m. the course was finally closed, except to the racing cars. Baron de Crawhez (No. 4, Hotchkiss), was the first to appear at the starting-point, where at ten minutes to five all the competitors were lined up for the great event. A few changes took place at the last moment in the order of starting, the correct one being indicated in the table on page 278, which also shows the weight of the cars, the type of inlet valve, the ignition, the wheel base, and the wheel gauge of the competing vehicles. There was not a single forfeit—all the twenty-nine cars left in their due order, punctually to the second, commencing with Baron de Forest on his De Dietrich at five a.m. The others were sent off at two-minute intervals, Burton (Gobron-Brillié) being the last to get away at 5.56 a.m. Among the sensations of the start was the wild jump given by Salleron's car, the other Mors racers going off with the same

Burton, on the Gobron-Brillie, at the Weighing-in.

alacrity. The Gobron-Brilliés were literally mere skeletons, displaying all their interior workings, one of the drivers, Duray, to be in harmony with his machine, going off gaily without the trace of a wrap. The Darracqs made a deafening noise at the start, which scared all the onlookers, even judges and officials.

News of the racers was now eagerly awaited. The wireless telegraphy installation worked very well at first, but broke down as the morning wore on. The first round knocked out Baras, (No. 2, Darracq) due to a broken wheel, Rigolly (No. 9, Gobron-Brillié) owing to a leaky radiator, A. Fournier (No. 14, Hotchkiss) and Hanriot (No. 13, Clement-Bayard). Fournier spilled over the level crossing at the bottom of a steep gradient at Saulce-Mondin, one of the dangerous points of the course. His car overturned completely, but both he and his mechanician escaped miraculously without a scratch. De la Touloubre (No. 20, Turcat-Mery), Baron de Crawhez (No. 4, Hotchkiss), and Guders (No. 23, Clement-Bayard), were also delayed on the first round. The cars which were going best at this early stage were No. 3, the Clement-Bayard, driven by Clement, Jun., No. 5, the Georges Richard-Brasier, driven by Thery, Salleron's Mors, H. Farman's Panhard and Rougier's Turcat-Mery. The times at which the various competitors completed the first round are shown below :—

The record-board at Mazagran, giving the hour of departure, the time of completing the circuit, and the speed over the last flying kilometre.

First Round.

10.	Rougier	6.46	29.	Burton	7.38
11.	Gabriel.....	6.48	22.	Wagner	7.39
15.	Caillois.....	6.56	28.	Tart	8.15
17.	Léger	7.5	20.	De la Touloubre ...	8.59
16.	Chanliaud	7.8	4.	De Crawhez	9.45
12.	Béconnais	7.10	23.	Guders	10.40
18.	Teste.....	7.15			

It was in the second round that Thery (No. 5, Georges Richard-Brasier) ran into first place, a position he retained to the end. Baron de Forest (No. 1, De Dietrich) fell back to the third place. Farman (No. 8, Panhard), gained slightly on Salleron (No. 7, Mors). Among those who gave up in the second circuit were Chanliaud (No. 16, Serpollet), owing to a broken front axle. Wagner (No. 22, Darracq), Guders (No. 23, Clement Bayard), Tart (No. 28, Panhard) and Burton (No. 29, Gobron-Brillié). The latter's stoppage was due to a leak in the water-jacket, causing water to get into the cylinder.

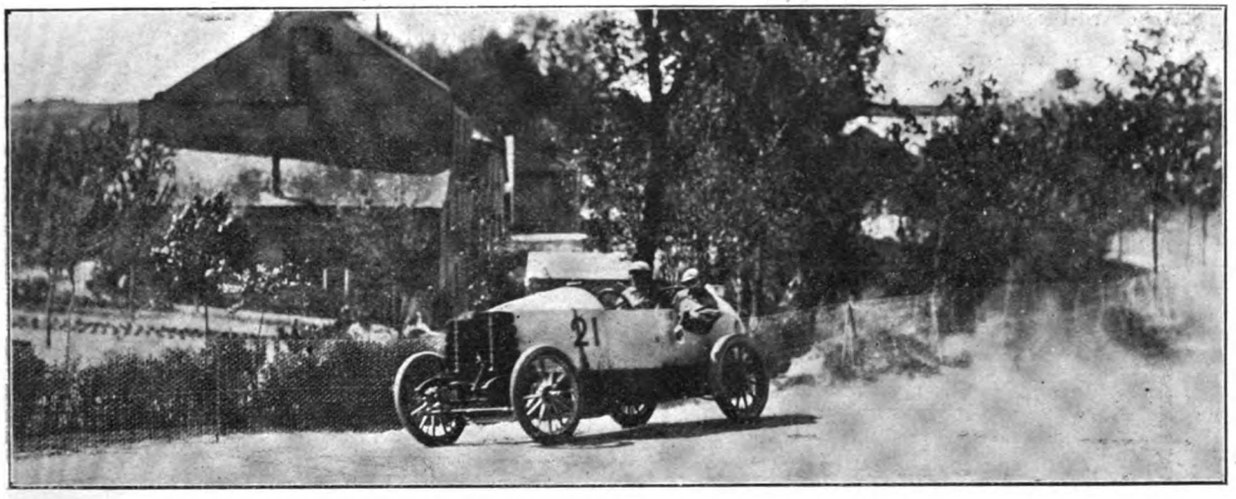
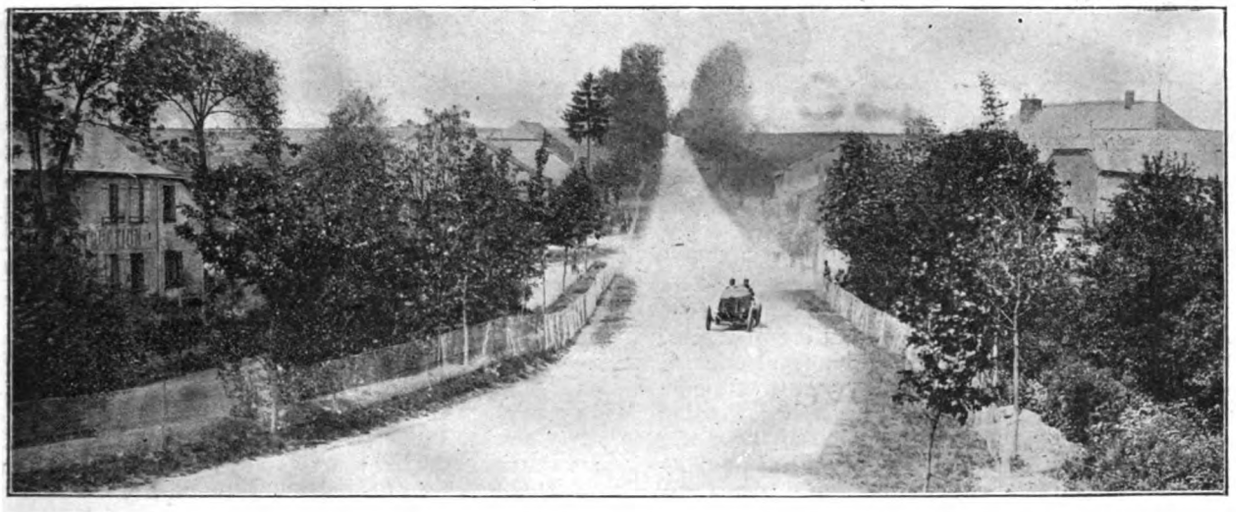
SECOND ROUND.



Order of Starting.	Driver.	a.m.
5.	Théry	7.50
3.	A. Clement	7.51
1.	De Forest	7.56
8.	Farman	7.57
7.	Salleron	8.2
11.	Gabriel	8.8
10.	Rougier	8.13
6.	Le Blon	8.19
17.	Léger	8.28
15.	Caillois	8.38
18.	Teste	8.47
21.	Jarrott	8.52
24.	Amblard	8.55
12.	Béconnais	9 0
25.	Stead	9 6
27.	Lavergne	9.6
26.	Pelzer	9.33
19.	Duray	10.13
20.	De la Touloubre	10.49
4.	De Crawhez	11.20

In the third round Farman, Gabriel and Salleron passed Clement, Jun., De Forest, too, falling further to the rear. Le Blon (No. 6, Serpollet) was going well, and had managed to retain his position. De la Touloubre (No. 2, Turcat-Mery) again experienced trouble, as also did Leger (No. 17, Mors), he occupying nearly six hours in completing the third circuit, in which Baron de Crawhez' Hotchkiss car, No. 4, was upset, the steering gear being damaged and the mechanician slightly injured in the head. In this round Duray, No. 19, also abandoned, putting the Gobron-Brillié entirely out of court. Lavergne (No. 26, Mors) also gave up.



THIRD ROUND.

Order of Starting.	Driver.	a.m.
5.	Théry	9.6
8.	Farman	9.21
11.	Gabriel	9.34
7.	Salleron	9.35
3.	Clément	9.39
10.	Rougier	9.40
1.	De Forest	9.45
6.	Le Blon	9.54
15.	Caillois	9.58
24.	Amblard	10.21
18.	Teste	10.25
21.	Jarrott	10.42
12.	Béconnais	10.6
25.	Stead	10.51
26.	Pelser	11.11
20	De la Touloubre	12.25
17.	Léger	2.15

The fourth circuit was a very disastrous one, only twelve out of the twenty-nine competitors finishing it. Théry still kept his lead, with Salleron close behind, the latter having got ahead of Gabriel and Farman. Clement, Jun., too, had a bad time, his fourth round occupying nearly three hours. Those who were forced to abandon in this circuit were:—De Forest (No. 1, De Dietrich), Beconnais (No. 12, Darracq), Leger (No. 17, Mors), De la Touloubre (No. 20, Turcat-Mery), and Amblard (No. 24, Hotchkiss). The worst accident of the day happened to the latter; the rear axle of his car broke while he was going at full speed in passing over a *caniveau*. The vehicle dashed into two tall poplars, turned a series of somersaults over a distance of 300 yards, and eventually smashed itself to pieces. Strangely enough, neither Amblard nor his mechanician were seriously injured. The latter's foot was broken and Amblard had several teeth knocked out and his face cut. Baron Henri de Rothschild's motor ambulance did good service, speed-

ing to scenes of accidents, but only one man, Amblard's mechanician, was sufficiently badly hurt to be obliged to use it.

FOURTH ROUND.

Order of Starting.	Driver.	a.m.	Order of Starting.	Driver.	a.m.
5.	Thery	10.32	15.	Caillois	11.30
7.	Salleron	10.59	18.	Teste	11.54
11.	Gabriel	11.9	21.	Jarrott	12.10
10.	Rougier	11.11	25.	Stead	12.20
8.	Farman	11.23	3.	Clement	12.26
6.	Le Blon	11.29	26.	Pelser	12.58

In the fifth circuit Thery and Salleron passed first and second, with Rougier (No. 10, Turcat-Mery) in the third place, owing to Gabriel (No. 11, De Dietrich), having to stop to make some repairs. Clement, Jun., did well in this round, getting back to eighth position, passing Teste, Jarrott, and Stead (No. 25, Georges Richard-Brasier), the latter giving up owing to a leaky tank.

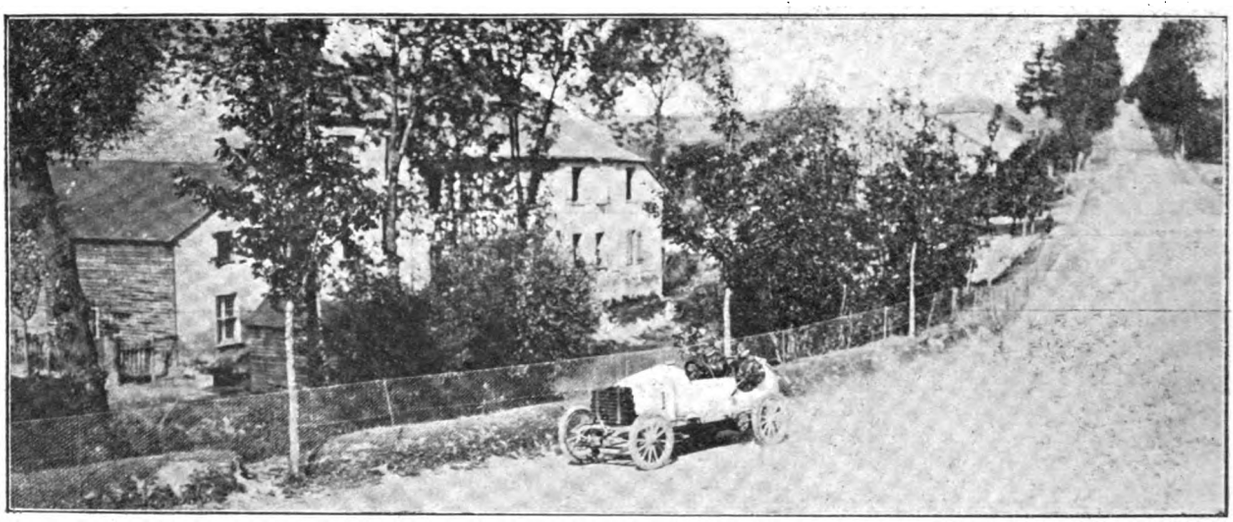
FIFTH ROUND.

Order of Starting.	Driver.	a.m.	Order of Starting.	Driver.	p.m.
5.	Thery	11.55	6.	Le Blon	1.8
		p.m.	15.	Caillois	1.16
7.	Salleron	12.28	3.	Clément	1.51
10.	Rougier	12.36	18.	Teste	2.4
11.	Gabriel	12.45	21.	Jarrott	2.14
8.	Farman	12.55	26.	Pelser	2.36

The last round of the race was entered upon about midday, and brought with it no change in the first four positions. Farman, however, fell back, owing to overheating troubles, from the fifth to the seventh position. Out of the twenty-nine starters only ten finished before 5 p.m. Although the "weeding out" was thus fairly heavy, it must not be forgotten that many of the competitors who had to stop for small repairs and adjustments gave up when they saw they had no chance to secure a place in the classification. The Panhard cars, which made a good impression, suffered seriously from overheating of the engine.

FINAL ROUND.

Order of Starting.	Driver.	p.m.	Order of Starting.	Driver.	p.m.
5.	Thery	1.22	15.	Caillois	2.56
7.	Salleron	1.56	8.	Farman	3.13
10.	Rougier	2.6	3.	Clement	3.24
11.	Gabriel	2.25	18.	Teste	3.35
6.	Le Blon	2.35	26.	Pelser	—



Some time elapsed ere the definite classification and net times of those who finished was announced. The figures given out by the Sporting Commission of the A.C.F. are shown below:—

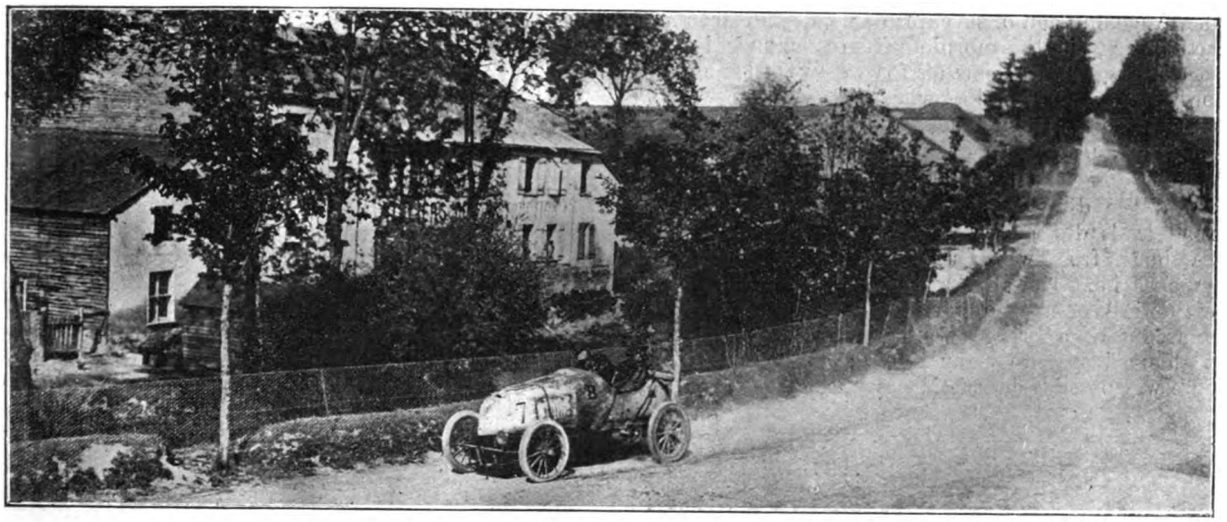
		H.	M.	S.
1.	THERY (Georges Richard-Brasier)	5	20	28
2.	SALLERON (Mors)	5	40	2
3.	ROUGIER (Turcat-Mery)	5	45	5 2-5
4.	GABRIEL (De Dietrich)	5	48	5 4-5
5.	LE BLON (Serpollet)	6	13	32
6.	CAILLOIS (Georges Richard-Brasier)	6	21	27 1-5
7.	TESTE (Panhard)	6	40	23 4-5
8.	H. FARMAN (Panhard)	6	51	0
9.	PELSER (Serpollet)	7	0	27 3-5
10.	A. CLEMENT (Clement-Bayard)	7	11	53 4-5

The result has created the greatest surprise. Thery, the winner, received a magnificent ovation, and had to be rescued, with his car, from the frenzied delight of the throng who saw the finish. As will be seen, he won easily; his gross time for the 348 miles gross was 7 hrs. 48 min., and, neutralisations being deducted, he covered the 329 miles net in 5 hrs. 20 min. Thery's average speed works out at 99·4 kilometres per hour; Salleron's, 93·8 kilometres; Rougier's, 92·6 kilometres; Gabriel's, 91 kilometres; and Le Blon's at 85 kilometres. The fastest time over the measured kilometre at Mazagran was made by Duray (Gobron-Brillie) in the first round—26 2-5 secs. Thery's times over the same were 30 secs., 31 1-5 secs., 30 2-5 secs., 31 2-5 secs., and 31 1-5 secs. Salleron's ranged from 30 sec. to 33 secs., Rougier's from 29 3-5 secs. to 35 secs., and Jarrott's from 33 2-5 secs. to 41 4-5 secs.

PARIS, Saturday, May 21.

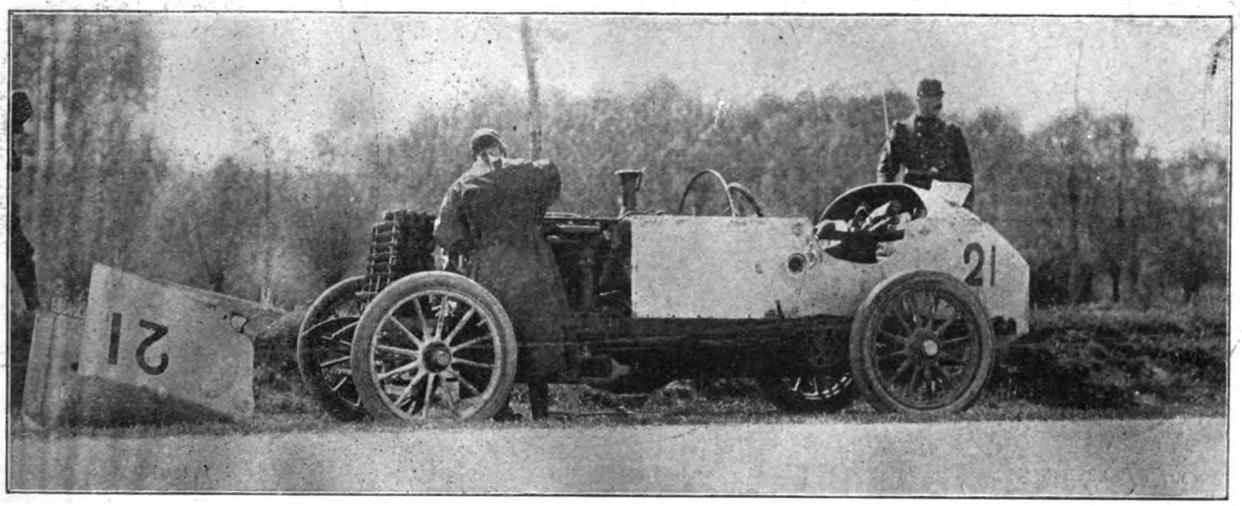
It is estimated that no fewer than 300,000 people watched the contest from one point of the course or another, and it is a striking testimony to the excellent arrangements that no accidents to the public have been reported. After the race was over there was a rush for the conveyances to the railway station at Attigny, while those at Rethel and Vouziers were equally busy.

Baron de Forest (De Dietrich) Taking the Bend at Biernes.



In what can only be described as the wild stampede of motor-cars back to the capital it hardly came as a surprise when a number of accidents were reported. Only one really serious accident occurred, and that was near Chateau Thierry, at midnight. A party was driving rapidly to Paris, when the car ran on to a heap of stones on the roadway, jumped off against a tree, and turned a somersault. Two persons in the vehicle were injured. Several other mishaps, in none of which, fortunately, were there any worse injuries to persons than cuts and bruises, occurred to motorists driving home from the race.

WE regret to learn of the death of M. H. P. Dechamps, the well-known Belgian constructor of motor-cars.



THE first German handbook to the 1904 Gordon Bennett race to reach us is that published by the Frankfurter Reklame Gesellschaft, of Frankfort-am-Main. It gives a brief *resume* of the preceding Cup races and a guide to the Taunus course. The same firm is also issuing a series of Gordon Bennett pictorial post-cards

GORDON BENNETT RACE NOTES.

ALTHOUGH all the preparations for the Cup Race in Germany are nearly finished, no official concession for the competition had until last week been obtained. The German authorities have now, however, been over the whole course, and, after a thorough inspection, announced that the concession would no longer be withheld. A commission of seventeen officials and technical experts started early in the morning from Saalburg in ten motor-cars to see if all the demands for safety and the maintenance of order had been complied with. They began with an inspection of the two grand stands erected at the starting-point, close by the old castle.

◆ ◆ ◆

FOLLOWING the direction which the competing cars will take, the road leads down a steep incline and turns into the woods of Saalburg, from which it emerges near the railway station of Wehrheim. Here Herr von Budde, the Prussian Minister for Public Works, who was one of the Inspecting Commission, declared that a bridge would have to built over the course. At this point there is another grand stand at Wehrheim, and here will possibly be the largest assemblage of sightseers, because one can follow the racing cars over a straight road through an open country for nearly five miles each way. After Limburg is passed the country becomes hilly, and the road shows a number of sharp turns. At Glashütten the road climbs up to its greatest height, about 1,600 feet, and then descends rapidly to Oberursel.

◆ ◆ ◆

A NEW decision has been arrived at with regard to the starting of the competitors in the Cup race. According to the latest plan, instead of seven minute intervals, the cars will be despatched at periods of five minutes.

◆ ◆ ◆

OWING to several of the members being called up for active military service, the Russian Automobile Club has abandoned the idea of touring from St. Petersburg to Homburg on the occasion of the Cup race.

◆ ◆ ◆

THERE is, after all, to be no American team in the 1904 Gordon Bennett race. A Committee of the A.C.A. held a series of trials of the Peerless and Winton racers on a course about three miles long near Cleveland, O., on the 5th inst. The idea of the Committee was to keep the cars running for four or five hours, now at all possible speed, again slowly and making occasional stops, but always to keep the engines going. Only one of the Peerless cars showed any speed. It ran about fifty miles, carrying one official with a stop watch, and speeding and stopping as he directed, then its change speed gear gave way, with the result of a twisted countershaft and a cracked gear case. The other Peerless was only run a few times over the course. On its second trip it had to be stopped and fitted with new sparking plugs. The best showing was made by Oldfield with his Winton Bullet car. He sped up and down twenty-two times, or something more than sixty-six miles, without a hitch. On some places he was going at the rate of sixty-five miles an hour. After his twenty-two trips, however, a pin in the driving gear of the circulating pump broke and the cooling water quickly steamed away.

◆ ◆ ◆

THE Christie 40-h.p. car was tested on the 10th inst. over a five-mile course on Long Island. Altogether thirty-eight miles were covered at an average rate of forty-nine miles an hour. At the last minute the Committee ordered the foreign carburettor to be replaced by an American one. During a preliminary running of the motor carburation troubles were apparent, but made no appearance during the actual road tr ia defective oil feed being then the only noticeable trouble.

◆ ◆ ◆

AT a meeting of the Board of Governors of the A.C.A. on the 11th inst., it was decided that the cars should be given another opportunity to prove their fitness for places in the American team, when a 200 mile run would be held on the Empire City track, at Yonkers, New York. The trials, however, proved unavailable, for, according to telegraph advice, there were only two contestants—Oldfield on the Winton, and Mooers on a Peerless. Oldfield took exception to the stringency of the regulations, and withdrew from the contest. Mooers, who covered 19¾ miles in 27 min. 43 2-5 secs., finally withdrew on the ground that there was no other competitor. As a result the Automobile Club of America has decided not to send a team to compete in the 1904 Cup race.

SPEED AND POWER, LIMITED, is the title of a company registered with a capital of £10,000, to carry on the business of manufacturers of or dealers in automobiles. The registered office is at 8B, Rumford-place, Liverpool.

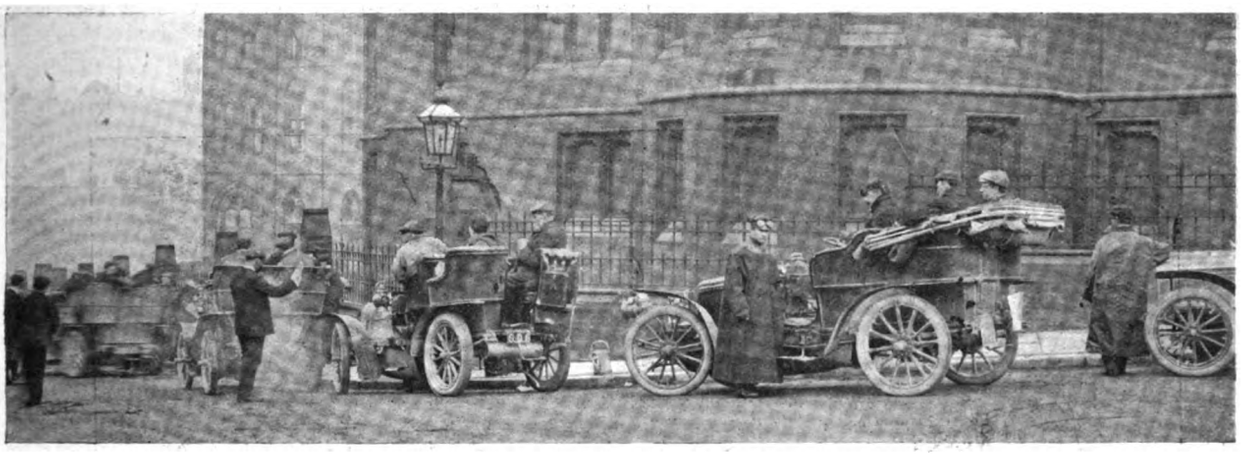
The Glasgow to London Non-Stop Run.



AGAIN the Scottish Automobile Club—or, we should say, the Western Section of that organisation—has proved its enterprise, and given its hon. secretary, Mr. R. J. Smith, an opportunity of demonstrating his capacity for organisation. Last week we were able to briefly mention the departure of the cars from Glasgow on the morning of Thursday, the 19th inst. In our issue of April 23rd, we gave a list of the entrants, of whom thirty actually started from the Scottish city.

Eagle light car, the 16-h.p. Delahaye, the 12-h.p. Siddeley, the 18-h.p. James and Browne, the 16-h.p. Rochet-Schneider, the 16-h.p. Maxim, and the 8½-h.p. Humber. The Renfrew and Vulcan cars were withdrawn, and the Spyker did not start owing to not being ready in time.

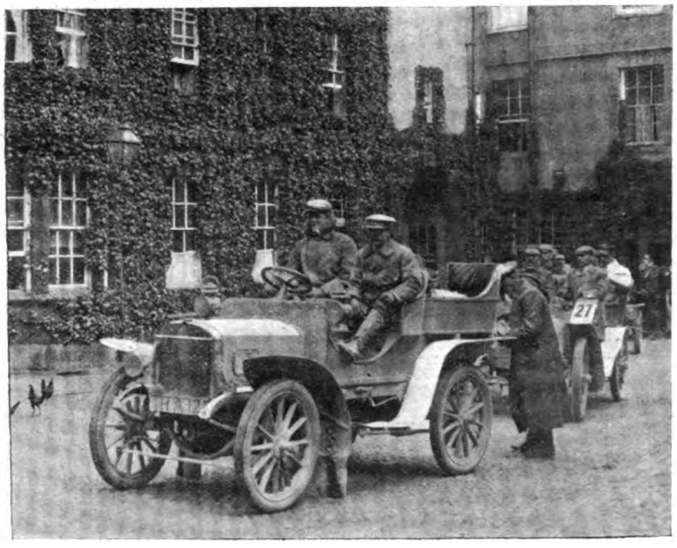
No. 3 was a 14-h.p. Renault of good repute. It was driven by Mr. McBride, of the Roadway Autocar Co., Ltd, who had entered the vehicle in the sure expectation of it receiving

The Cars in the Market Square, Penrith.

Photos by] Mr. John Adam despatching the Cars from Leeds. *[Argent Archer.*

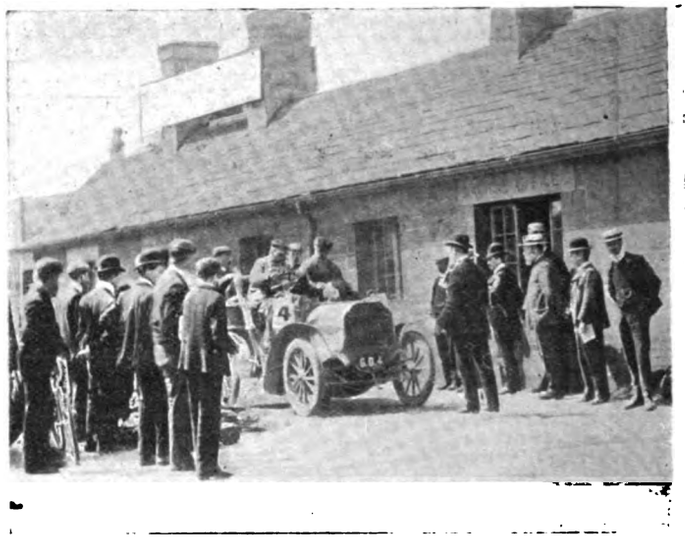
Owing to the more diversified character of the route, it was anticipated that the incidents would be more numerous than were likely to take place on the following day. This hardly proved the case, for, with the exception of a puncture of one of the tyres of Captain Deasy's Martini and the withdrawal of the 24-h.p. Eagle, nothing worth noting occurred. A halt was cried at Penrith for lunch, and all the cars duly reported themselves at Leeds by the evening.

The four-cylinder Argyll, which started eighth, arrived first; other cars which similarly improved their position and enhanced their reputation being the 10-h.p. Ryknield, the 6-h.p. Wolseley, starting twenty-fourth and arriving seventh, the a non-stop certificate, which it ultimately won. Such a combination of driver and car made up such a "unit"—to quote the term made familiar in the Eliminating Trials by the A.C.G.B.I.—as gave confidence to us, as we took our seat in the tonneau at 5.45 a.m. on the morning of Friday, the 20th. It was a cold, dull morning, and in the ashen light of the early day the party of motorists seemed almost as men without hope. They were taking their pleasures sadly. Punctually at three minutes past the hour of six Mr. John Adam gave the word to go, and we went, crossing over the tramlines and passing through the industrial district of Hunslet, with such crowds of working people as made some of the wayfarers almost forget 'twas



Digitized by Google

morning. But the population of Leeds is one of early risers. Being in the van of the procession, there were few incidents in the first few miles, but none could help remarking the excellent organisation by which posters pointing the way to drivers were shown at all the corners, a work in which the good help of the Yorkshire club had been cheerfully given to the Scottish organisation.



Beyond Oulton a curious thing happened We ran into a fog—a definite, determined sort of white cloud that enveloped the cars and made driving a speculation indeed. Curiously and cautiously the cars had to pick their way. No question of speed was likely to violate the law, and rarely have motorists had to go so gingerly as in that district; but ere Pontefract was reached the sun came out joyously and dispelled the gloom. By the time we got to the town just named and had skirted its market-place a warmth became apparent in the atmosphere, and dust rose from the road. Thanks to the fog, the cars had got into a cluster, and one or two were particularly pronounced as dust-raisers. Others, like the 12-h.p. Richardson, were going well and strong.

At Doncaster, one or two garages were passed on the way to the famous Course, and outside the Crown Hotel at Bawtry a combination of an old gipsy van and a little Renault—a small relative of our trusty 14-h.p. car—stood side by side, almost a picture of Dignity and Impudence. At Tuxford a crowd of school children awaited the arrival of the automobiles, reminiscent of the way the children were drawn up outside schools to see the cars pass on the great Thousand Miles Trial. Across some of the pleasant moors the cavalcade pursued its way, and it was noticeable how well the local postmasters have carried out the instructions of the central authorities as to the names being conspicuously painted outside. At a quarter to ten we were at Newark, a town made famous by being the first constituency of the late Mr. Gladstone. Bennington was a long, straggling village, in which Mr. J. W. Stocks was discovered at the helm of a 12-h.p. De Dion. Beyond Great Gonerby and Grantham we got into a more hilly locality—quite a change after the flat, dull level that had been encountered thus far. At twenty minutes to twelve Stamford was entered, the motor place of Messrs. Hayes and Son passed, and we strode into the old-fashioned yard of the George Inn, an unkempt, dirty, dusty set of mortals, whose appearance betokened tramps rather than men of some responsibility in the world.

After lunch—and all the cars reached the place in good time without particular incident—we were weighed—1 ton, 9 cwts., 2 qrs.—and off we set for the next stage, Biggleswade, forty-four miles away. Before reaching Wansford, one of the most charming villages seen on the whole journey, a danger board of the A.C.G.B.I. was noted. Norman Cross, with its two hotels and proneness to police traps, was left behind, and, passing through the village of Eaton Socon, we got to Biggleswade, where Mr. Dan Albone

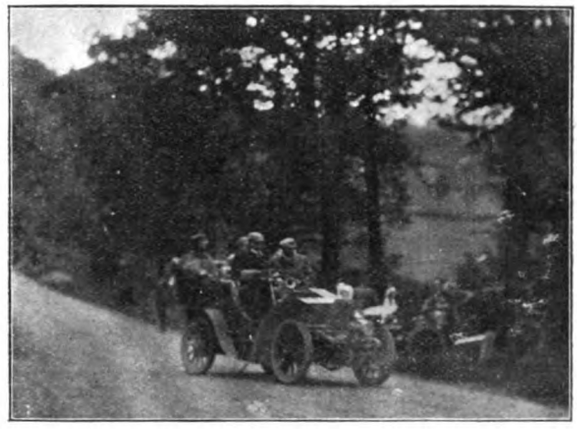
greeted all who crossed the Ivel. Hitchin was the next place of importance on the route. Beyond Langford post office was a nasty corner requiring careful negotiation to avoid a pond at the foot of a decline. We were at Welwyn at four o'clock, and then at Hatfield turned to the right for St. Albans and Elstree, from whence we went steadily towards Woodcock Hill, where the hill climb was announced to take place.

THE HILL-CLIMB AT ELSTREE.

En route, the competing cars were subjected to a hill-climbing test from a standing start on a short but stiff



Profile of Woodcock Hill, Elstree.

gradient, known as Woodcock Hill, on a cross road between Elstree and Barnet. We arrived at the spot about 4 p.m., but learned that the first car was not expected for at least forty-five minutes. The road was under repair, and indeed the road-menders were at work right up to the time the vehicles began to arrive. They had, however, considerately repaired one half of the road at a time, and that the right side, so that the competitors had nothing to complain of as regards road surface. As the time the cars were expected drew near, several motorists from London and district put in an appearance, there being about a dozen cars and as many motor-cycles drawn up on the roadside. The timekeepers, Messrs. F. Straight and H. J. Swindley, and officials had now put in an appearance, the necessary flags fixed in position and tapes laid across the road at the starting and finishing points. It was exactly 4.45 p.m. when the cry was raised, "Here comes a car," which proved to be the six cylinder Sunbeam, No. 1, driven by Mr. Pullinger. We had only time to learn from him, as he pulled up on the line, that he had come thus far on the long journey without trouble of any kind, when the timekeeper, with watch in hand, called out "Ready, five, four, three, two, one, go!" Unfortunately Mr. Pullinger made a poor start, which had serious results, for his car only got about 100 yards along the course when the engine stopped and the vehicle came to a stand. Coaxing proved

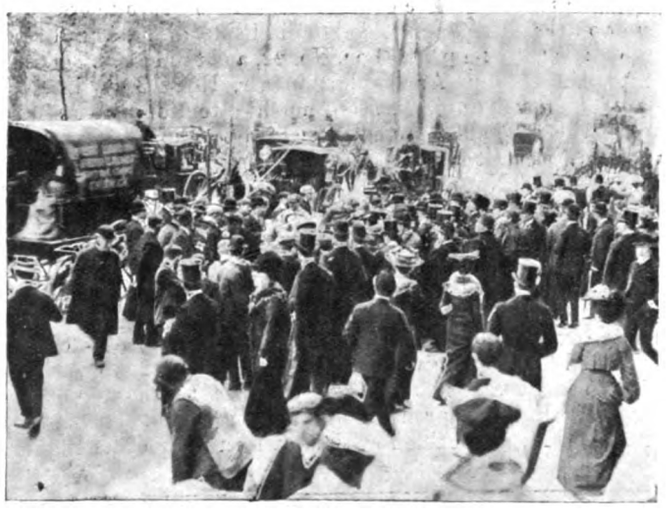
Stocks on the 12-h.p. De Dion on Woodcock Hill.

ineffectual, and another car having arrived, there was nothing to be done except to run the vehicle back on to the side of the road. The second arrival was No. 6—a 16-h.p. Argyll, with No. 4, a 10-h.p. out of the same stable, quickly on its heels, the drivers and passengers presenting a sorry sight, so thick did the dust lie on their faces and clothing. Both cars took the hill in good style, as also did Mr. Martineau on the 18-h.p. James and Browne, No. 20, who was the fourth to arrive. The doughty little 6-h.p. Wolseley, the identical car which carried us through the snow to Edinburgh in February last, was the next to put in an appearance, and the way it mounted the hill came as a surprise to the onlookers. The cars now came in rapid succession, Mr. Siddeley on the 12-h.p. Siddeley, No. 17, the 20-h p. Thornycroft, and No. 25, the 12-h.p. Eagle, No. 12, with Mr. Jackson at the wheel; all of whom went up in good style. The 12-h p. Richardson was not so fortunate, as it had to shed a passenger as it reached the stiff portion near the top. The 14-h.p. Renault, No. 3, with Mr. McBride driving, and with the representative of the *Journal* among the passengers, was now on the scene and tackled the hill splendidly, as did also Mr. Stocks on the 12-h.p. De Dion, No. 22, and the 16-h.p. Maxim, No. 24. The 12-h.p. Arrol-Johnston car, No. 13, which, by reason of its novel lines, attracted much attention, successfully mounted the hill, albeit somewhat slowly, although it must be remembered that it was carrying a load of six persons. The 10-h.p. Rykneild, No. 7, with Mr. Clay driving, which came next, had to drop a passenger ere the summit was reached. The 16-h.p. Delahaye, No. 19, was next despatched, and went up without a murmur. What may be termed two sister cars came in together, Mr. Morgan Donne on the 16-h.p. Rochet-Schneider, No. 6, and Captain Deasy on the 16-20 h p. Martini, No. 10. Both made excellent climbs, although Mr. Donne put in his clutch too soon and had to be given a fresh start. The 12-h.p. Argyll, No. 5, also made a false start, and only got to the top of the hill by being pushed by a number of willing hands. The 6½-h.p. Cadillac, No. 21, noticeable for the quiet running of its engine,

The 12-h.p. Richardson ascending the hill.

the 12-h.p. Gladiator, No. 2, with Mr. Shaw at the helm, the 12-h.p. Sunbeam, No. 14, the 12-h p. Pipe, No. 15, all made the ascent without difficulty, and, with a lull in the arrival of the cars, Mr. Pullinger made another and successful attempt to scale the hill on the six-cylinder Sunbeam. There were four stragglers still to come as we left Woodcock Hill for London, the journey being made *via* Edgware, Hendon, and Cricklewood, in order not to partake of the dust of the competing cars, which travelled *via* Barnet and Finchley, and to enable us to reach the Club in Piccadilly in time to welcome the dust-covered travellers.

Appended are the official times of the hill climb. It must be remembered, however, that the times are only a factor in the formula by which the awards are made, and that they convey nothing with regard to the definite results.



TIMES ON WOODCOCK HILL.

No.		Secs.	No.		Min.	Secs.

After the hill climb, as before, there was no excitement and no incident save one or two punctures, and by six o'clock we reached Piccadilly, having travelled the 212 miles without mishap. The Renault proved a very quiet-running vehicle, with no vibration, no worry to the driver, and altogether a most reliable and pleasurable vehicle for touring purposes.

The 12-h.p. Arrol-Johnston car, which made a non-stop run with six passengers, started on Saturday evening about eight o'clock

Scene at the arrival at the A.C.G.B.I., Piccadilly, W.
[Photo by [Baker and Dixon.

from the Automobile Club-house, 119, Piccadilly, with four passengers, on a non-stop run to Glasgow, Mr. Adam, chairman of the Western Section of the Scottish Automobile Club, being one of them, he being in London superintending the Glasgow to London non-stop trials. The car arrived in Glasgow at four minutes to 6 p.m. on Sunday, completing the total journey in one minute less than twenty-two hours. There were no stops on the journey except compulsory ones, during which the engine was kept running.

The Renfrew car entered by the Scottish Motor Garage Co. was withdrawn from the contest through a flaw in the casting of the pump allowing a leakage of water. Up to the point where this leakage was discovered, near Carlisle, each control had been passed up to the minimum time. The flaw was put right at Carlisle and the journey continued to London on Saturday morning. Leaving early, they arrived in London the same evening at 9 o'clock, covering a distance of 320 miles, and doing the journey at an average of over twenty miles per hour. They did not touch a nut or a bolt on the car during the run, beyond their misfortune to have this leakage of water in the pump.

The committee of the Scottish Automobile Club (Western Section) have issued the following statement:—

A preliminary examination of the Observers and Stewards' records has disclosed that non-stop certificates have been gained by the following cars:—

CLASS A.—Cars having one cylinder.

No. 26. 6-h.p. Light Wolseley, entered by Rennie and Prosser, Limited, Glasgow.

CLASS B.—Cars having two cylinders.

No. 4. 10-h.p. Argyll, entered by Hozier Engineering Company, Limited, Glasgow.

No. 12. 12-h.p. Light Eagle entered by the Eagle Motor and Engineering Company, Limited, Altrincham.

No. 13. 12-h.p. Arrol-Johnston entered by the Mo-Car Syndicate, Limited, Paisley.

CLASS C.—Cars having three or more cylinders.

No. 3. 14-h.p. Renault (1904) entered by the Roadway Autocar Company, Limited, London.

No. 14. 12-h.p. Sunbeam, entered by John Marston, Limited, Wolverhampton.

No. 20. 18-h.p. James and Browne, entered by James and Browne, Limited, London.

No. 25. 20-h.p. Thornycroft, entered by Thornycroft Steam Wagon Company, Limited.

The foregoing statement is subject to more minute and exhaustive examination of the records, and is not to be held as final.

The gold medal awards cannot be determined until the times recorded by the official timekeepers on the hill climbing test at Woodcock Hill, Elstree, have been worked out on the basis of the prescribed formula.

CONTINENTAL NOTES.

The A.C.F. Carburettor Competition.

The carburettor competition organised by the French Automobile Club commenced on Tuesday last. Messrs. Longuemare have entered two carburettors, Messrs. Gautreau Freres, Dourdan, three, and M. Cormerais, Nantes, M. Frossard, Ronchamps, Messrs. Hanon and Co., Paris, M. Richard, Paris, M. Saint-Denis, Bonnieres, and Messrs. Michaud and Co., Paris, one each.

◆ ◆ ◆

The Belgian National Circuit.

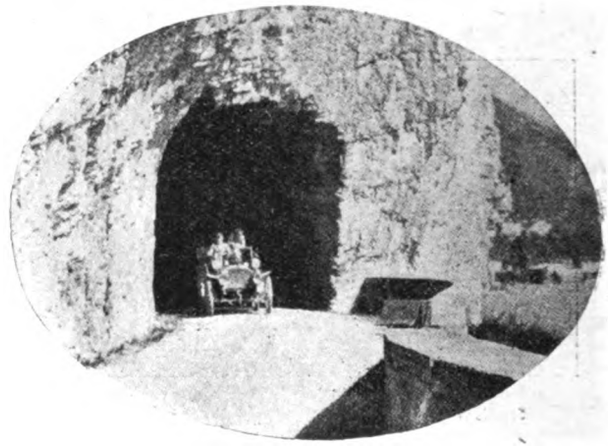
The Circuit National, organised by the Belgian Automobile Club, is fixed to start on the morning of the 30th inst. from Brussels. The first day's run is to Antwerp, and the second to Spa. On the 1st June there will be a kilometre slow race (the winner being the one who takes the longest time), and a kilometre speed trial, with flying start. The journey back to Brussels from Namur will be made on June 3rd.

◆ ◆ ◆

A Novel Balloon Chase.

A novel balloon chase is to be held on Sunday by the Lyons section of the French Aeronautical Club and the Automobile Club du Rhone, in so far that both motor-cars and horses will compete in the chase. The horses will be ridden by officers of the cavalry corps at present stationed at Lyons. We may add that great interest is being shown in the event.

◆ ◆ ◆



A Touring Competition at Lyons.

The Automobile Club du Rhone is organising a touring competition for the Rochet-Schneider Cup. The distance to be covered is about 340 kilometres, the route being Lyons, La Cluse, Saint Claude, Gex, Bellegarde, Seyssel, Amberieu, Lyons. The points which will be taken into account in making the award are—regularity of running, consumption of fuel, speed on hills. The exact date of the event has not yet been fixed.

◆ ◆ ◆

Motor-cabs in Paris.

Paris will soon be in possession of a motor-cab service. For the last two or three years motor-cabs have occasionally been seen in the streets, but they have never been popular, for the

A Snapshot near Lake Como.

reason that the tariff was too high for ordinary pockets. The authorities have found it necessary to draw up regulations concerning these new vehicles. A special commission has just fixed the rate for the hire of motor-cabs. For instance, it has decreed that one can now drive for a kilometre, which is five-eighths of a mile, in one of these cabs for 1f. 75c., and 50 centimes for every additional kilometre.

THE TURNER-MIESSE STEAM CAR.

IN our report of the recent Exhibition at the Agricultural Hall we gave a few general particulars of the Turner-Miesse steam car which is made by Turner's Motor Manufacturing Company, Limited, at their works in Wolverhampton. Judging from the enquiries we have been receiving lately there seems to be a growing interest in steam vehicles, so that the following detailed description of the Turner-Miesse may not be without interest. The cars are being made in two sizes, 10-h.p. and 16-h.p; the general design of both is identical, and is clearly shown in the accompanying illustrations. The main frame is built up of wood, stiffened with steel flitch plates and corner plates. It is fitted with five cross-members of channel section, two of which carry the boiler beneath the bonnet in front, one is beneath the dash-board, and the other two support the fuel and water tanks at the rear.

The generator, which is of the flash type is built of a number of layers of solid-drawn steel tubes, each tube being bent into a special shape. There are sixteen layers in all, laid horizontally one above the other, each layer being at right angles to the other, and each four layers connected together by outside unions. The water enters the bottom layer first and finds its way up through several of the sections before being led across some of the central sections to flow up through the upper sections. After passing through the top sections it is brought down again to the lowest of the intermediate layers, through which the steam then passes upward before passing to the engine. The lowest tubes may thus be considered to act as a feed-water heater, and are therefore not liable to become burnt under ordinary working conditions. The top layers receive less heat from the burner, and may be called the steam raising coils. The intermediate coils may in the same way be looked upon as the super-heater portion of the boiler

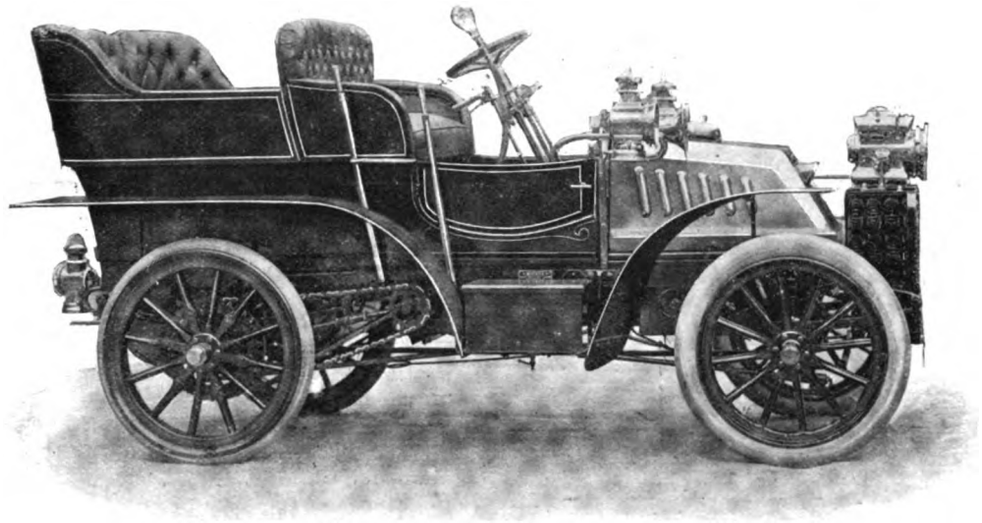

Fig. 1.—General View of Latest Type of Turner-Miesse Steam Car.

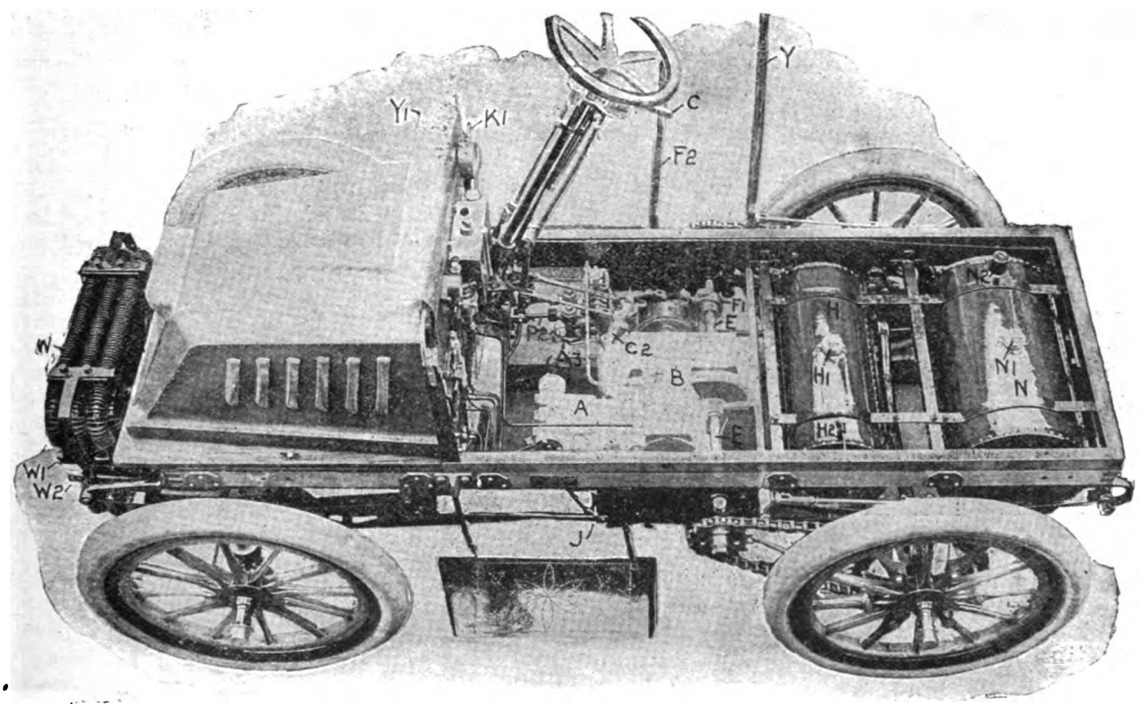

Fig. 2.—Top View of Chassis of Turner-Miesse Steam Car.

Digitized by Google

The tubes vary in thickness, although the external diameter throughout is ¾ in.; those at the bottom have an internal diameter of about 5-16 in., and the superheated coils of about 7-16 in. In the 10-h.p. generator the total length of tube is about 200 feet, and in the 16-h.p. car, roundly 300 feet. The generator is enclosed in a special casing, built up with an inner and outer sheet of steel, held together by channel steel frames top and bottom, the space between the metal sheets being filled up with asbestos. The cover above the generator tubes is formed of a plate having three long rectangular holes in it, and made to form the bottom of a horizontal flue, a second bent plate being fixed above it. This flue runs out through the bonnet in front, and is connected with a vertical flue passing down between the

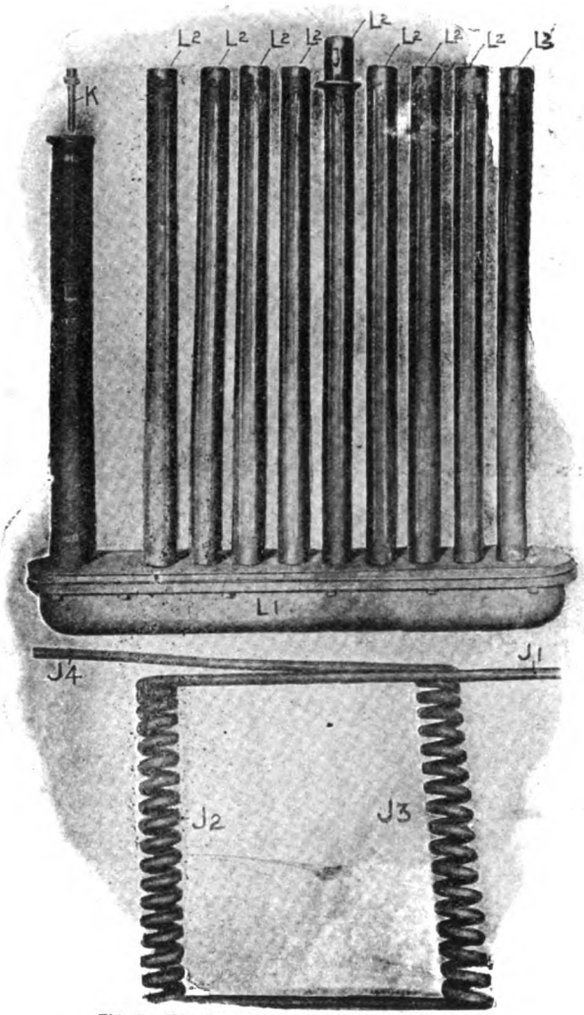

Fig. 3.—The Turner-Miesse Burner and Vaporiser.

generator casing and the hollow dashboard, the burnt gases passing out through it beneath the car.

The generator, which is tested to a pressure of 1,200 lbs. per square inch, is fired by a special form of burner which uses ordinary paraffin as fuel. The latter is carried in the air-tight tank H. (Fig. 2); the feed-pipe from it is led to a shut-off cock on the left-hand side of the car. A pressure of about 40 to 50 lbs. per square inch is maintained in the tank by a mechanically-driven air pump worked directly off the crank shaft of the engine. The delivery pipe from the pump is led to a three-way cock, which is connected with a gauge showing the pressure in the fuel tank, and with a relief valve on the dashboard. The three-way cock has a nozzle to which can be attached an ordinary tyre pump for obtaining the necessary pressure initially. The fuel finds its way through two vaporiser coils which lie above the burner and the regulating valve to the burner nozzle. The quantity of gas which is fed to the burner is regulated by a hand lever, K^1, on the dash-board. No regulator for the air is provided; the air and gas pass along the pipe into a chamber from which a large number of parallel horizontal tubes project beneath the boiler. The tubes are perforated with rows of fine holes, drilled at an angle, which form the burner jets. The oil enters one end of the vaporiser which rests directly on two of the main burner tubes, passes through the various spirals and emerges at the other end as vapour. A view of the vaporiser is given in Fig. 3. The burner is placed in line with a hole in the casing, through which the flame of the pilot light is introduced. The vaporised oil passes through the pipe, J^4, and through the hand regulator to the burner jet. The vaporiser has an internal bore of 5-16 inch and an external diameter of 9-16 inch. An inspection hole in the generator casing allows the operator to see when the coil J^3, is sufficiently heated by the pilot light to permit the paraffin cock to be opened. The burner is also illustrated in Fig. 3, the nozzle, K, through which the vaporised oil passes, being shown withdrawn from the mixing pipe L. The latter is open to the air at the end into which the nozzle K projects. The pipe leads into a chamber L^1, which is made in two parts so as to allow the burner tubes, L^2, to be fixed into it, and to permit of cleaning out when necessary. The tubes, L^2, are perforated, the two external tubes having but one row of holes in them, and the other tubes two rows. The mixture of gas and air issues out of these holes at an angle of 45 degrees, and the flames from each adjacent tube strike one another and cause the heat generated to be equally diffused. The burner is slid in through holes which are bored for each of the pipes, L^2, in the front and back of the generator casing. The mixture supply tube, L, lies outside the casing, while the central tube, which is somewhat longer than the others, projects through at the back. It is slotted near its end so that the burner may be fixed in place by a wedge-shaped cotter key fitting in the slot. All the tubes are, of course, closed at their rear ends. The 10-h.p. burner has seven tubes and the 16-h.p. nine. Even the smaller burner has over a thousand small holes in its tubes. The hole through the nozzle, K, is extremely small, being only about 1-16 in. in diameter. The burner can be easily taken out when necessary, the pipe connection to the nozzle and the cotter behind the generator casing, alone requiring removal before drawing the burner out forwards from the car. The vaporising coil of the burner is initially heated up by a pilot lamp and subsequently kept hot by the burner itself.

The vaporiser coil requires to be thoroughly heated by the pilot light before attempting to start the burner with its ordinary fuel. The operation of heating up takes something over five minutes to perform, but should not be hastened unduly, as the burner is liable to smoke if the coil is not sufficiently hot. The burner appears to work well and quietly, and to give a very high degree of heat.

(To be continued.)

THE Maidstone Town Council has withdrawn its application to the Local Government Board with regard to the ten mile speed limit.

THE Massachusetts Society for Prevention of Cruelty to Animals has appointed a committee to consider the question of purchasing an automobile ambulance.

IN a case at Epsom, where he secured the conviction of a motorist, P.C. Pearman said he could dissect a watch and put it together again. I have, he added, "served an apprenticeship to the watch-making trade."

THE vehicles which are being used by the South Hams Motor Carriers, Limited, for their new service between Modbury and Plymouth are of the Milnes-Daimler eighteen-seated single-deck type. We had an opportunity of inspecting one of the 'buses last week, prior to its despatch. The road wheels are shod with Peters' solid rubber tyres, those on the rear wheels being of the twin type.

THE LONDON-EDINBURGH MOTOR-CYCLE RUN.

OUT of the seventy entries for the twenty-four hours' run from London to Edinburgh, a distance of 400 miles, organised by the Motor-Cycling Club, forty-six competitors started about 10 p.m. on Friday night last week from the General Post Office. Soon after half-past nine the preliminaries were completed, and, with Mr. C. W. Brown, hon. secretary of the trials, at their head, the competitors filed out of Paternoster-square for the G.P.O. Stops for meals were made at Grantham, Wetherby, Durham, and Berwick-on-Tweed. The checking points were:—Biggleswade (45 miles), Grantham (110¼ miles), Tuxford (137¾) miles), Wetherby (193½ miles), Durham (259½ miles), Alnwick (308 miles), Berwick-on-Tweed (338 miles), Dunbar (368 miles), and Levenhall, Musselburgh (390 miles). At Wetherby, which was "controlled" from 8.10 to 9.30 on Saturday morning, the following had arrived by 10 a.m.—C. W. Hacking, 3 h.p. Ormonde; F. Hulbert, 2¾-h.p. Bramley; Chester Fox, 2¾-h.p. Special Vindec; J. Platt-Betts, 3-h.p. Rover; W. H. Wells, 2¾-h.p. Vindec Special; H. Williamson, 3¼-h.p. Rex; J. H. Reeves, 2½-h.p. R. and P.; A. Candler, 3 h.p. Quadrant; A. Wright, 3-h.p. Roc; W. A. Sale, 2-h.p. Quadrant; C. W. Brown, 2¾-h.p. F. N.; A. S. Wilson, 2¾-h.p. Ormonde; J. Van Hooydonk, 3½-h.p. Phœnix Trimo; H. J. Densham, 2¾-h.p. Anglian; H. E. Cowles, 2¾-h.p. Minerva; C. E. Bell, 3-h.p. Quadrant; E. T. Arnott, 4-h.p. 2 cylinder Princeps; T. Silver, 4½h-.p. Quadrant Tricar; T. Hooydonk, 3½-h.p. Ariel; J. F. Crundall, 2¾-h.p. Humber; F. J. Heighton, 3½-h.p. Vinco Tricar; W. J. Milligan, 2¾-h.p. Bradbury; D. Elyard Brown, 3-h.p. Ormonde; and A. H. D'Aeth, 2¾-h.p. Humber. At Durham, 18 had arrived by 12.30 p.m. on Saturday, Reeves, Candler, J. Van Hooydonk, Crundall, and C. W. Brown being among the number. Seven more, including Milligan and Elyard Brown, passed through shortly after.

Twenty-two of the forty-six competitors who started from London succeeded in the attempt to reach the Edinburgh General Post Office in twenty-four hours, and thus gained gold medals. Nine riders covered the distance in twenty-two hours. The successful competitors were:—F. H. Arnott (3-h.p. Werner), C. E. Bell (3-h.p. Quadrant), C. W. Brown (2¾-h.p. F. N.) D. Elyard Brown (3-h.p. Ormonde), A. Candler, (3-h.p. Quadrant), H. E. Cowles (2¾-h.p. Minerva), J. F. Crundall, (2¾-h.p. Humber), H. J. Densham (2¾-h.p. Anglian), Chester Fox (2¾-h.p. Special Vindec), C. W. Hacking (3-h.p. Ormonde), J. Van Hooydonk (3½-h.p. Phœnix Trimo), T. Hooydonk (3½-h.p. Ariel), F. Hulbert (3-h.p. Hulbert-Bramley), H .P. Maffert (2¾-h.p. Butt), W. J. Milligan (2¾-h.p. Bradbury), J. H. Reeves (2½-h.p. R. and P.), W. A. Sale (2-h.p. Quadrant), T. Silver (4½-h.p. Quadrant Tricar), W. H. Wells (2¾-h.p. Vindex Special), H. Williamson (3¼-h.p. Rex), A. Wright (3-h.p. Roc), and L. H. Young (2¾-h.p. Werner).

COMPRESSION.

WHAT is the most advantageous compression to use in motor-car engines is still an open question. Designers of high speed vertical motors generally advocate a high compression, as it gives a lighter motor for a certain power, or a more powerful motor for a certain weight, and, besides, insures greater fuel economy. In slow speed horizontal motors, on the other hand, the compression is usually kept low, as a high compression would necessitate a very heavy flywheel, make the starting of the motor more difficult, increase the vibration and add to the strains on the working parts of the motor. There are therefore a number of reasons both for and against high compression.

In studying the problem account must be taken of the fact that at present nearly all motors are fitted with throttle control and work with maximum compression only when the throttle is wide open. Cars with an abundance of power are most of the time being run on the throttle; that is, the cylinders receive only a partial charge and the compression is below the maximum for which the engine is designed. In such an engine the advantages of a low or moderate compression are therefore secured when the power required is considerably less than the maximum which the engine will develop, while at the same time the advantages of high compression may be had where these are desirable, as in travelling over heavy roads, in climbing hills, etc. Hence it would seem, remarks the "Horseless Age," advisable always to design an engine for high compression, and the only reason against it is that the owner may not operate the car properly and run on full throttle all the time, regulating his speed by the ignition, which would be wasteful. There would be certain advantages in so arranging the throttle lever that it could ordinarily be operated only to open the valve far enough to admit about 70 to 80 per cent. of the full charge, but by making some alterations in the connections or by moving the stop for the lever allow it to be opened fully.

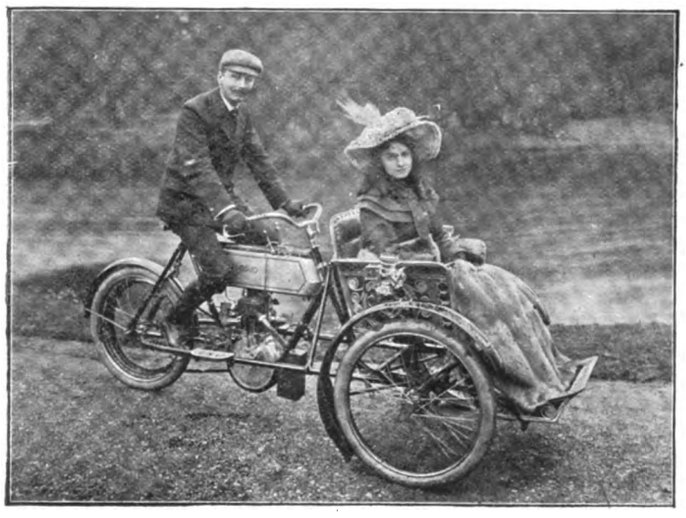
MOTOR-CYCLING NEWS.

THE Auto-Cycle Club is just now considering information which has lately come to hand concerning the greasy state of the tram lines in many of our great cities and metropolitan boroughs. It is suggested that these are watered with a frequency that leads to a practically continuous greasy condition, a condition that is positively dangerous to motor-cyclists and others travelling in their vicinity. Unfortunately, there is no central organisation of the tramways, as is the case in the railway system of the country, and the suggestions for improvement will have to be made to the individual companies or corporations concerned. Under these circumstances the need of securing considerable local support will devolve upon those motor-cyclists in various parts of the country likely to benefit by any action which the Auto-Cycle Club may take. Hence the necessity for those who are interested in the matter to give all the information they can as early as possible to Mr. F. Straight, the secretary of the Club, at 119, Piccadilly, W.

◆ ◆ ◆



MR. ALBERT BROWN, of Messrs. Brown, Bros., Ltd., has presented a handsome trophy, value 25 guineas, to the Motor Cycling Club, for competition in a 250 miles non-stop run, confined to British built machines. The contest will be an open event, and the winner will secure the trophy outright.

◆ ◆ ◆

THE combined run to Great Yarmouth organised by the Auto Cycle Club is to be held to day (Saturday). Riders are requested to meet at the Old Salisbury Arms, High Barnet, at 10 a.m. The start will be made at 10.30 a.m. sharp, the route being *via* Hatfield, Hertford, Ware, Puckeridge, Barkway, Barley, Newmarket (lunch at Victoria Hotel), Bury St. Edmunds, Harleston, Bungay (tea, King's Head), Beccles, Yarmouth. Total, 126½ miles. The return journey on Sunday will be *via* Ipswich, Colchester, Chelmsford, Dunmow, Bishops Stortford and Ware. The headquarters of the Club at Great Yarmouth will be the Queen's Hotel. Arrangements have been made with Mr. F. Flanders, 11, Regent Road, Great Yarmouth, to supply petrol, etc.

◆ ◆ ◆

THE Catford Cycling Club will hold its annual touring motor-bicycle hill-climb at Westerham on June 11th. Instead of

The Ormonde Motor Fore-Carriage.

simply a weight limit, as last year, there will be a class for engines not exceeding 70 by 70 mm., and a class for over 70 by 70 mm and not exceeding 80 by 80 mm. A sealed handicap will be run in conjunction with each class. Gold medals are being offered in each section, and the Catford Club will present three prizes for each handicap, while illuminated certificates with time affixed will be given to all who complete the course without dismounting. Pedalling will be allowed, it being considered that Westerham Hill is an exceptional hill for ordinary touring motor-cycles. All machines must be fully equipped for the road, including mudguards. It is desired to make the test a genuine trial of touring motor-cycles.

◆ ◆ ◆

MR. E. J. STEEL accomplished a notable performance on a 3-h.p Rover motor-bicycle on Wednesday last week. Leaving

Mr. E. J. Steel on his 3-h.p. Rover Motor Bicycle.

Edinburgh at 3 o'clock a.m., Mr. Steel started for London, with no idea of record-breaking. He made a non-stop run to Newcastle (121½ miles), where he stopped for breakfast, then went on to Doncaster, pulling up at Northallerton *en route* for petrol, and at York to send off some telegrams. Doncaster (237¼ miles) was reached at 2.40 p.m., and here Mr. Steel halted for an hour for dinner. Then going on by Grantham and Norman Cross, he reached the G.P.O., London, at 11.47 p.m., having covered the 400½ miles in 20 hours 47 minutes. His actual riding time was 19 hours. The machine was an ordinary 3-h.p. Rover machine, with belt drive, and neither rider nor machine were in any way specially prepared for the journey.

◆ ◆ ◆

THE number of foreign motor-cycles imported into this country during the four months ending with April last is returned at 457, their value amounting to £14,771.

◆ ◆ ◆

THE awards in respect of the Auto-Cycle Club's hill-climbing competition on the 14th inst. have been made known. The hill had a length of about 750 yards. In Class 1, for machines having motors of a cylinder capacity not exceeding 70 by 70 mm., Mr. A. A. Chase on a Chase machine was the winner, his time being 1 min. 2 1-5 sec. Class 2, up to 76 by 76 mm., was won by Mr. F. R. Goodwin (Griffon), time, 48 1-5 sec. Class 3, up to 80 by 80 mm., by Mr. A. A. Chase (Chase), time, 44 2-5 sec.; and Class 4, fore-carriages, side-cars, and trailers with two persons up, by Mr. F. W. Chase (Chase), time, 1 min. 6 4-5 sec. The award of the gold medal for the most meritorious performance was made on a figure of merit arrived at by the following formula:— $\frac{W}{C \times T}$, where W = weight of machine and rider, C = volume swept out by piston, and T = time taken to climb the hill. Under this formula, Mr. J. van Hooydonk was awarded the gold medal for the performance of his two-speed Phœnix Trimo, on which he has now travelled over 3,000 miles. Mr. Hooydonk climbed the hill in 1 min. 20 2-5 secs.

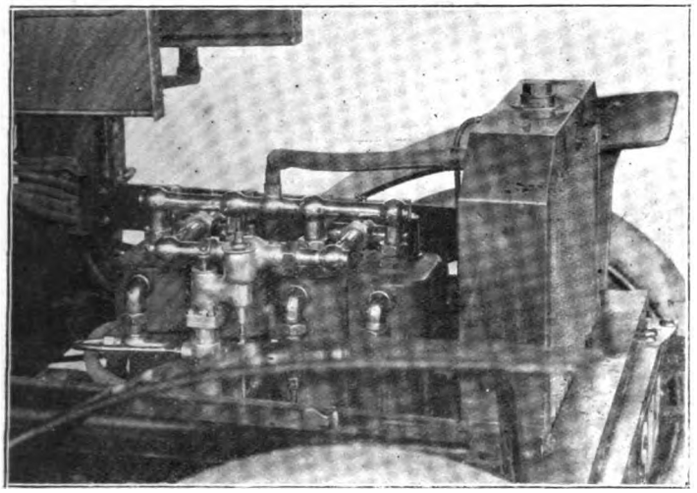
HERE AND THERE.



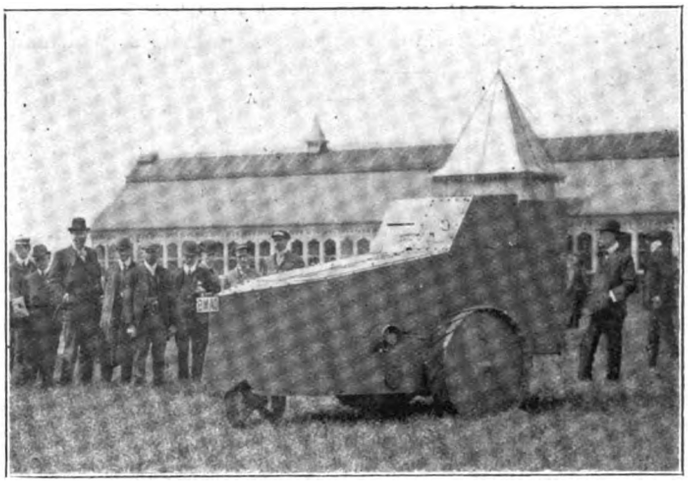
THE West Ashford Rural District Council have decided to fix danger boards at a dozen points within the area of their jurisdiction.

A MOTOR-OMNIBUS SERVICE is about to be started from Strand to Babbicombe, which, although part of Torquay, is two miles from a railway station.

AT a meeting of the Junior Institution of Engineers, on Friday, last week, a paper on "Practical Notes on the Running of Motor-Cars and Cycles" was read by Lieut. W. G. Windham.

PARISH'S CYCLE STORES, 47, Fishergate, Preston, have just secured extensive premises in Charnley Street, in the centre of the town, for a motor garage, which they intend keeping open night and day. There is room for the storage of over twenty large cars at one time, while repairs will be made a speciality.

THE Forman Motor Company, Limited, Coventry, have now completed arrangements for the conversion of single or double-cylinder engines to double or four-cylinder respectively. The accompanying illustration depicts a Clement car which has been converted, the double-cylinder engine having been replaced by a Forman four-cylinder motor, and, as can be readily seen, the details have been carried out very satisfactorily. We understand that in the trial run the engine ran very smoothly, the car showing a marked improvement in hill-climbing capabilities. The petrol consumption of the four-cylinder fitted with the Forman automatic carburettor was, we are informed, no more than with the old two-cylinder engine.



UNITED MOTOR INDUSTRIES, LTD., have recently put on the market a contrivance to get over the trouble of tail lamps jolting out. They are now supplying with their ordinary oil tail lamps a little electric light attachment, made to screw into the container of the oil lamp in place of the burner. It is such a good fit that the firm recommend carrying the container filled with oil even when the electric lamp is in position, so that the oil burner can be replaced if the electric light fails.

So many conflicting and erroneous reports concerning the fire at the Cadillac motor-car factory in the United States have been current that the Anglo-American Motor-Car Company, Limited, the agents for the Cadillac cars in this country, ask us to mention—firstly, that the fire did not destroy the whole of the plant, but was confined to the assembling room; secondly, that it was caused by neither the ignition nor the explosion of petrol, but originated in a somewhat peculiar manner. The supply tap of a riveting machine burning crude oil was accidentally opened by a workman passing the machine, who struck it with his elbow; the oil caught alight and flowed from the tank on to the floor, where the fire spread with such rapidity that it completely destroyed this department of the factory. Fresh arrangements have been so quickly made that the works are by now once more in full operation.

THE Prince of Monaco has just made a journey from Monte Carlo to Paris on a motor-cycle.

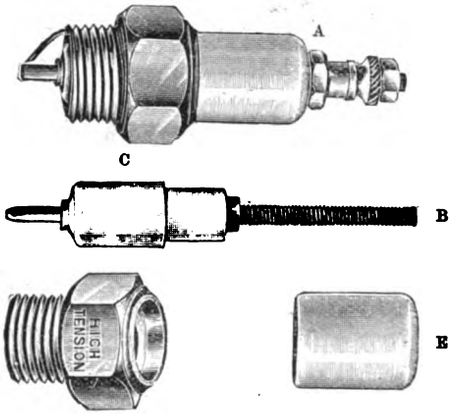
THE County Surveyor of Hampshire at Winchester is inviting tenders for the supply of cast-iron warning posts.

The Ivel First-Aid Armoured Motor at Bisley. (*See page 254 last issue.*)
Photo. by [*J. T. Newman.*

THERE are now 90 motor-cars and motor-bicycles registered in Stirlingshire, and the number of licences issued to drivers is 119.

THE Dublin, Wicklow, and Wexford Railway Company is putting on the road, between the Railway Station of Shillelagh to Newtownbarry, a motor-car for the conveyance of passengers as well as of goods traffic.

FROM the Honorary Secretary of the Motor Cycle Club comes a copy of the Club hand-book that has just been issued. In addition to a list of officers and members, this contains the full rules of the Club, and also much other information of use to the members.



MESSRS. J. W. BROOKE AND CO., LIMITED, of Lowestoft, have sent us a photograph of a yacht's tender they have just built and engined for Mr. J. Hamilton Benn, owner of the yacht "Hesper." The boat, which was designed by Mr. F. Shepherd, is arranged to be slung in the davits, and is 17 feet long by 4 feet 6 in. beam and fitted with a three-cylinder 14-h.p. Brooke engine. The absence of vibration and noise are particularly noticeable features of the boat, which has maintained a speed of 9·2 miles an hour.

The above illustration shows one of the latest Orion Petrol Lorries. The vehicle was driven by road from London to Swaffham, and has been working each day, Sundays included, for the past fortnight conveying milk from Pettygards Hall, Swaffham, to Caley's Chocolate Factory in Norwich, a distance of 26 miles, loaded, in 3½ hours.

Digitized by Google

MESSRS. PERCY HARRISON, LIMITED, Birmingham, have recently introduced the new sparking plug illustrated herewith. It is known as the "P.H. No. 2," and has been designed to overcome the constant source of trouble of porcelains breaking, through unequal contraction and expansion. It will be seen from the illustrations that the porcelains C and E are made in two parts. The porcelain C is fixed to the spindle B, which in

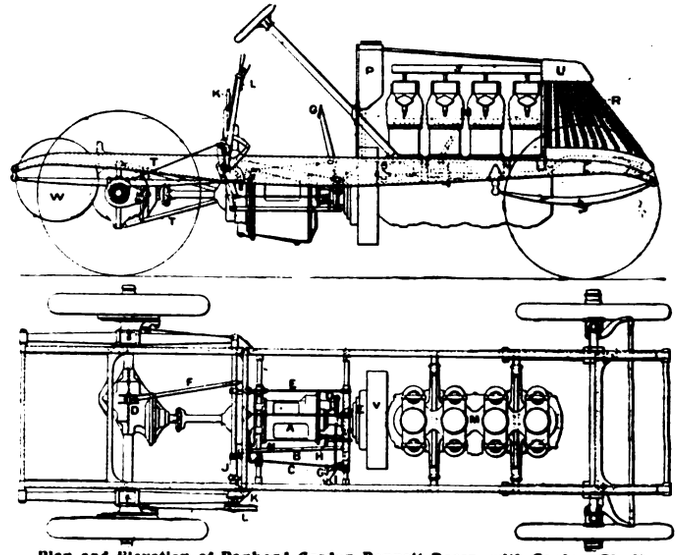
turn is inserted into the brass hexagonal nut D. The porcelain E, being bell shaped, is then placed over the spindle, fitting up against a shoulder formed in the hexagon nut, the whole being held together by the nut A, which pulls the two porcelains up against the shoulder in the nut, and with the help of a little asbestos packing makes a perfect gas-tight joint. Very little strength is needed to screw up the nut A, in fact a perfectly tight joint can be made by screwing up with the thumb and finger. The plug is supplied with terminal, copper and asbestos washer with wood dome on the end to protect the points.

THERE has just been completed at the factory of the Electric Vehicle Company, of Hartford, Conn., what is believed to be one of the largest automobiles ever built. The car, which, because of its shape, has been termed "The Whale," has a capacity of 56 passengers. It has been built for advertising purposes and will shortly be sent to St. Louis, where it is to be used for sight-seeing purposes at the exhibition. The car is driven by four electric motors, one attached to each wheel.

THE accompanying illustration shows the combination tail lamp and number plate which has been brought out by Messrs. Lowe, Bevan and Co., of Birmingham, to meet the new requirements. The feature of the lamp, which burns paraffin and shows a red light to the rear, is the provision of an automatic shutter

which acts as a reflector to illuminate the number plate, enabling figures and letters to be seen at any angle. The automatic shutter can be closed during the daytime to prevent, in dry weather, any dust getting on to the glass, and in wet weather to stop mud being thrown on the glass and reflector. We may add that the lamp is made in three sizes, according to the size of the number plate.

"WATERMOBILE" is the newest of the many suggested definitions for the motor-boat.



ACCORDING to the Natal Customs returns the value of the imports of motor-cars into that colony last year amounted to £8,203.

THE Sligo Motor Service Company, Limited, has been registered with a capital of £750 for the purpose of running motor-cars between Sligo and Ross's Point and between Sligo and Bundoran. The registered office is at Bridge Street, Sligo.

THE Upper Norwood Ratepayers' Association suggest that the neighbourhood of the Crystal Palace and Upper Norwood, being quite unprovided with any kind of public conveyances, affords a desirable area for a motor-car service.

FROM the Wolseley Tool and Motor Car Company, Ltd., comes a copy of their 1904 catalogue—an exceedingly well-got-up booklet which gives very clear illustrations of the various types of Wolseley cars, ranging from 6-h.p. to 24-h.p. The list includes a description of the cars, in which the motor, ignition, water cooling, change-speed gear and transmission are fully dealt with.

WE have received from Messrs. J. C. Lyell and Company a sample of a new metal they are putting on the market. It is known as "Patrick" metal, and is claimed to be a perfect sub-

Plan and Elevation of Panhard Gordon Bennett Racer, with Cardan Shaft Transmission.

[*La Vie Automobile.*

stitute for nickel, and to possess many advantages over nickel-plated goods. It is silver white through and through and keeps its appearance and brilliancy permanently. The metal retains a very high degree of polish and with ordinary care will not rust even under unfavourable conditions. It is malleable to a degree when cold and will easily solder and braze, the flux for this metal being the ordinary soldering water or powdered borax. "Patrick" metal is supplied in the rough state in ingots only for casting purposes and in finished state in motor-car fittings and accessories of all descriptions.

IN answer to Mr. Scott Montagu, who asked whether his attention had been called to the case of Mr. Macleod, who had been summoned at the West London Police-court for an alleged infringement of section two, subsection (*b*), of the Motor Car Act, 1903; and whether, in view of the fact that the special trader's licence and number plate had hitherto been held to cover the case of motor-cars used by a trader in the pursuance of his business, he would state what action he proposed to take, Mr. Akers-Douglas in a printed reply to the House of Commons said:—I am informed that the point at issue in the case to which my hon. friend refers is whether or not the car in question was being used by a trader in pursuance of his business so as to bring it within the enactment quoted. I can express no opinion with regard to a case pending in a court of law.

CORRESPONDENCE.

QUERIES *RE* MARSHALL CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—I have read with some amusement, not unmixed with astonishment, the effusion of "Amateur" in the last issue of the *Journal*. The writer appears to be smarting under a sense of disappointment with some car he has bought, and to be seeking to solace himself by covert attacks on a firm of well-known tyre makers and an equally well-known firm of car builders. I rather fancy it will take more than "Amateur's" diatribe to convince anyone in the know that a 1902 Marshall car steers badly for any reason other than his own incompetence; the very fact that he wants to go up hills on the top speed stamps him as an "amateur" indeed. He is one of those who certainly ought not to be trusted with a car equal to even his twenty-five miles, especially if there be any "old woman" to save himself on the same road at the same time. I have had some experience (as a passenger) of a "second-hand" Marshall car in a hilly district, and most certainly that particular car suffered from none of the drawbacks specified; but then it was not being handled either by "Amateur" or an old woman, and I should be inclined to advise "Amateur" (he asks for advice) to put the car into the hands of some one who knows how to manage it; he evidently does not. As for his back-handed attack on the tyre and car makers, nobody who knows aught of either will attach the slightest importance thereto.—Yours truly,

Streonshalk.

To the Editor of *The Motor-Car Journal.*

Sir,—If "Amateur" would like to write to me, I would be happy to try and answer any questions or give information about the above car, as I have had one for some time. I am surprised at his experience with the manufacturers, as I have found them most obliging and prompt on many occasions.—Yours truly,

Walter Keating, Jun.

Sibyl Hall, Raheny, co. Dublin.

PROPOSED ALTERATION OF BOILER.

To the Editor of *The Motor-Car Journal.*

Sir,—"Oxon" will not be able to fit a flash boiler to his Locomobile without great expense, and, when finished, it will not give satisfaction, the engine not being suitable for flash steam. The bore of cylinder is too large, and would require a very large generator; and, again, the superheated steam would destroy the packing in the glands in a few minutes. Furthermore, I do not think the construction of engine would stand the increased pressure of steam. If "Oxon" fitted a superheater to his boiler he would find a great advantage. The other day I went fully 24 miles on two gallons of spirit and less than a tank of water, my car being size 2½ and of an old pattern.—Yours truly,

W. T. Warne.

Grand-Duke Boris Wladimirowitsch on Count Josef Potocki's 35-h.p. Mercedes. [*Allgemeine Automobil Zeitung.*

CHARGING ACCUMULATORS.

To the Editor of *The Motor-Car Journal.*

Sir,—As a supplement to your answer to "Rallentare's" query in the issue of the *Journal*, may I point out there is a much more economical method than the one you suggest—namely, to connect the cells up to the terminals of an ordinary tumbler switch, of course leaving the switch blade in the open position, or short circuit will result.

All that is necessary is two short lengths of bell wire, 18 g. for preference, then, after slackening the terminal screws, force a wire into each

Digitized by Google

socket. After testing for polarity connect up the cells in the usual way, using the lamps and wiring controlled by this particular switch as a resistance. By this way the lamps can also be usefully employed instead of burning to waste. I usually charge my cells at night when the light is needed, thus killing two birds with one stone.—Yours truly,

P. H. A.

THE ACCIDENT TO MR. EARP.

To the Editor of *The Motor-Car Journal.*

Sir,—I shall be greatly obliged if I may thank, through your paper, the number of very kind friends who have enquired about my recent accident. I am pleased to say that it proved to be of a very slight nature, and I am now about again in good health.—Yours truly,

W. Clifford Earp.

TOURING IN IRELAND.

To the Editor of *The Motor-Car Journal.*

Sir,—I should be greatly obliged if any of your readers, who have done any touring in Ireland, would be kind enough to give me the benefit of their experience. I want to get away from the beaten track for a few weeks' fishing, and should much like to take a car and be independent of railways, if it would not greatly increase the cost. Any information as to route, approximate cost of shipping car (weight about 17 cwt.), facilities for getting petrol, etc., and also especially the suitability of the country roads for motoring, would be greatly appreciated.

Having heard something of the other side of the question, it is a pleasure to record the following instance of promptness and courtesy. Arriving a short while ago, late one afternoon, in the neighbourhood of Stow-in-the-Wold, in the Cotswolds, with accumulators running dangerously low, I learned, to my surprise, that the little town boasted of the possession of motor works. The proprietor lent me a spare accumulator to take me to the village at which I was spending the night, started his engine, and sat up till 2 o'clock in the morning with my two sets of accumulators, which I found ready for me the next day, and all for the sum of three shillings.—Yours truly,

H. V. F.

A PROPOSED INSTITUTION OF AUTOMOBILE ENGINEERS.

To the Editor of *The Motor-Car Journal.*

Sir,—It is with great surprise that I read the letter from Mr. J. F. Marshall in your issue of the 14th inst., and would draw his attention to the "Automobile and Cycle Engineers' Institute," which is already in existence and carrying out all of the objects as laid down in his letter with the exception of 5 (Testing Department).

For some years now this Institute has done good work in the interests of, and for, the profession of cycle engineers; but, at the last annual meeting, the Council of the Institute, having realised that a great number of its members were associated with automobile engineering, recommended that the title be altered so as to include the profession of automobile engineers. This suggestion met with the unanimous approval of the meeting, as was announced in the various Press notices, and as a result applications for membership are being received daily, and will be dealt with at our next Council meeting. In view of the foregoing, I cannot help thinking that a "proposed" Institution of Automobile Engineers is unwarranted and therefore quite unnecessary.—Yours faithfully,

H. Austin.

President of The Automobile and Cycle Engineers' Institute.

COST OF OPERATION.

To the Editor of *The Motor-Car Journal.*

Sir,—I have just read with great interest Lord Churchill's account, in the *Journal* for the 14th inst., of his costs for a year's run on a 14-h.p. Daimler. I wrote you last week asking for information *re* Collier tyres, and this seems to come as an answer. In one year the cost for repairs is £23 17s. 7d. for 3,000 miles. This must be an eye-opener to the users of these tyres, and no wonder my tyres are in such a bad state, for they have certainly, as far as I can make out, run the same distance, or thereabouts. But I cannot make out how such a figure could be run up for mere repairs; the tyres themselves—that is, the covers—cost, catalogue price, £9 each for such cars, and surely one or more must have burst entirely to run up such a bill. Mine are not burst as yet, but I must own I expect them to blow up every time I go out, and no doubt if a long journey were taken three of them would be gone before that journey's end. It would be most interesting to know how the tyres gave way and what repairs were made. My covers are of 1902 make; Lord Churchill's will be of the latest pattern, and, from testimonials sent out by the firm, should run thousands of miles, and no spare cover is necessary, so say the firm.—Yours truly,

Amateur.

STEAM CARS.

To the Editor of *The Motor-Car Journal.*

Sir,—I should like to have the experience of any of your readers who have used a Locomobile steam car for some time. I have been discouraged from buying one by being told that, though very pretty, it is really nothing but a toy and is too flimsy for real use. I cannot myself see why, with ordinary care, and without overloading or running too fast on too rough roads, it should not keep in order. I should like also to know what it usually costs for petrol per mile, and if it is satisfactory with a petroleum burner.—Yours truly,

Saunterer.

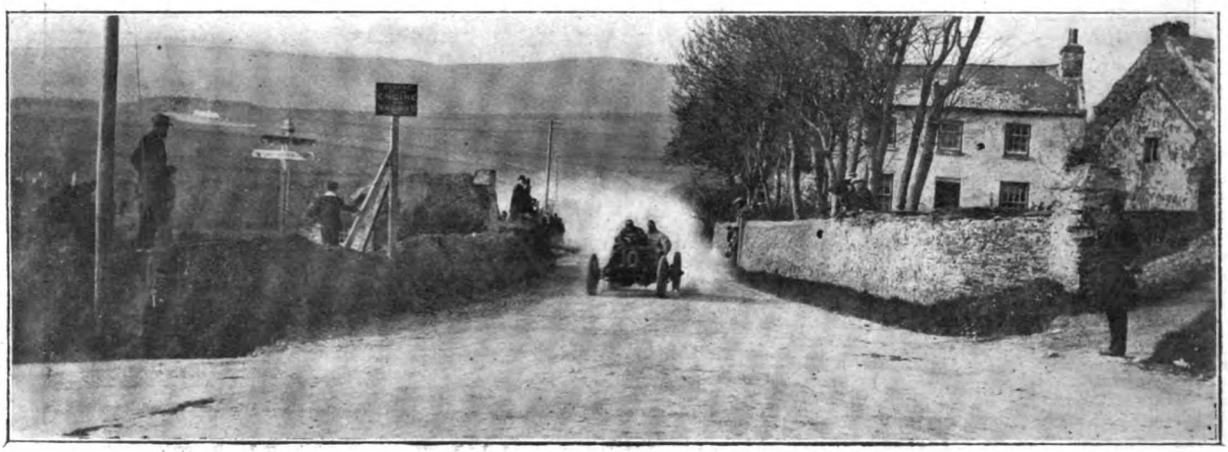

Photo by] The Isle of Man Trials. Mr. S. Girling on the Wolseley passing Creak-na-Mona on his last round. *[D. Collister, Douglas.*

To the Editor of *The Motor-Car Journal.*

Sir,—"Lancelot" should try the "Miesse" steam car, which burns paraffin, and is as fine a hill-climber as it is possible to find. I have never found the burner affected in the slightest degree by wind (the fault of many steam cars), and it gives tremendous heating power. Personally I have driven one for a year and a half with the greatest satisfaction.—Yours faithfully,

Paraffin.

WHEEL *v.* TILLER STEERING.

To the Editor of *The Motor-Car Journal.*

Sir,—In the *Journal* for the 14th inst. "Tillerleve" suggests that experiences as to the above may be of interest. My first car, an old Peugeot, had a vertical pillar, the wheel making three-fourths of a revolution from extreme left to right. I substituted a lever, hinged to turn up out of the way, and about 14 in. long, just short enough to escape catching in my watch chain. This made steering quite easy with one finger on the lever, giving same power as a wheel 28 in. in diameter. My present car, of modern type, had inclined pillar and wheel, which I removed to the right side of the car, and substituted a lever about 2 ft. long, steering with left hand resting on knee. The comfort and ease of this cannot be described without a special extra number of the *Journal* be issued for the purpose. In a lever of this type the handle should not be merely slipped on the end of the straight bar, but should be at the same angle as the modern bicycle handle; this makes a vast difference to the comfort in steering. Of course the lever turns up to give access to the seat.

One advantage of any form of lever steering is the open foot-board

Digitized by Google

giving easy access to the seat, without having to squeeze in behind the wheel and pillar. Having to carry out serious repairs to my present car, I am now fitting for trial an unusual form of lever, vertical, in centre of car, steering with left hand, with straight forward and backward movement, similar to the usual speed changing lever at side of car. This will leave footboard absolutely clear, except for the clutch pedal. When makers find time to consider ease of steering, comfort, and convenience, I do not doubt that lever steering will be more generally fitted, except, of course, to racers, motor omnibuses and the heavier cars.—Yours truly,

A.B. 50.

[It would be interesting if "A.B. 50" would send us a photograph of his steering arrangements when he has completed the alteration.—Ed. *M.C.J.*]

WIRING A DOUBLE CYLINDER MOTOR.

To the Editor of *The Motor-Car Journal.*

Sir,—Having constructed a double cylinder motor of about 5-h.p., and fitted it into a boat with propeller and everything complete, I find that the coil will not spark. Having got the loan of a good trembler coil, the motor now goes away without any trouble. The coil was bought second-hand, and I cannot afford to buy another new coil.
